INDEX.

- Abbey, O. L.—Wound of perineum and urethra; retention of urine; traumatic stricture; aspiration of bladder, 170.
- Abdomen, wound of, 577; contusion of, 753.
- Abdominal section done for ectopic gestation, 249; distention, sulphate of magnesia in, 538; for disease of uterine appendages, 798; section, 832.
- Abortifacient, quinine as, 829.
- Abortion, treatment of, 300, 307, 443.
- Abortionist brought to grief, 629.
- Abortive treatment of typhoid fever, 144; of furuncles, 263.
- Abscess psoas, 18; pelvic, drainage of, 462; of both ovaries, 576; of cornea, 734; ischio-rectal, 807; of spleen 810.
- Absorption, spontaneous, in empyema of children, 365.
- Accidents in prescribing, 391; service, 437.
- Acetone and diacetic acid in urine, 310.
- Acid, salicylic and iron, 129; in food, 616; boracic for leucorrhœa, 155.
- Acid, carbolic poisoning, 365; hydrochloric in removal of necrosed bone, 428; carbolic in hydrocele, 569; sulphuric poisoning, 766.
- Acids in canned goods, 592.
- Acne, 823; treatment of, 714.
- Actinomycosis, case of, 842.
- Acute, mania treatment of, 80; polymyositis, 461; rheumatic peritonitis, 680.
- Address to Medical Societies of the United States, 834.
- Adenitis, axillary in tuberculosis of lung, 546.
- Adulteration of food, 123; of morphine, 268.
- Ady A.—Plugging the nostrils, 161; Large doses of morphia, 227, 270; Quinine in pneumonia, 302; Persistent priapism, 559; Experience with veratrum viride, 671; Hemorrhage into an intra-peritoneal pus cavity, 815.
- Agaricin used in Bellevue Hospital, 191.
- Albuminuria among the sick, 253.
- Alcohol in high latitudes, 525; and its uses, 764.
- Alimentation in phthisis, 235.
- Allen H.—Some old-time prescriptions, 39.
- Allyn H. B.—Treatment of ringworm of the scalp, 106; Hypnotism and its curative uses, 703.
- Almen's test for sugar, 370.
- Alopecia areata treatment of, 215.
- Ambergris, large piece of, 660.
- Amenorrhœa, 90.
- Ammonia-picrate, in malarial fevers, 189.
- Ammonium and iron in hypertrophy of spleen, 179; chloride of in diseases of liver, 785.
- Amnesia, verbal due to shock, 690.
- Amusing experiences of a druggist, 434.
- Anæmia or chlorosis of girls, 854.
- Anæsthesia, by vibration, 27; cocaine, 118; dental, 300; local, 604.
- Anæsthetic, bichloride of methylene an, 12; warm ether an, 95; Parson's local, 366.
- Analgesics, antipyrin and antifebrin as, 184.
- Anderson, Winslow.—Prescription writing, 510.
- Angina pectoris, hysterical, 213.
- Analysis of beer, 563; of cure for cancer, 689.
- Anarsarca due to heart trouble, 109.
- Anatomy, section on, 382.
- Anchylrosis, fibrous, of knee-joint, 197.
- Anemia, pernicious, 656.
- Aneurism cured by position, 53; innominate, 86; ligation of subclavian artery for, 469; of left ventricle, 542; of leg, 545; of aorta in childhood, 549; of aorta cured by operation, 778; of aorta, 841.
- Animals, wild, diseases of, 258; diphtheria in, 61; foot and mouth disease of, 805.
- Antifebrin, the new antipyretic, 119; solvent for, 273; in fevers, 551; in hay-fever, 883.
- Antipyretic treatment in croupous pneumonia, 1; antifebrin, the new, 119.
- Antipyrin, 687; in thermic fever, 171; an analgesic, 184; in pregnancy, 581; in intercostal neuralgia, 849; in hay-fever, 883; in headache and epilepsy, 21; in subcutaneous injections, 222; in headaches, 71.
- Antisepsis for urethra and bladder, 844.
- Antiseptic, iodoform, 82; dressing, 165; system of surgery, 250; sponges, 268; rules, 319; practice, position of, 405; value of coffee as an, 648; corrosive sublimate as, 649; duels, 661; biniodide of mercury an, 759.
- Aorta in childhood, aneurism of, 549; aneurism cured by operation, 778; aneurism of, 841.
- Apomorphine in whooping cough, 155; in respiratory diseases, 557.
- Appendix vermiformis, inflammation of, 697.
- Argument and ridicule, 466.
- Aromatics and bacteria, 267.
- Arteritis, gangrene due to, 131.
- Artery, iliac, ligation of, 526; coronary, atheroma of, 542.
- Arthritis of knee, 773.
- Articular rheumatism, 214.
- Artificial diabetes, 259; fecundation, 777.
- Asthma crystals without asthma, 647; cured by relief of constipation, 783.
- Aspinwall, John.—Correction about honey, 469.
- Aspiration of bladder, 170.
- Association of medical superintendents of the insane, 49.
- Ataxia, locomotor, 292, 631.
- Atheroma of coronary artery, 542.

- Athletes. of interest to, 725.
 Atropia injections for gonorrhœa, 192; in dilatation of pupil, 572; in opium poisoning, 573.
 Atropine, santionate of, 85; stimulating action of, 484.
 Aulde, John.—treatment of common uterine affections, 279; administration of quinine, 301; strophanthus hispidus, 346; small doses, 738.
- Bacteria, are tumors caused by, 181; and aromatics, 267.
 Bacterial cultures, 542.
 Bacteriotherapy in splenic fever, 811.
 Bacilli, typhus in blood, 390.
 Bacillus, ode to, 275; of scarlet fever, 297.
 Bacteriology vs. chemistry, 650.
 Barnes, S. P.—Menstruation, 881.
 Barton, J. M.—Details of antiseptic dressing, 165.
 Base ball injuries, 44, 162.
 Bates, Jas.—Base ball injuries, 162; gonorrhœa, 270.
 Baths, oxygen, in febrile conditions, 179; Turkish, in diseases of circulation, 517.
 Battey's operation, 482.
 Bauer, Louis.—Fibrous ankylosis of knee, 197.
 Bay rum trade-mark case, 629.
 Beauty, personal, and romantic love, 435.
 Be bugs, urticaria from, 188.
 Beer, why it is bitter, 66.
 Belladonna in diabetes, 181.
 Benjamin, D.—The present position of antiseptic practice, 405; Improved splint, 700.
 Bennett, S. A.—Correspondence, 881.
 Benzol, in whooping-cough, 886.
 Bergeon's method, 192, 200, 223.
 Berlin letter, 289.
 Beverage, influence on digestion, 84.
 Bichloride of methylene, 31; anæsthetic, 12.
 Biliary calculi with absence of gall bladder, 553.
 Billings, F. S.—Pathological and Biological Work, 849.
 Biological and Pathological Work, 849.
 Births, still, 609.
 Bismuth, iodide, for chancre, 624.
 Bisulphide, carbon, 162; in pulmonary disease, 87.
 Blackwell, E. T.—Pneumonia, complex in its origin and nature, 133; Purpura hemorrhagica as a complication, 170; Tobacco, safe and unsafe methods of exhibition, 312.
 Blackwood, W. R. D.—Galvano-puncture in tubal pregnancy, 313; Electricity as a means of inflicting the death penalty through process of law, 761.
 Bladder, gas in, 158; aspiration of, 170; in ox, rupture of, 223; inflammation of, 636, 806; diverticula of, 641; foreign bodies, 740; rupture of, 773; antiseptics for, 844.
 Bland's pills, 724.
 Blisters for infants, 26.
 Blood, spitting of, hysterical, 139; typhus bacilli in, 390; portal, in animals; 421; cells, vitality of, 649.
 Blue pus, 784.
 Books disinfecting, 886.
 Boone, D. W.—Atropia injections for gonorrhœa, 192.
 Boracic acid for leucorrhœa, 155.
 Boric acid for sty, 592.
 Bothriocephali, ninety from one patient, 688.
 Bougies, medicated, 269.
 Bowels, internal obstruction of, 812.
 Brains of deaf and dumb, anatomy of, 776.
 Breast, fibroma of, 3; operation for cancer of, 683.
 Breathing pure oxygen, 304.
 Breech presentation with hydrocephalic head, 640.
 Bright's disease, lightning stroke followed by, 110; mental affections with, 709.
 Brobst, J. C.—Egyptian tamarind for hemorrhoids, 640.
 Bromidia, 305.
 Bronchial catarrh, 331.
 Bronchitis from mechanical irritation, 79; eucalyptus in, 618.
 Broncho-pneumonia infantile, 857.
 Browne, Lennox.—An unrecognized cause of many throat ailments, 506, 516.
 Brutality legalized, 502.
 Bunions, about, 805.
 Bundy, A. D.—Medicine in Iowa, 399.
 Burden, conjugal, 863.
 Burial or cremation, 424.
 Burns, treatment of, 121.
 Burr, H. N.—Case of morphine idiosyncrasy, 206; treatment of epistaxis, 553.
 Butterine or margarine, 499.
 Buttermilk in nutrition of invalids, 775.
- Cadavers, preservative of, 216.
 Cecum, tumor near, 751.
 Cæsarean, section on cow, 128.
 Calcareous concretions in external ear, 542.
 Calculi, renal, and white wine, 592.
 Calculous formation, foreign body with, 547.
 Calculus, salivary, 53; in Syria, 457.
 Calkins, A. E.—The etiology and treatment of female sterility, 201; Puerperal mastitis, 539.
 Calomel in hypertrophic, cirrhosis of liver, 681; in diseases of children, 786.
 Camphor and charcoal, 192.
 Camping on Mont Blanc, 432.
 Canadensis hydrastis, 219.
 Cancer, encephaloid, of face, 9; of lip, carcinoma from, 116; uterine, treatment of, 452; lime treatment of, 654; of breast, 683; analysis of cure for, 689; etiology of, 805; bacillus, 886.
 Cannabis Indica, in diarrhœa, 332.
 Canned goods, acids in, 592.
 Carbolic oxide of mercury, in syphilis, 52; acid poisoning, 345; acid in radical cure of hydrocele, 569.
 Carbolsol oil in scarlet fever, 580.
 Carbon bisulphide, 162.
 Carcinoma from cancer of lip, 116.
 Cardiac orifice of stomach, stricture of, 722.
 Carpenter, Wesley M.—Delirium tremens, 791.
 Carotid, ligation of, 581, 778.
 Cataract, 105.
 Carrell, J. B.—Cerebral rheumatism, 705.
 Cascara anarga, 528; sagrada, 657, 712.
 Castor oil draught, 337.
 Castration in epilepsy, 844.
 Catarrh, bronchial, 331; fever, 567; vesical, fluid extract of pichi in, 854.
 Catarrhal vulvo-vaginitis in children, 827.
 Catheterization of ureters, 768.
 Cerebellar tumor, 626, 871.
 Cerebral localization, 277; softening, 467; rheumatism, 705; tumor, removal of, 777.
 Cervical glands, excision of, 116.
 Cinchona growing in Réunion, 565.
 Circinate lesions, purpura with, 564.
 Cirrhosis of liver, 89; with jaundice, 339; hypertrophic of liver, 577, 681.
 Champagne vs. cholera, 755.
 Chancre, iodide of bismuth for, 624.

- Chapped hands, 886.
 Charcoal and camphor, 192.
 Charcot and hypnotism, 230; clinic picture of, 35.
 Charlatan, a regular, 787.
 Chase, M.—Consultation with licensed homœopaths, 497.
 Cheatham, W.—The pupil in health and disease, 41.
 Cheerfulness, 651.
 Chemist, sagacity of, 403.
 Chemistry *vs.* bacteriology, 650.
 Chichipate, 528.
 Childhood, chronic incontinence of urine in, 359; aneurism of aorta in, 549.
 Children, diarrhoea of, 28; scarlatinal uremia in, 258; diseases of, kefir in, 260; aspiration and early incision in empyema of, 365; diseases of, 383; treatment of convulsions in, 431; incontinence of urine in, 559; calomel in diseases of, 786; cure of, 813; nephritis in, 820; catarrhal vulvo-vaginitis in, 827; over excitement in, 846; gonorrhœa in, 853.
 Cholera, 614; infantum, treatment of, 91, 224; in South America, 733; no fear of, 465; infection, investigation of, 516; in New York, 535, 629; *vs.* champagne, 755.
 Chloride of ammonium in diseases of liver, 785.
 Chloroform, recent literature on, 146; in spasmodic croup, 738; death under, 777.
 Chlorosis, 56; supra-orbital neuralgia in, 112; of girls, 854.
 Chorea cured by typhoid fever, 778.
 Chronic rheumatism, 172; laryngitis, its sequelæ, 426; diphtheria, 615; peritonitis, laparotomy for, 809.
 Chyluria, 869.
 Clairvoyante diagnosis, 274.
 Clark, H. H.—Ligation of the third part of the right sub-clavian artery external to the scaleni muscles, for aneurism; death on the seventeenth day from abscess of the sac and septicæmia, 409.
 Clavicle, fracture of, 796.
 Cleansing the hands, 214.
 Climatology and demography, 383.
 Clitoris, ligation of, 882.
 Cocaine in cure of tetanus, 94; anæsthesia, 118; in tonsillitis, 213; influence of, 283; in strictures of urethra, 427; in labor, 429; ligation of external iliac artery under, 526; hydrochlorate of, 604; in diseases of stomach, 745; poisoning with, 843; in obstetrics, 886.
 Cocculus indicus, 401; poisoning from, 431.
 Cockey, C. H.—Medical epitaphs, 497.
 Cod-liver oil, emulsion of, 525.
 Coffee, antiseptic value of, 648; and tea, 658.
 Cohen, S. S.—Alimentation in phthisis, 235; Some practical points in connection with catarrhal fever, 567.
 Cold, influence on heart, in fever, 888.
 Colic, nephritic, operation for, 812.
 Colleges in good standing, 274.
 Collodion iodol, 688.
 Colonial and international congress on inebriety, 34.
 Colvin, D.—Homœopathy, 59.
 Comma bacilli, injection in pigs, 182.
 Composition for removing ink, 400.
 Comstock, T. G.—Scarlet fever, 60.
 Conception, act of, 619; products retained, 867.
 Condurango bark in diseases of stomach, 390.
 Congenital myomas, 421; dislocation of hip, 425.
 Congestive headaches, 545.
 Congress, funds for, 228; of American physicians and surgeons, 597.
 Conjugal burden, 863.
 Conjugal question, 572, 592, 643, 751; woman's view of, 468; man's side, 497.
 Conjunctive, hemorrhage from, 527.
 Consciousness after decapitation, question of, 366.
 Constipation, habitual, gravel purgative in, 182; chronic, treatment of, 681; asthma cured by relief of, 783.
 Constriction, tetanoid, of uterus, 843.
 Consultations with licensed homœopaths, 497.
 Consumption, treatment of, 37, 120, 224.
 Contagiosa eczema papulosa, 189.
 Contention, a bone of, 195.
 Contributed articles, 466, 469.
 Convulsions, epileptic, temperament in, 215; epidemic of, 367; in children, treatment of, 431; puerperal, 642; pilocarpine in, 682; unilateral, 707.
 Cooper Hospital, Camden, N. J., 130.
 Coriaria thymifolia, 35.
 Cornea, transplantation of, 98; abscess of, 734; ser-piginous ulcer of, 735.
 Corrosive sublimate, 587; antiseptic, 649.
 Corset, evil effects from, 786.
 Cough, whooping, treatment of, 87; eucalyptus in, 618.
 Country practitioners, urine examined by, 153; in Texas, 269; experience of, 584.
 Cranium, gunshot wound of, 772.
 Cremation, by Boarry system, 83; or burial, 424.
 Creoline, 872.
 Creosote, effect produced by, 94.
 Cricoid cartilage, extirpation of, 481.
 Criminal, shall a doctor inform on a, 584; gait of, 400.
 Criticism, ill-natured, 848.
 Crothers, T. D.—Inebriety and inebriate hospitals in America, 637.
 Croup, chloroform in spasmodic, 738.
 Croupous pneumonia, 671.
 Crown Prince's throat, 651.
 Curability of tabes dorsalis, 389.
 Cyst, post-rectal dermoid, 648.
 Cystic ovaries, 116; enlargement of vulvo-vaginal gland 151; sarcoma of inferior maxilla, 771.
 Cystotomy, 806.
 Cysticercus in anterior chamber of eye, 844.
 Dangerous toy, 501.
 Darwin as a medical student, 885.
 Datura seeds, poisoning by, 591.
 Dead failure, limited, 216.
 Deaf, intermarriage of, 683; and dumb, anatomy of brains of, 776.
 Death, after a dog's bite, 127; from pollution of well, 130; in dentist's chair, 401.
 Decapitation, question of consciousness after, 366.
 Deglutition of air, 118.
 Delirium tremens, 791.
 Delivery of after-coming head, 769.
 Dental anesthesia, 300; and oral surgery, 382.
 Dentistry, in Germany, 67; for country practitioner, 398; American, an English opinion of, 661.
 Dentrifice, steatite as, 65.
 Dermoid cyst of the ovary, 714.
 Destroyers, the two, 65.
 Detection of a criminal by a doctor, 562; of metallic bodies with magnet, 714.
 Deviations of the septum narium, 183.

- Deweese, W. B.—Pregnancy complicated with hydroperitoneum, 573.
- Diabetes, 485; new remedy for, 51; action of belladonna and opium in, 181; artificial, 259; melitus, etiological factor in, 233; patient in search of health, 329; jambul in, 654.
- Diagnosis of simulated joint-trouble, 66; brilliant clinical, 180; of clairvoyante, 274; error in, 554; of a layman, 566.
- Diaphragm, rupture of, 618.
- Diarrhoea of children, 28; treatment of, 218; summer, treatment of, 224; cannabis Indica in, 332.
- Diet on health, influence of, 589.
- Differential diagnosis of tuberculous meningitis, 581.
- Digestion, infused beverages on, 84.
- Dilatation, treatment of piles by, 122; of pupil, 300, 572; of stomach, 541.
- Diller, Theo.—Gangrene of the lung complicating croupous pneumonia, 671.
- Diphtheria, 721, 814; epidemic of, 14; treatment of, 225; in animals, 501; circumscripta, 547; chronic, 615.
- Diseases, pulmonary expectorants in, 74; of wild animals, 258; kefir in, of children, 260; treatment of, 261, 298; of joints, 357; bark of condurango in, of stomach, 390; heart, treatment of, 490; Turkish baths in, of circulation, 517; terebene in, of lungs, 555; apomorphia in respiratory, 555; hip joint, 729; cocaine in, of stomach, 745; chloride of ammonium in, of liver, 785; calomel in, of children, 786.
- Dislocation, congenital, of hip, 425; of scapula, 617; of thoracic viscera, 618.
- Disinfectant, iodine as, 647.
- Disinfection, 552.
- Disocorine in hepatic colic, 268.
- Distilled water, in eye lotions, 33; not good for eye lotions, 305.
- Distillery swill a food, 554.
- Diverticula of bladder, 644.
- Dock, Geo.—Sulphuric acid poisoning, 766.
- Doctor shot, 26; in trouble, 230.
- Doctor's story, 306; good place for, 691.
- Doses, large, 608; small, 738.
- Douche in puerperal septicemia, 345.
- Drainage in pelvic abscesses, 462.
- Dressing, sterilized, 81; antiseptic, 165; sanitary reform in, 560; for broken finger, 591.
- Drink for harvest field, 590.
- Drinkers, moderate, duration of life in, 813.
- Dropsy, pilocarpus in, 559.
- Druggist, duties of, 98; experience of, 434.

PHILADELPHIA, JULY 2, 1887.

VOL. LVII.—No. 1

ORIGINAL DEPARTMENT.

A CASE OF DOUBLE CROUPOUS PNEUMONIA IN A CHILD, WITH REMARKS ON ANTIPYRETIC TREATMENT.

BY WILLIAM PEPPER, M.D., LL.D.,

Professor of the Theory and Practice of Medicine and
Clinical Medicine, at the University of Pennsylvania.

The following case appears worthy of being placed upon record on account of its pathological and clinical interest. On December 2d, 1886, I was called to see F——C——, a boy, aged three and one-half years, who had been under my professional observation from the time of his birth. Born of healthy parents, he has exhibited a marked tendency to catarrhal trouble, chiefly affecting the gastro-intestinal canal. In the summer of 1885 he had entero-colitis, and in the fall had a violent attack of dysentery, which was ushered in with high fever (105°), and a fully developed convulsion. He made a good recovery and enjoyed good health during the ensuing year, returning to Philadelphia from the seashore, in October, 1886, in unusually good condition. He was always watched carefully and was exposed to no appreciable cause of sickness. In November, he began to exhibit catarrhal symptoms, affecting in a slight degree, the respiratory and digestive mucous membrane. He was confined to the house for at least two weeks prior to the onset of the attack now to be described, which occurred on December 2d.

He was noticed to become suddenly very hot, and, at the same time to grow dull and

heavy. I was summoned hastily, but before I reached the house he had a severe convulsion. The rectal temperature was 107° . After the convulsion he was heavy and dull and almost unconscious, but this state was disturbed by recurrence of severe convulsions at short intervals. He was immediately placed in a tepid bath, the temperature of the water being reduced until it was quite cool, and until his temperature fell to 104° . It rose again almost immediately after his removal from the bath, and the repetition of this measure did not produce any more lasting effect. Antipyrin was then given in the dose of three grains, repeated in three hours. The effect was very prompt and satisfactory. The temperature fell to $103\frac{1}{2}^{\circ}$, the skin became moist and relaxed, and the rectal temperature did not rise above 105° for several days. Careful exploration revealed no physical signs in connection with either the lungs or the heart. A close watch was kept for the appearance of eruption, but the second day passed without any such symptoms. Not until the third day, was it possible to make a positive diagnosis. At that time a fine crepitant râle was heard over the left lower lobe posteriorly, and this was soon followed by the development of complete pneumonic consolidation of the whole lower lobe, with an extension to the posterior half of the upper lobe. The child was very ill, with temperature ranging from $103\frac{1}{2}$ to 105° , with rapid, weak pulse, and with very hurried breathing. The urine contained no albumen or casts, but presented the febrile characteristics in high degree, with an almost entire absence of the chlorides. The stomach was retentive, but it

was very difficult to induce him to take nourishment or medicine. On the 6th day there was a sudden rise of temperature to over 106° , with the appearance of threatening spasmodic movements. Antipyrin was at once given as previously, with equally good results. The physical signs of pneumonia of the posterior part of the right lung now appeared speedily, and went on to complete consolidation of the posterior half of the lower and upper lobes. From the 9th to the 20th days, it seemed scarcely possible that the child could survive from day to day. But the temperature, however, did not rise above 105° , and it was not thought necessary to resort to antipyrin again under these circumstances.

The respirations were from 60 to 80 in the minute, and the pulse ranged from 150 to 160. The cough was short, dry, and not very frequent or painful; there was no return of convulsions. The nervous symptoms consisted of great dullness alternating with spells of extreme irritability or delirious excitement; there were extreme debility and rapid loss of flesh. In addition to the occasional administration of antipyrin, as above mentioned, the treatment consisted in the use of quinia by suppository, four grains being given three times daily; and of ammonium carbonate, one grain every two hours, with, at first, tincture of aconite root, and after the eighth day, with tincture of digitalis. By the fifteenth day it had become impossible to administer the above remedies by the mouth, and the use of suppositories was followed by diarrhea; scarcely any food could be given. The signs of resolution were very slow in appearing, and the severity of the general symptoms was maintained. At this time an emulsion of cod-liver oil with lacto-phosphate of lime, which the child had taken willingly on several occasions for catarrhal attacks, was tried, and to my surprise was received with immediate favor, so that a large teaspoonful was given every three hours for a considerable time; brandy was given freely after the eighth or ninth day. The tendency to diarrhea was checked by injections of laudanum and starch water. Defervescence began about the eighteenth day of the attack, and, although not abrupt, was quite rapid, so that a temperature of 100° to 101° was reached by the twenty-first day. Even after this, however, the consolidation on both sides was very extensive, resolution advancing from below upwards and being more forward on the left side, which had been the first attacked. No expectoration occurred at any

time, the enormous amount of exudate being absorbed.

Temporary albuminuria of moderate degree, without casts, appeared during this stage of resolution, but passed away wholly subsequently. The consolidation was not entirely removed until the thirtieth day. The child was then a mere skeleton, barely able to move his hands, and unable to bear any weight upon his legs for six weeks subsequently. There were no sequelæ except a tendency to rectal irritation and diarrhea to which the child had been subject since his spell of dysentery. About April 15th, he had practically regained his health, and at this time he is stronger and fatter than he has ever been in his life.

The origin of this case of croupous pneumonia is obscure. As stated, the child had been confined to the house for at least two weeks prior to the onset of the attack. It is true that his system was extremely sensitive, and that the season was a very severe and inclement one; so that he may have been chilled in some accidental way. The sanitary condition of the house was good and there has been no sickness among other members of the family. The diagnosis was very difficult for the first three days. It is of course well known, that in some cases of croupous pneumonia, the general symptoms precede by a day or two the appearance of the local signs. But the violence of the onset here was such, presenting convulsions and stupor and rectal temperature of fully 107° , as to strongly suggest scarlet fever, occurring as this case did in an unprotected child. There was no enlargement of the glands at the angles of the jaw, and the mental condition made it impossible to determine if there was any sore throat. As there was a sister, a girl five years old, also unprotected, isolation was insisted upon until the nature of the case developed itself.

In estimating the gravity of the onset and the cause of the initial convulsion, it was of course remembered that an acute local affection occurring a year previously, had been attended with convulsion when the temperature reached 105° . I may here remark that the course of this dysentery and the readiness with which it yielded to rectal medication seemed to prove its local nature, and that there was no specific constitutional element present. This encouraged the hope that in the later attack also, it would be found that a developing local lesion was the essential cause. The interval between the appearance of the initial symptoms and the earliest demonstrable physical signs of pneu-

monia was unusually long. The chest was examined critically several times a day, and I believe it may be stated positively, that it was not until well into the third day that the crepitant râle first appeared. The action of antipyrin in this case is deserving of special attention. It was evident that the hyperpyrexia was, in large measure, directly productive of the grave nervous symptoms, and that unless it were reduced, a fatal result would speedily follow. It is difficult to overestimate the importance of meeting promptly such violent onsets in acute cases. While in adults the temperature may not go so high nor the nervous symptoms be so alarming, there is great room to fear serious damage to the heart muscle, the blood and the nerves. In children the fear of rapid and irreparable damage is even greater. The continuance of such excessive temperature for even a few hours will impart an added gravity to the case, which may determine its future course in a fatal direction. It would seem good practice to meet the abrupt development of such symptoms by remedies capable of antagonising them instantly.

Quinia and veratrum viride are too slow. Venesection may be the best remedy in suitable cases, but cannot be advised in childhood. The uncertainty of diagnosis in such cases as the above would add to the impropriety of resorting to it. The prompt use of cold water externally, or the administration of some antipyretic of immense power, are the only alternatives. The material is not yet at hand to decide as to the relative merits of the cool bath and of the remarkable new remedies antipyrin and antifebrin. It is clear that the former measure, the cool bath, does more than merely abstract heat; it exerts a positive action upon the state of the skin and of the nervous system. But so also do the latter named remedies cause other effects, both direct and indirect, than the mere reduction of the temperature. The question of the relative merits of these two modes of antipyretic treatment, and the determination of the cases which are best adapted for their respective use, is one of the most important clinical problems of the day. In continued fevers such as typhoid fever and scarlatina, where the hyperpyrexia is largely due to the poisoned state of the blood, even though there may be local irritative lesions which play a part in heightening the fever, the good results from antifebrin or antipyrin will often be found to be very transient; and if the doses of these remedies be pushed, it may be doubted whether injurious effects may not follow. In such cases it is probably

safest to suspend their administration after a few doses, and to try the effect of cold water externally; and if then its effect be no more permanent, to abandon antipyretic treatment in the hope that the case will run a more favorable course, even though the temperature be excessive, than if complicated by the repeated use of perturbative and ineffectual antipyretic measures.

But the brilliant results which may sometimes be attained from antifebrin and antipyrin can find no better illustration than in cases like the one here reported. It is impossible to draw any inferences from the superior efficacy of the external remedy to the cold bath in this single case, but it is very desirable that all should appreciate that we have recently had put into our hands agents of great power, very manageable when given in suitable and not too frequently repeated doses, and singularly free from any attendant ill-results.

The willingness with which the emulsion of cod liver oil was taken, and the apparent improvement which followed its use in this grave acute case, were noteworthy.

1811 Spruce Street.

FIBROMA OF THE FEMALE BREAST; BASED UPON A STUDY OF ONE HUNDRED CASES.

BY SAMUEL W. GROSS, M. D., LL. D.,
Professor of the Principles of Surgery and Clinical
Surgery in the Jefferson Medical College
of Philadelphia.

NEOPLASMS composed of hyperplastic connective tissue, in which normal or variously altered preëxisting acini and ducts are sparingly interspersed, are classified as fibromata. From the persistence mainly of the acini, they are included by Birkett in his first group of adenomata or adeno-sarcomata, which he describes as being "compact, dense, firm, fibrous, lobulated, and invested by their own fibrous capsule;" and they are synonymous with the solid fibroid glandular tumors of Foerster, the adenomata with predominance of stroma of Broca, the *corps fibreux* of Cruveilhier, the chronic mammary tumors of Sir Astley Cooper, the pancreatic sarcomata of Abernethy, the adenoid tumors of Velpeau, the partial hypertrophies of Lebert, and the adenocèles of Bryant. That they form at least a part of the mammary glandular tumors of Paget is evident from the statement, that the connective tissue was very abundant in most of the specimens he had examined. From the very frequent presence

of preëxisting lacteal glands in their midst, Green, Duplay, Billroth, Erichsen and Beck term them adeno-fibromata. Klebs and Ziegler recognize an almost pure fibroma and an adeno-fibroma; while Virchow, Rosenstirn, Monod, Cornil and Ranvier, Lannelongue, Tripiër, Labbé and Coyne, Perls, and other modern investigators describe them merely as fibromata. The proliferous or vegetating variety, properly denominated cystic fibroma, is equivalent to the papilläre Drüsengeschwulst of Foerster, the cytosarcoma fibrosum of Rindfleisch, the fibroma intracanalicular of Virchow, the fibroma endocanalicular of Labbé and Coyne, the cystoid adenoma of Birkett, the true cystic adenocoele of Bryant, the proliferous mammary cyst of Paget, the hydatid or encysted tumor of Sir Astley Cooper, and the tuberous cystic tumor of Caesar Hawkins.

Fibromata are circumscribed, spherical, rounded, or ovoid, and have a nodular, bossed, or lobulated outline. Their consistence is usually firm and elastic, or hard when they are not succulent, or unequal when the fluid contents of the cysts are in excess, in which event they are elastic, or soft and fluctuating over the more prominent bosses, but firm elsewhere. On section they may be dry, white, nacraceous, or opaque-white, dense, and compact, and cry under the knife, and the interlacing bundles of fibrous tissue may be arranged concentrically around centres which project above the level of the cut surfaces. Minute examination of growths which present these peculiarities shows that they are composed of dense bundles of mature fibrous tissue, which is almost or entirely devoid of corpuscles, and that the small projections correspond to ducts and acini. This type corresponds, therefore, to the neoplasms formerly called fibroid or desmoid. In other specimens, as in Fig. 1, from Formad,* bands of wavy, connective tissue interlace in every direction. Such tumors are more or less juicy or moist, and of a glistening whitish, grayish-white, or rosaceous tint, and represent the majority of fibromata. In rapidly growing examples the minute structure is that of recent connective tissue abounding in cellular elements.

From the foregoing brief description it will be seen that the determination of fibroma depends upon the predominance of the fibrous tissue over the preëxisting glandular structures. It is very rare to find glandular elements entirely absent, but when present they must be subordinate to constitute a fibroma. When they are newly formed and preponderate over the fibrous constituent of the tumor, the latter is an adenoma, as is beautifully shown in Fig. 2. from Formad, which is introduced here with a view to compare the histological features of these

FIG. 1.

FIBROMA.—The newly formed fibrillar connective tissue is loose and wavy, and transverse cuts of bundles of fibres are seen at many points. In the upper portion of the drawing is a duct in transverse section, the epithelium of which has undergone irritative hyperplasia. $\times 300$.

two growths, and to show precisely what is meant by the term fibroma.

The smallest vegetating tumors have a lobed appearance, while the macroscopic features of the larger ones vary in accordance with the transformations to which they are liable. Thus, while the mass of the growth may be firm and of a milk-white color, the vegetations are not infrequently softer and more transparent. When they are very vascular, their tint is rosaceous, or decidedly red, or red in lines, or even ecchymotic. A yellowish hue is indicative of fatty changes, while myxomatous degeneration is characterized by areas of gelatinous appearance.

Inflammation and suppuration of fibromata are very uncommon, and fungous protrusion was met with in only five of the one hundred

* I am indebted to Dr. H. F. Formad for this and the succeeding illustration, which are taken from his forthcoming "Manual of Microscopic Diagnosis."

cases which I have collated. It is interesting to note, from a diagnostic standpoint, that these were all examples of vegetating growths, and that the skin around the ulcer was normal as respects freedom from infiltration and adhesion to the protruding mass.

In a unique case recorded by Satterthwaite,* a proliferous fibroma protruded through the dilated orifices of the milk ducts, without the intervention of ulceration, so that the nipple was surrounded by a mass of tissue which was eight lines high, and looked like exuberant granulations.

The degenerations and transformations of fibromata are the cystoid, fatty, myxomatous, osseous, calcareous, and telangiectatic; but they are infrequent. In about 3 per cent. of all examples they may be the seat of cysts, due either to fatty or mucoid transformation of the epithelium of the acini, or to myxomatous change of the connective tissue. In addition to the latter, there may also be fatty metamorphosis, and in this event the growth may contain blood or extravasation cysts. In 4 per cent. of all cases, provided they are of many years' duration, the mineral salts may be interspersed throughout limited portions of the mass, so as to impart to it the appearance of spongy bone; or they may be aggregated into a densely hard concretion, which, as recorded by Cruveilhier,† may resemble in size and configuration the head of the femur; or, as in the case of Monteils,‡ they may form plates surrounding the fibrous tissue, some of which contain osteoblasts. Ossification is very uncommon, the only example of that occurrence of which I have any knowledge being one of a true spongy osteoma, as large as a pigeon's egg, contained in a cystic myxomatous fibroma removed by Leloir.§

Although they are, as a rule, only moderately vascular, fibromata undergo telangiectatic transformation in 6 per cent. of all instances, which is usually associated with rapid growth, and is indicated in one half of the examples by a bloody discharge from the nipple. In these cases of increased vascu-

larity, which, as well as the calcareous degeneration, appears to be confined to the cystic fibromata, the vegetations are pervaded by large vessels, to the rupture of which may be ascribed the more or less transformed blood that is found in the dilated ducts, and the hemorrhages which occur when they protrude externally.

Fibrous tumors of the mamma are usually solitary. Thus, of 100 examples, which include twenty-four of my own, only 15 were multiple, two growths being present in one breast in five, one in both breasts in five, two in both breasts in four, and three in both breasts in one. In the last case, which was

under my care in March, 1887, I enucleated three fibromata from the right breast, which had existed, respectively, for twenty-four, five, and two years, and, after amputating the left mamma for carcinoma, discovered that, in addition to the malignant growth, it contained three small fibromata. The patient, who was fifty-one years of age, single, and still menstruated regularly, continues well.

When single they are, for the most part, peripheral, their favorite locality being the upper and outer portion of the left breast. Thus, of 85 cases in which the seat is noticed the tumor occupied—

They are generally quite superficial, and, in rare cases, or once in every twenty-five, project beyond the level of the skin as pendulous or pedunculated growths.

They are met with as early as the seventh and as late as the seventy-fourth year, the average age of their first observation being 29.1 years, but they are uncommon before puberty and after the fifth decade. Of the 96 cases in which the age is noted—

19 appeared between 10 and 19 years.

Of the entire number, 7, or 7.29 per cent., occurred before the sixteenth year, namely at the ages of 7, 12, 13, 14, 14, 14, and 15, or during the developmental state of the mamma; 67 or 69.79 per cent., appeared between the sixteenth and fortieth years, or at a period when the breast and the genital organs are functionally most active; and 22 22.91 per cent., after the fortieth year, or during the period of their functional decline. It is, moreover, interesting to note that cystic fibroma develops later in life than the solid variety, since the average age at which the former was first noticed was 38.42 years, against 25.54 years for the latter. Hence it may be said that non-vegetating fibromata, which represent 63.54 per cent. of the entire number, are essentially outgrowths of the young and active mamma, while vegetating fibromata are outgrowths of the mature gland.

In the unique case of fibroma in childhood, recorded by Dr. Hopkins,* of Brooklyn, a tumor as large as a chestnut was enucleated from the right mamma of a girl seven years of age. At the end of six months, a small growth was noticed in the left breast, and two years later it had attained a diameter of one inch. At the expiration of five months, the entire breast, with four enlarged axillary glands, were removed. Sections of the growth examined by myself developed that it was made up of wavy fibrous tissue, in which were intercalated a few ducts.

Thirty-nine of the patients were single when the tumor was first observed, and

thirty-six were married, while the social condition is not stated in the remainder. Of the married women, twenty had more than one, and seven had one child, but four of these had never suckled; six were barren; and the question of children is not mentioned in three. In two the disease developed during lactation.

Of fifty-five cases, in which the menstrual function is recorded, forty-nine were regular, five were irregular, and one was the subject of metrorrhagia. Two of the patients after the fiftieth year were menstruating, while of the young subjects it is certain that the catamenia had appeared in one at the age of fourteen. Assuming, in the remaining six, and in five women after fifty years, that the menses had either not appeared or had ceased, it is evident that fibromata are developed principally during the menstrual epoch of life. These facts, when considered in connection with the statements concerning the social condition of the patients, demonstrate conclusively that neither celibacy nor disordered nor arrested menstruation is an important agent in their production.

In only fourteen instances, or in about one in every seven, was the tumor traceable to injury. In one there was antecedent mastitis; in two the mothers of the patients died of mammary cancer; while in one it appeared to be transmitted from parent to child. In the last case, recorded by Puls,† the left breast of the mother was the seat of two vegetating fibromata, while two cystic tumors were present in the left breast of the daughter. The general health of the patients was, as a rule, excellent.

The growth of fibromata is slower than that of the other connective tissue tumors, but it is very variable, and seems to be influenced by the presence or absence of vegetations. Of the solid variety, the smallest that I have met with attained a diameter of half an inch, and a thickness of three-eighths of an inch, in twelve months, and my experience shows that they rarely exceed the volume of a large walnut in three years. Even at the end of ten years they may be limited to that size,‡ or measure only three inches in diameter in eighteen years.§ A breadth of

§ Muriel, *Trans. Path. Soc. London*, vol. viii, p. 384.

an inch and three-quarters in six months is the most rapid growth that I have witnessed. The largest examples that I find recorded were of the size of a goose's egg in four years,* or of an adult hand, and weighed three pounds and a half in five years † or measured nearly twelve inches in length, and weighed seven pounds in twelve years; ‡ or had a circumference of twenty-two inches, and weighed four pounds in twenty years; § or attained the volume of two fists, and weighed upward of twelve pounds in twenty-one years. || On the whole, the rate of their growth may be computed at about two-thirds of an inch a year.

Cystic fibromata increase more quickly and acquire a larger size, as a rule, than the preceding variety. While it is true that they may require twelve months to reach the volume of a small chestnut, ¶ or six months, ||| eighteen months, ** two, |||| three, |||| and even four years, |||| to attain the dimensions of a hen's egg, they grow, on the other hand, to the size of a double fist or foetal head in two years and a half †† or six years, †† of an adult head in one year, §§ eight years |||| or twenty-five years, ¶¶ or have a circumference of twenty-nine inches, and weigh eight pounds in six years, *** or weigh twenty-nine pounds in seven years. ††† A peculiarity of their growth is that, while they may have been stationary or have progressed slowly for a long time, they suddenly, and without obvious cause, begin to increase rapidly, so that a nodule that has remained of the size of a walnut for five years and a half reaches the volume of a double fist in six months, ††† or a tumor which has taken twenty-four years to equal the size of an orange attains that of an adult head, and weighs nearly six pounds in an additional year. §§§ Under these cir-

cumstances the neoplasm will be found to be very vascular, or contain blood-cysts, or a large quantity of fluid. Hence the mode of increase is of importance as an aid in the diagnosis of the variety of fibroma, a slowly and regularly growing tumor indicating freedom from cysts and vegetations, and a suddenly and rapidly increasing tumor, with decided enlargement of its bosses, indicating the accumulation of fluid contents and intracanalicular vegetations.

It now and then happens that fibromata grow very rapidly during pregnancy, as in the case reported by Cras, while, in about four per cent. of all examples, they become larger and softer during the menstrual discharge and subside at its termination, while in one per cent. they became smaller and softer. In one case the tumor became harder and fuller just before the appearance of the menses, but returned to its former consistence and volume when the flow was established. In an instance recorded by Fergusson,* it increased very rapidly after the menopause; while, in a unique example reported by De Morgan, † the breast suddenly doubled its size during a severe attack of gout in the toe, but returned to its original dimensions with the disappearance of the disease.

Throughout their entire life, as a rule, the skin remains mobile and normal in texture and color; the subcutaneous veins are not enlarged; the nipple is natural; the neighboring lymphatic glands are not enlarged; and the tumors are free from superficial or deep attachments.

To these general statements there are some exceptions. In three cases the skin was adherent, but to a limited extent only in two; in four it was red, and in one of these, at points, almost purple; while in five, as has been already mentioned, it ulcerated. The superficial veins were tortuous and dilated in five. The nipple was depressed in three. In two the neoplasm was so closely connected with the pectoral muscle that some of its fibres had to be removed with it; while in another it adhered firmly, by two prolongations, to the periosteum of the sternum. In two instances the lymphatic glands were enlarged.

In one case out of every seven of cystic fibromata there is a discharge from the nipple, but this symptom does not appear to be present in the solid form of fibrous tumor. In an example recorded by Labbé, ‡ a spontaneous, although scanty, escape of a whitish fluid preceded the detection of the new

growth by two months, when it became bloody. In a patient under the care of Guyon,* a sanguinolent discharge was induced by the pressure upon the breast, but it had ceased for several years before the tumor was extirpated. In a third case,† there were several hemorrhages by the nipple during the rapid increase of the tumor, or during the last month of its existence. In a case of my own a yellowish brown fluid could be expressed; while in that of Watson,‡ the discharge was spontaneous. In all of these examples the cysts were more or less completely filled with highly vascular vegetations, so that a bloody discharge is indicative of that condition.

In 35 examples of fibroma pain was experienced. Attention was, however, first called to the affection by suffering in only 3 of the entire number, while in the remainder it declared itself after the discovery of the tumor. In 20, or more than one-half, the pain was of an intermittent, severe shooting, darting, lancinating, or neuralgic character, while in 15 it was slight and evanescent, usually darting, but not infrequently dull and aching. In 9 it did not appear until the tumor began to increase rapidly; in 4 it was experienced only at the menstrual period; in 2 it grew worse at that time, and in 1 during lactation; while in 1 the pain was aggravated after the cessation of the catamenia. In the examples of ulceration of the skin and fungous protrusion, the suffering was slight; in one, indeed, there was no pain at all, but the mass was exquisitely tender on handling. Including this case, only six were sensitive. In one of my own, a tumor not larger than a bean was, for the last three months of its existence, as intolerant of manipulation as a painful subcutaneous tubercle. It had existed for one year in the right mamma of a prolific female, aged forty-two, from whose left breast a similar growth was removed six years previously in Saxe-Weimar. In three examples the pain was neuralgic, paroxysmal and severe, and radiated to the shoulder, base of the neck, axilla and inner side of the arm. Not only were the tumors tender to the touch, but the mere friction of the clothing provoked suffering; while in one the patient was deprived of sleep, appetite, and the use of the corresponding arm. In none of these so-called *irritable tumors of the breast* did the growth exceed the volume of a small walnut. Hence, while it is true that amylenic neuromata occur in the mamma,

as has been demonstrated by Tripiér* in two instances, it is highly probable that the small growths which excite so much suffering are composed essentially of indurated fibrous tissue comprising nerve filaments.

Recurrence of fibromata is met with once in every twenty-five cases. The most remarkable of these is that recorded by Rosenstirn,† in which a tumor of one year's standing, and seated in the left mamma of a prolific woman of forty-five, was enucleated in April, 1855. In March, 1860, a growth of six months' duration was removed from the right breast. Four additional tumors were extirpated from the left mamma in March, 1861, August, 1862, August, 1866, and September, 1869, and two from the right breast in 1862 and 1869. They were all traversed by enlarged and deformed ducts. These illustrations of recurrence do not denote local malignity, but merely indicate that, in some women, there is a tendency to the formation of multiple fibrous growths, so that in these cases it was a question either of the further development of a nodule which was overlooked at the time of operation, or of the successive appearance of similar tumors in portions of the gland that remained behind. In all of these examples the growths were simply enucleated; but even when the gland has apparently been entirely removed, it need not excite surprise if fibromata subsequently make their appearance, since outstanding lobules are sometimes disseminated throughout the entire mammary region, and even in the axilla, and may readily escape the eye of the surgeon.

Other evidences of the innocent nature of fibromata are the absence of enlargement of the associated lymphatic glands and of secondary deposits in the viscera. Their benignity is, moreover, demonstrated by the facts that they had existed, on an average, for five years and eight months before they were subjected to the knife, and that the total duration of life from their first observation to the date of the final reports averaged fourteen years.

Although they are not malignant, fibromata may, in their open and fungating state, prove destructive to life through profuse suppuration and hemorrhage, or through the injurious effects exerted upon neighboring organs. Thus, Foerster‡ describes a solid tumor, eleven inches long, eight broad, and four inches and a half in thickness, which pro-

‡ *Op. cit.*, Bd., ii, p. 481.

duced absorption of a portion of the seventh rib, and penetrated the thorax, where, covered by the pleura, it formed a mass seven inches long, five broad, and three inches and a half thick, which rested upon the diaphragm, pushed the lung upward and completely compressed its lower lobe, dislocated the heart to the right, and curved the vertebral column to the opposite side.

The diagnosis of fibromata is based upon their indolent and insidious origin, their great mobility, peripheral situation, firm consistence, nodular or lobulated outline, slow growth, moderate dimensions for the period of their existence, freedom from alterations in the skin, nipple, subcutaneous veins, and lymphatic glands, slight liability to ulcerate and fungate, and to a discharge from the nipple, slight tendency to be painful during their progress, and upon their greatest frequency between the sixteenth and fortieth years, or, on an average, at the twenty-ninth year.

The only tumors that exist prior to the sixteenth year are fibroma and sarcoma, the former being more than twice as common as the latter. The fibromata are always solid, while the sarcomata are cystic in three-fourths and medullary in one-fourth of all examples; so that a firm solid neoplasm at that period of life is a fibroma and nothing else.

The distinction between the solid and cystic varieties may be made by attention to the following points: The former appear, on an average, at the twenty-fifth year; eleven per cent. develop before the age of sixteen, and sixty-eight per cent. before the thirtieth year. They are uniformly firm or hard, never fungate, nor are they marked by a bloody discharge from the nipple. The latter are never seen before the sixteenth year; occur, on an average, at the thirty-fifth year; and only forty per cent. originate before the age of thirty. Their consistence is unequal, being firm at points, and soft and fluctuating at others, they are more largely and deeply lobulated, fungate once in every seven cases, and discharge by the nipple in an equal proportion of instances. Adhesion and discoloration of the skin, enlargement of the superficial veins, ulceration, depression of the nipple, and deep attachments, features which are uncommon in fibromata, if present, are characteristic of the cystic variety. Their growth is, moreover, sudden and rapid after having remained stationary, or advanced slowly, for several years.

The diagnosis between cystic fibroma and cystic sarcoma cannot in every case be absolutely made without a resort to the micro-

scope, as they possess so many clinical features in common.

The treatment of fibroma is by enucleation from its capsule, the line of incision radiating from the nipple. If an involuting breast be the seat of several tumors, it should be excised, and the entire gland should be sacrificed if the growth be ulcerated. In women of fashion the scar may be hidden from view by adopting the practice of Gaillard Thomas.* When the tumor is of moderate volume, neither very small nor very large, that distinguished gynecologist makes an incision in the fold which unites the lower hemisphere of the breast to the thorax, through which that portion is dissected from its deep attachments, when an incision from the under surface of the breast admits of the removal of the growth. If the operation be aseptic, as all operations should be, and care be taken to drain the cavity left by the enucleation of the tumor, the resulting cicatrix will be scarcely apparent, especially as the greater portion of its extent will be concealed.

In recommending the removal of fibroma, I am not unmindful of the statement that it may disappear after marriage, or during pregnancy, or at the climacteric, but I cannot find the slightest evidence confirmatory of this assertion. Broca† regards compression as an efficacious measure: while other surgeons resort to sorbefacient plasters and unguents. These expedients I regard as not only useless, but as positively detrimental, as they may excite active growth. Nor do I favor the let-alone policy of some surgeons. As I have elsewhere pointed out,‡ fibroma is liable to be transformed into sarcoma and carcinoma; and the cystic variety, if not timely removed, not uncommonly ulcerates, and protrudes large fungous, offensive and bleeding masses. Then, too, a tumor of the breast, no matter what its nature may be, is always a source of anxiety. It is for these reasons that I advise an early operation, as it is the only means which will rid the patient of these risks and annoyances.

SENILE GANGRENE, COMPLICATED WITH ENCEPHALOID CANCER OF THE FACE; SPONTANEOUS AMPUTATION; RECOVERY.

BY CLARENCE G. HOLLISTER, M. D.,
UNION CITY, PA.

The remarkable feature of this case was

* *New York Med. Jour.*, April, 1882, p. 337.

† *Traité des tumeurs*, t. ii, p. 462.

‡ *A Practical Treatise on Tumors of the Mammary Gland*, p. 23.

the wonderful work of nature, hampered by the cancerous cachexia and persistent anemia, from continuous and severe hemorrhages, in separating the dead from the living tissue, making an amputation of which the best surgeon might be proud.

Mr. B., about sixty years old, had for many years suffered from numerous scaly spots upon his face, some of which ulcerated through the integument. About two and a half years ago one of these ulcerated spots rapidly developed into a true cancer, situated upon the right cheek and temporal region. It took on a malignant form and the patient was averse to surgical interference, being somewhat discouraged by the unsatisfactory treatment of his face for many years, so that he failed to call upon any medical gentleman for assistance until the disease had progressed so far as to make interference useless. At the end of about two years he had a large mass of raw cancerous tissue upon his right cheek which bled so profusely as to bring him almost to death's door. On October 16, 1886, he was seized with excruciating pain, commencing in the right-knee and extending to the foot and ankle. It was with difficulty he could be kept quiet for a moment. He said he would rather die than suffer such pain for thirty minutes, which coming from one who had suffered so much, meant a great deal.

Upon examination, no swelling, or heat, or loss of temperature, could be discovered. So far as physical signs were concerned the foot and leg were normal. Repeated hypodermic administration of morphia allayed the pain and gave him some rest. Realizing that there must be some physical signs of the origin of the pain by another day I left him, with instructions to administer the morphia in doses large enough and often enough to control the pain. Upon visiting him the next day, and again carefully examining the leg and foot, I discovered the key to the trouble—a slight coldness of the foot, extending from the toes about half-way to the ankle. This was very slight, however, and there was no other physical sign. The patient complained of a slight feeling of numbness, "as if the foot were asleep." Being thoroughly under the influence of the morphia, his pain was slight. I now informed the family that gangrene of the extremity was to be feared and expected. Subsequent events proved that my fears were well grounded, as there immediately supervened that peculiar pathological phenomenon, death of the extremity, followed by a wonderfully fine operation of nature, separation of the

dead from the living tissue, with a reparative process, entirely unlooked for in a patient so reduced in blood, and in one so saturated with the cancerous poison, as evidenced by the large malignant growth, with its accompanying manifestation of the cancerous cachexia. The condition being one of dry gangrene, I had nothing to do but to use the best tonic remedies, with supporting diet and opiates to control the intense pain. Commencing at the toes, the gangrene gradually extended upwards to within about three or four inches of the knee-joint, at which point the line of demarcation became visible about eighteen days after the first symptom of pain. This line extended quite around the leg. Above it, for a distance of about two inches, distinct coldness was perceptible. Before the first week had elapsed, the extremity was dark and cold half-way to the knee. Upon applying an antiseptic solution of carbolic acid a change in color gradually took place. From dark blue it gradually became a sort of dirty green. The toes became mummified and boggy, and the foot and leg swollen. Remarkably slight systemic disturbance followed these changes. The patient ate, and slept, and talks rationally of his disease, occasionally joking about it.

At this time Drs. Rockwell and Sherwood saw the case with me, and agreed that it was very doubtful that the patient would live long enough for nature to complete the process she had begun. How well he stood the terrible drain is shown in fig. 1, taken from a photograph made when the tissues were entirely amputated and the skin over the stump well formed. His pulse at this time was rarely over 100, his bowels were regular. He had occasionally, slight mental disturbance. His tongue was somewhat coated. These were about all of the constitutional symptoms. Having decided, with the advice of Drs. Sherwood and Rockwell to let nature take its course, I simply continued the general supporting plan of treatment, with pretty large doses of morphia to keep the patient comfortable. Certainly if nature, hampered with such a complication as existed in this case could complete the process necessary for the successful separation of this poor man's leg, her powers would be greatly elevated in our estimation. How well she performed her part is now plainly seen. We did not theorize much as to the cause of the gangrene. It is possible that an embolus was carried from the degenerated mass on the patient's face to the extremity and then lodged and obstructed the circulation. Or, diseases of the blood-vessels in the foot may

have obstructed the circulation. This, however, is pure speculation, and it is not the object of this report to discuss the cause of the gangrene, but simply to show how wonderfully nature may do her work, even when almost denied the elements necessary for it, and to lead to greater confidence in the ability of nature to throw off disease, and to place the physician in the position of an assistant and not that of the active healer. On Nov. 4th, the patient was evidently weaker, but still so strong as to cause surprise

about 100, and the heart's action was very feeble.

On Nov. 29th, the patient was not losing strength as rapidly as we had expected. He still sat up in bed, although with much effort. He was now taking about half a grain of morphia every two hours. About two weeks ago I called and found his abdomen terribly distended. Indeed, it seemed as though it would burst. Upon inquiry, I learned that his bowels had not moved for about eight days. Enemata of turpentine

to all. He had had a bad hemorrhage from the cancer very recently. The condition of the foot and leg was progressing; the greenish discoloration extended over the whole foot and ankle. The leg, two-thirds of the way to the knee was almost black. The line of demarcation was now visible at the point before indicated. When the effect of the morphia wore off a little, he experienced intense pain, almost as bad as when I first visited him. The leg above the line was swollen, and quite tender upon pressure. The pulse was

and castor oil were given, and the bowels moved freely, much gas passing off and the distension rapidly subsided. He took liquid food almost exclusively. During the last week the ulcerating line had commenced to separate the dead from the living tissues. Below the line the leg and foot were dry and hard.

The line of demarcation described an irregular circle around the thickest part of the calf of the leg, and in a general way seemed to be a sort of a dropping away

of the dead tissue from the living and the leg was about half an inch smaller at the line of the dead tissue than at that of the living. The leg and foot were black, and hard, and dry, the skin imparting to the touch a sensation of extreme thickness. There was an opening on the outer side of the line of demarcation which seemed to open into a cavity, as large quantities of thick pus discharged through it.

The cancer on his face caused the patient much pain, with frequent hemorrhages. The odor from the face and leg was almost unbearable, and with difficulty kept down by the best of disinfectants.

At this time, May 20th, the patient is in the condition indicated in the illustration, which is from a photograph taken this day; the amputation is complete, with the exception of the bones of the leg, and they are beginning to separate. In a few days, the foot and leg will probably drop off. As shown in the illustration, the stump above is perfect, nicely skinned over, and to all purposes as fine as any made by a surgeon.

A very interesting point in the case is the fact that, the bones are separating about half an inch above where the skin comes down to them, nature thus providing plenty of skin to cover them.

To recapitulate: we have a patient 60 years old, who had suffered for two and a half years from a malignant cancer of the face, and had been brought down to a weak, anemic condition by severe and frequent hemorrhages. Suddenly attacked with senile gangrene, he yet bids fair to live through the whole operation of nature's amputation of the foot and leg. At this time, May 20th, as is shown by the illustration, he has nearly got through with the gangrene, and were it not for the cancer he might live to a good old age.

Let us therefore in future, place more confidence in the power of nature to help us out in such terrible conditions, when other help seems of no avail. And let us realize more fully that, in all pathological conditions, nature is the chief healer, and we are her assistants.

[A telegram kindly sent by Dr. Hollister, in response to a query, and dated June 28, 1886, states that this patient is holding his own. The slough has separated. He eats well, and temperature is normal. Pulse, 100. Stump and skin healthy.—EDITORS OF THE REPORTER.]

BICHLORIDE OF METHYLENE—AN ANÆSTHETIC.

BY LAWRENCE TURNBULL, M. D., PH. G., PHILA.

PREPARATION.*—By acting on chloroform with nascent hydrogen.

CHARACTERS.—A colorless, volatile liquid with smell like chloroform.

Methylene or bichloride of methylene was carefully studied by Dr. Richardson, who gave it a very high character as an anæsthetic. This was 1867. His views were soon called in question by Nussbaum in Germany, and Tourdes, Hept and Péan in France, while Spencer Wells took up the subject and defended it in England. For years it was fully tested at Moorfield Ophthalmic Hospital; but two deaths occurred without any indication of danger from the state of the pulse or heart. In 1879 I had it prepared by Dr. W. H. Green, and even with all his care the specimen contained chloroform, and was very costly. It was then tested by the late Dr. Washington Atlee, the article having been obtained through Spencer Wells; but Atlee did not find it as satisfactory in ovariectomy as his mixture of ether and chloroform. *Op. cit. infra.*, p. 130. Subsequently four more deaths occurred from its use.† Spencer Wells stated at the meeting of the British Medical Association, 1877: "Whatever may be its chemical composition, whether it is chloroform mixed with some spirit or ether, or whether it is really bichloride of methylene, I am still content with the effects of the liquid sold under that name." It is, I believe, still employed in the "Samaritan Free Hospital" of London by the officers in charge; but Spencer Wells has retired from the institution where he achieved such wonderful results. The operation of ovariectomy has been improved upon by Mr. Lawson Tait, under the use of ether, namely, one hundred and thirty-nine consecutive operations without a single death. Four years ago, M. M. Regnaud et Villejeau (*Journ. de Pharm. et de Chem.*, 1883) undertook a research which has recently been completed, and which led them to the following results: that the commercial

* $\text{CHCl}_3 \times \text{H}_2 = \text{CH}_2\text{Cl}_2 \times \text{HCl}$.

Boiling-point, 40°C . (104°F .).

ACTION.—Like that of chloroform, but more rapid, though a larger quantity is required. It depresses the action of the heart more than chloroform, and death is even more sudden and without warning symptoms.

† See list of deaths, with details. *Turnbull's Manual of Anæsthetic Agents*, 2d Ed., p. 66, Phila., 1885.

methylene, obtained through agents accredited by Sir Spencer Wells, and therefore genuine, was a mechanical mixture composed of four parts of chloroform and one of methylic alcohol. In some comparative experiments they administered the two agents, finding that while the commercial agent behaved precisely like chloroform, the genuine methylene bichloride produced choreiform and epileptiform convulsions.

HOSPITAL NOTE.

TREATMENT OF INFANTILE HYDROCELE.

Reported by J. T. Freeland, M. D., Assistant Surgeon of Hospital for Ruptured and Crippled.

In looking over the records of this institution, I found that one thousand one hundred and fifty-seven cases of infantile hydrocele have been treated here in the dispensary department. The treatment of this class of cases has varied at different times; but I notice that the change in treatment has been from the severe (*i. e.*, setons, iodine-injections, drawing out through an incision and snipping off a bit of tunica vaginalis) to the mild, and the results are now as good as they have ever been.

We first prescribe

Tr. bellad.

Tr. iodinæ co. āā ʒj.

M. sig.—Apply over hydrocele twice daily.

This is generally sufficient to relieve within a week or two, especially so if the infant is but a few weeks old.

If this fails to cause absorption after a fair trial, the fluid is drawn off by a hypodermic needle or a small trocar. It may be necessary to draw the fluid a second time, rarely a third; as the fluid does not show the tendency to reaccumulate in children as in adults. This last point is an important one, and should have much to do in changing the treatment generally employed by physicians.

The treatment given is applicable to all the forms of hydrocele, congenital, acquired, diffuse and encysted of the cord.

REPORTS OF SOCIETIES.

NEW HAMPSHIRE MEDICAL SOCIETY.

NINETY-SEVENTH ANNUAL MEETING, HELD IN
THE CITY OF CONCORD, N. H.,
JUNE 21, 22, 1887.

Tuesday, June 21—Morning Session.

The society was called to order at 11 o'clock by the president, Carlton P. Frost,

M. D., of Hanover.

The attendance was large, for, with a membership of two hundred and fifty, over fifty per cent. were present. That the profession in New Hampshire are interested in any legitimate means to elevate the standard of medicine, was illustrated by the number of new members received into the association—twenty—as well as by the prompt instructions to the Board of Censors to take peremptory measures to revoke a license which had been secured during the year on a diploma from a fraudulent university.

The first paper upon the programme was the President's address, in which he welcomed the members to the ninety-seventh annual meeting, and referred briefly to its objects and aims, and made suggestions as to some changes in the manner of doing its work.

He referred in fitting terms to members and ex-presidents who had died during the year—Dr. Luther M. Knight of Franklin, and Dr. A. H. Crosby, of this city, as follows: "Dr. L. M. Knight, a man whose warm heart and genial ways had endeared him to all who knew him, has passed away, after reaching the ordinary limit of human life. He has left an honorable record as a physician, as a surgeon in the service of his country, as a good citizen, and a Christian gentleman." "Dr. A. H. Crosby always ready with a pleasant word and a cordial greeting, ever seeking to promote the interests of those who came to him for professional council or aid in any emergency, was suddenly called away in the prime of professional life and influence. Highly esteemed as a surgeon by inheritance and by his scientific attainments and skill receiving the confidence of his patrons who were many and widely scattered over the state, he honourably closes for the present at least, the list of distinguished teachers and practitioners in his branch of a family whose names will be long remembered in this state and in this country."

The theme of the address was, The Etiology of Diseases, and in introducing the subject Dr. Frost said: The most recent theory in regard to the causation of disease, at least the theory whose study and elucidation have occupied the very careful attention of the investigators in the field of medicine, and has led to the most satisfactory results in many respects, is the germ theory, or the theory which rests on the belief that many diseases are caused by the introduction into the body, from without, of certain minute organisms whose development and reproduc-

tion cause such changes in the fluids and solids of the body that their normal vital actions are dangerously interfered with." The steps by which this theory has established itself in so many minds as worthy of acceptance were traced briefly and skillfully. The address received close attention and hearty applause.

The next paper on the programme was "Obstetrics: Thirty Years' Experience in a Country Practice," by Dr. William Child, of New Hampton. Dr. Child in this paper urged that a frequent reviewing of what may seem familiar points in obstetrical practice tended to proficiency therein. Personal experience, showing how many cases progressed rapidly and ended kindly without any aid, and the few that did require real skill, was given. Forceps were declared to be, first, the mother's instrument, then, second, the child's. Attention was called to the fatality in footling cases, and it was stated that this might be avoided by at once extending body of child between the knees of the mother to and upon the abdomen; decided traction being used if necessary; delivery of head will thus be ensured without delay. Attempts to deliver by extension in the line of the mother's body was condemned; with this method many children die.

In abortion with hemorrhage, the tampon was recommended as the only real remedy; this is to be of a continuous strip of fine cotton, one and a half inches wide, well oiled and then closely packed into the vagina; should be of one strip for convenience of introduction and removal. He had no new procedure to recommend but the utmost vigilance was urged in all uterine hemorrhages; more injury being done by indifference than by real want of skill. He recommended that ether and chloroform be employed only in obstetrical operations, or in very severe and painful labors. Some cases of puerperal convulsions were related. Treatment recommended as each particular case might demand. Bleeding in plethora; opium in spinal or cerebral anemia; active cathartics in apoplectic indications, chloral and bromide of potassium in general nervous excitability. If convulsion persists, deliver with forceps as soon as relaxation of soft parts will allow. Placenta previa cases demand the greatest courage, promptness and judgment to attain the best possible successful treatment. Obstetricians should never leave such cases for a moment until the danger is over. Caution and boldness are the only remedies when once the diagnosis is settled. More cases are lost from want of decision and

promptness of action than from real want of skill.

Dr. J. W. Parsons, of Portsmouth, opened the discussion by disclaiming any new or unusual methods, and in reference to the doctor's early experience said he believed a frank confession of almost all obstetricians in their early cases would be much the same as that of the country practitioner. He emphasized the rules given by Dr. Child and complimented him upon his almost uniform success.

Afternoon Session.

Dr. C. A. Morse gave an account of an epidemic of diphtheria in Newmarket in 1885 and 1886, in which there were one hundred and twenty-three cases treated, with a mortality of twenty-seven. There was one case of a child less than one year of age and one of a woman forty-four years old, but a large proportion were between the ages of four and twelve. In this it did not vary from the experience in other places. The writer claimed with considerable reason, that the epidemic originated or was developed in a primary school building, as the first case was taken ill while at school and during the time the school was open, twenty-nine out of the whole number of forty-seven, including one teacher, were taken ill; and with a mortality of sixteen, or more than fifty per cent. of those taken ill. The school was closed, the building thoroughly disinfected and there has been no trouble since. That the epidemic was very severe was shown by the great variety of secondary symptoms, as almost every form of paralysis was described as following the active symptoms. The discussion was opened by Dr. G. P. Conn, of Concord, who, in reviewing the paper, said, that in diphtheria as in all zymotic diseases, the physician would do more good to the community in the prevention than in the cure of such diseases; for when the epidemic gets a foothold, a certain number of deaths will follow before the cause of the trouble is eradicated and that it always proves embarrassing and discouraging to the physician to have the same influence which caused the disease depressing the vital powers of the patient and thus handicapping every means he could use to restore the child to health. The satisfaction a physician derives in the practice of medicine is destroyed unless he can feel that his efforts are to be rewarded in saving life; and when the well are made sick and those ill are made worse because waste and effete materials are left to decompose, thereby rendering the earth, air, and water contaminated, it is

no wonder the physician becomes disheartened and discouraged. It is gratifying to the profession and to the public to know that the epidemic described resulted in an increased effort on the part of the authorities of the town of Newmarket to effect a sanitary reform in their village.

Laceration of the Perineum.

The paper of Dr. F. B. Perkins, of Londonderry, on Laceration of the Perineum, gave as the most prominent causes:—rapid deliveries, large foetal heads and faulty mode of supporting the perineum. Too much discredit, he said, was cast upon the forceps as a cause of rupture. Danger from this source arises from the fact that they are as instruments of direct traction, instead of instruments to complete a normal process.

The following summary of preventive methods was given:

1. Pressure upon foetal head to prevent rapid descent. Avoid use of ergot. Dissuade patient from making voluntary effort, place patient on left side.

2. Administer chloroform or ether to relax vulva and perineum, anoint liberally with belladonna, perform episiotomy. Draw forward with the hand the perineum and anus, or the perineum alone by hooking the fingers in the anus (Goodell's plan). Hook the fingers in the posterior commissure and draw backward toward the coccyx with each pain. Judicious use of forceps an efficient means of prevention. Ocular examination of parts after delivery. Immediate operations for repair.

Dr. C. S. Whittier of Portsmouth opened the discussion, and in the course of his remarks, gave a full and clear description of the most approved method of operation for the restoration of a complete laceration and quoted from the recent edition of Drs. Goodell and Emmet in support of his position.

The Report on Therapeutics.

The report on Therapeutics, by Dr. L. C. Pattee, of Manchester, was long and historical in character. In the discussion that followed, the new remedies for reducing temperature, antipyrine and antifebrine received a share of attention, and the gentlemen discussing their merits were divided in their opinions as to the merits of these drugs. The same was true in regard to their efficiency in cases of pain. Nothing was said by anyone about the use of sulphuretted hydrogen and carbon dioxide in the treatment of phthisis; therefore we are unable to throw any light upon the dispute between the physicians of Baltimore and Chicago, whether

the gas, in theory, should be more fatal to the microbe or patient.

The Report on Surgery.

The Report of Surgery, by Dr. J. Cutler, of Peterborough, consisted of a report on four cases of abdominal section for the relief of ovarion disease, one of which was a cystic uninocular tumor and the second was a multilocular, and were successful. The other two cases, being complicated by the malignant nature of the tumor, died in a short time after the operations. The reporter drew the following conclusions in regard to these four cases;—Cases Nos. 1 and 2 were simply uni- and multiocular ovariectomies. The diagnoses were correct, the operations successful, and the recoveries as complete as the ages and general health of the patients would admit of. Case No. 3 was complicated with cancer, and the question arises as to the abandonment of the case without completion. The reports of Brown, Wells, Fox, Peaslee, Kimball, and Thomas all quite fully sustain the ground of a complete operation in cancerous complications. In case No. 4, the circumstances appear to fully justify a complete operation, and the best interests of the patient and those interested would appear to have demanded a much earlier one.

The remaining portion of the report consisted of a review of fourteen cases of hernia. The first three required an operation before reduction could be accomplished, with two deaths and one recovery. The fourth case was reduced under ether, while the fifth was operated upon and recovered only to have a recurrence five years later, when the patient refused to have a surgeon's aid and died in three days, fulfilling his threat, "that the doctors should never touch him again." Of the remaining eight cases, only one required an operation to effect a reduction of the tumor, and this one died the third day; the others were relieved without resorting to an operation. The inference to be drawn from these cases is that the patients and friends naturally shrink from the knife and that earlier operations would probably have been more successful.

The Confidence of the Public in Non-Professional Prescriptions.

The dissertation on "The Confidence of the Public in Non-Professional Prescriptions" elicited the fact that non-professional prescribing was much the same in New Hampshire as in other parts of the country, and that the neighbors and friends of the sick did not feel that they had done their duty

unless they gave a great deal of advice and a prescription for every conceivable ailment. The speaker drew some vivid pictures of the evils of such confidence and cited many cases of irreparable injuries in consequence of the neglect of more rational and intelligent treatment. The paper had many good points and would make a good medical tract for the public to read, for it is too true that the public are quite too much given to self-medication in the way of newspaper prescriptions and neighborly advice.

Morning Session, June 22.

The Society came to order at 8 A. M., and the reports to delegates to other societies and of the secretaries of district societies occupied the time until 9 o'clock, when the following officers were elected:

President—Dr. S. W. Roberts, Wakefield.

Vice-President—Dr. S. C. Whittier, Portsmouth.

Treasurer—Dr. D. Adams, Manchester.

Secretary, Dr. G. P. Conn, Concord.

Executive Committee: Drs. C. R. Walker, Concord; Geo. D. Towne, Manchester; John R. Kimball, Suncook.

Anniversary Chairman—Prof. Wm. T. Smith, Hanover.

A Council of twenty members and a Board of Censors of ten members complete the organization for the coming year.

A good programme was submitted by the Executive Committee for the next annual meeting; and the remaining part of the session was occupied in miscellaneous business and in the report of cases that had occurred in the practice of the members. This proved to be interesting and instructive, for in thus comparing notes, many a member received and imparted new ideas in the management of rare and difficult cases. The meeting was entirely harmonious in its views and the profession are apparently thoroughly alive to the importance of a high standard in medical work. The committee on the History of Medicine and Medical Societies in the State have already accomplished a great deal in their work, and it is safe to predict that when the centennial is celebrated in 1890, the profession of the State will have a full and accurate history to submit to the world that will be an honor to the State and the country.

AMERICAN ORTHOPÆDIC ASSOCIATION.

[Continued from p. 820, REPORTER, June 25, 1887.]

DR. RIDLON, of New York, was convinced that in a number of cases of chronic osteitis

about the joints, recovery would take place under the thorough use of mercury. He related one case, that of a girl whom he treated about two years for ankle joint disease, and when she had about recovered of that disease, it appeared at the shoulder joint. He became convinced that hereditary syphilis had something to do with it, and rubbed in blue ointment, and eight months later the shoulder which had been immovable, and to some extent atrophied, admitted of considerable motion.

Notes on a Case of Pott's Disease.

DR. H. L. TAYLOR, of New York, related a case of Pott's disease, the interesting points in which were, extreme lateral distortion at two points, and prompt rectification by giving antero-posterior support.

Remarks upon the case relating to the question of diagnosis of Pott's disease at a time when marked lateral deformity was the principal symptom, and to the marked benefit derived from an antero-posterior support, where made by Dr. Ridlon, Dr. Ketch, Dr. Shaffer, Dr. Stillman and Dr. Hodgson.

Ischiatic Crutch.

Dr. Judson, of New York, presented an inexpensive ischiatic crutch, for use in case of disease of the knee or ankle joint, or conditions in which otherwise an auxilliary crutch would be required.

Remarks on the advantages of the instrument were made by Dr. Gibney, Dr. Roberts and others.

On Uniting the Tibia and Femur in Excision of the Knee.

DR. MORTON, of Philadelphia, made some remarks upon the use of a strong catgut ligature for tying together the femur and tibia in excision of the knee. He had employed this method in several cases, and had found that union resulted much more quickly than when the limb was put up simply in a fracture box or plaster-of-paris dressing. The surfaces were much more closely approximated, favoring early union. And to hold the joint firmly, it was necessary only to apply a posterior splint fairly molded, and a bandage. Pain, delayed union, suppuration and high temperature, which often attended excision of the knee joint, were avoided by this method.

This principle of fastening together bones which it was desired should unite, he had applied to fracture of the patella. Three or four days after the fracture, he drilled holes through the separated pieces and drew them together by means of catgut: no other treat-

ment was necessary. In this connection Dr. Morton made some remarks upon one cause of non-union in fracture of the patella, namely, the intervention between the bony surfaces of fragments of the tendon.

DR. SHAFFER referred to a case in which, some time after excision of the knee was performed, increasing deformity at that joint took place. It was difficult to decide whether there had been imperfect coaptation of the parts or whether some of the diseased tissue had been left. Careful examination revealed slight motion in the joint.

Thursday, June 16, 2.30 P. M.

Plantar Spring for Flat Foot.

DR. A. S. ROBERTS, of Philadelphia, presented a plantar spring for use in flat foot. He spoke of the frequency of spurious valgus or flat-foot, the pain and debility resulting from it, and the liability of the deformity to be mistaken for rheumatism, neuralgia, or even tarsal osteitis. He described the bony arches of the foot, and the part the second or supplementary one played in support of the superincumbent body weight, together with the changed relations of these parts in the acts of walking, running, dancing, etc. The relation of vessels, ligaments and fasciæ as accessory supports were also described at some length; the weak point of the arch was located where the astragalus rested upon the os calcis, and that in occupations requiring continued standing and walking, the muscular and ligamentous supports of the arch became overtaxed and did not afford proper assistance to the bony arch, as a result of which permanent extension or flattening of the foot resulted.

In speaking of the morbid anatomy, the author stated that in the congenital variety the flattening of the arch, which is incomplete at this period of life, is more apparent than real, owing to the associated valgus which is always present in these somewhat rare conditions. The causes of the acquired varieties were stated to be rachitis, infantile spinal paralysis, rheumatism, and tarsal or ankle-joint osteitis. Bow-legs and knock-knee produce flat-foot symptomatically. These cases generally occur, the speaker went on to say, in adolescence and in those whose occupation compels them to occupy the standing position for a long time. Their gait is characteristic, heavy and dragging; the knee is bent, while the feet are placed gingerly on the ground. In speaking of treatment, special attention was given to the so-called inflammatory form, the speaker

stating that rest, which is essential, could best be attained by the use of tempered steel springs, so made that the convexity of the spring should be at that point where the arch of the foot is most flattened. A great improvement over the narrow spring which was let into the shank of the shoe, had been suggested by Mr. Arthur Lea, in which the spring was much broader, longer, and in addition to supporting the arch of the foot, prevented internal rotation by the extension upwards of flanges from the main body of the spring. Dr. Roberts stated that he had made use of the tempered steel springs in upwards of forty cases, with the most gratifying results in the relief of pain, disability, etc., finding them more convenient than the older forms of plantar support and ankle braces.

DR. KETCH had used this instrument, and said that one advantage which it possessed over similar instruments was that it could be taken out of one shoe and readily placed in another.

DR. SHAFFER, of New York, had noticed in a number of cases of flat-foot, or non-deforming club-foot, that there was shortening of the gastrocnemius muscle, and it had been a question in his mind whether this shortening had occurred first, or whether it followed the giving way of the plantar arch. He was disposed to think that this shortening of the gastrocnemius, lifting the os calcis from the ground, assisted in the development of flat-foot, for the weight was thrown upon the metatarsus. There was increased antero-posterior mobility at the metatarsal joint and limited motion of the os calcis in a direction downward and forward. He thought that recovery was much enhanced by division of the tendo-Achillis.

DR. L. H. SAYRE related a case seeming to support Dr. Shaffer's view, and Dr. Stillman described his method of treatment of flat-foot, which seemed also to owe its advantages partly to the fact that during the treatment, tension was made upon the gastrocnemius.

DR. ROBERTS had seen a considerable number of cases of flat-foot, but in none had he observed marked shortening of the tendo-achillis. Nor was this deformity of the plantar arch encouraged by the abominable fashion among ladies of wearing high heels, which tended to shorten the tendon.

DR. GIBNEY remembered having read an article in the *Lancet*, in which the writer advocated raising the heel for the cure of flat-foot, and said that ballet dancers, who had shortening of the gastrocnemii, had

anything else than flat-foot. Dr. Gibney had had one or two young lady patients study the ballet somewhat, and they had not been under the necessity of wearing the spring for flat-foot.

Hip-Joint Disease.

DR. BRADFORD, of Boston, gave the abstract of a paper containing the history of a case of hip-joint disease. The patient had been considered well for six years, the only evidence of the old disease being ankylosis of the joint. He then died of tetanus, and at the autopsy they were surprised to find caries of the acetabulum and an abscess in the pelvis. There was a small sequestrum on the head of the femur. But the head had become solidified and was strong, so that the patient had been able to walk about well with a stiff joint.

Excision of the Hip-Joint.

DR. L. H. SAYRE related the history of a case of hip-joint disease in a boy twelve years of age, who, two years before he excised the joint, had consulted Dr. H. L. Taylor for supposed disease of the hip-joint. Dr. Sayre operated in February last, first making an exploratory incision over a fluctuating tumour in the gluteal region. He thought the abscess was connected with disease of the ilium and that the joint was not implicated. The difficulty in diagnosis was not cleared up after evacuating the pus until, by manipulation, gella tiniform material exuded, which he regarded as evidence of implication of the joint. Disease of the femur and acetabulum was found and excision was performed. He thought the case was in line with that presented by Dr. Bradford, going to show that hip-joint disease might be present a long time after an apparent cure. The patient had done well since the operation. It was to be noticed that the sister of the boy thought he had always walked as if he had a wooden leg.

DR. SHAEFFER thought that the propriety of resorting to excision in disease of the hip-joint in cases presumably calling for it, was less evident than in disease of the knee-joint and other joints, where excision was really practicable. Scraping of the acetabulum was not really excision.

DR. BRADFORD said that it was not customary to perform complete excision of the hip-joint in this country, but that he had seen it done in Europe.

The Missing Link.

DR. GIBNEY presented a specimen received from Dr. Morgan Vance, consisting of an outgrowth from the integument over the

lower sacral region, four or five inches long, removed from a mulatto child.

DR. RIDLON recited the history of two cases, which during the first months pointed to disease of the vertebra in the cervical region, although no knuckle had yet appeared; but after eight months' treatment in one case, and five months' treatment in the other, the error in locating the disease became apparent. The vertebræ really affected were the first dorsal.

DR. KETCH referred to similar cases.

Psoas Abscess.

DR. BRADFORD gave the histories of five cases, in which he performed Koenig's operation, cutting down and evacuating gaseous matter and fragments of sequestra. All of his patients did well. When there was a large abscess which could not be absorbed, he thought an incision should be made, and the abscess drained thoroughly. He related a case of double iliac abscess so treated.

DR. HOGDEN, of St. Louis, recited five cases of psoas abscess consequent on caries of the spine, treated by aspiration of the abscess. The object of his remarks being to get the opinion of the members on the propriety of such treatment, which, although not new, had not, he thought, received the attention it should. The three methods of treating such abscesses were, the expectant, the operative with drainage and aspiration as soon as the diagnosis of Pott's disease could be made and the presence of pus detected.

The objections to allowing the abscess to take care of itself might be summed up under three heads, namely: there was destruction of tissue, there was interference with function, and there was inconvenience, if not pain, to the patient. The uncertainty of where the abscess would burrow was also an objection to the expectant plan; it might burrow under Poupart's ligament, or point in the gluteal region and do no harm. Yet it might enter the bladder or intestine. In one of his cases he believed it had opened into the hip joint of the same side. In each of his five cases the result after from two to five aspirations had been good. No evidence was left of there ever having been psoas abscess. He did not think that any one would claim that this treatment led to absolute cure, but he did hold that after aspiration of the abscess it might end there; still it might not. He would not aspirate oftener than four or five, or seven times. After that he would put on the plaster-of-paris jacket and let the abscess alone.

DR. SHAFFER, of New York, said that Dr. Hodgen's results with aspiration of psoas abscesses had been much better than his own. In many cases he had found that although there was evidently plenty of pus present, numerous aspirations resulted in the withdrawal of but a small quantity. With regard to the danger of the abscess opening into the bladder or rectum, he had seen several such cases, and if he could have his choice he would always have his abscess open into the rectum. A valvular opening formed, and bad results had not followed. He also had seen several cases in which the abscess had opened into the bladder without serious results.

DR. RIDLON thought that although one or two or even fifteen cases might have occurred in which the abscess following a few aspirations had dried up, it did not prove that aspiration would cure a discharge connected with diseased bone. He had had an extensive experience with such abscesses, and he had repeatedly seen large abscesses dry up without any known cause. He believed in letting the abscesses alone. The fact that they might dry up after aspiration did not prove that aspiration was the cause of it.

DR. KETCH said that Dr. Ridlon's remarks were in accord with those of the orthopædic surgeons of New York during a discussion on the treatment of abscess connected with hip-joint disease recently. The two conditions were similar, and the orthopædists then generally held that the non-interference plan was the best. On the contrary, the general surgeons present advocated active procedures. What had struck Dr. Ketch was the fact that patients with abscess connected with joint or spine disease did much better when wearing a comprehensive support than without; the abscess seemed to pursue a much more benign course.

Improved instruments were presented by Drs. Taylor, Ketch, Stillman and Knickerbocker.

Osteoclasis.

DR. DILLON BROWN presented a lad on whom he had performed osteoclasis. There was a very marked anterior curve which some surgeons thought made the osteoclast inapplicable. This was the only case out of a series of fifteen in which there had been any return of the deformity, although they were put up in plaster for only six weeks, and then allowed to go without a support. Photographs were presented.

Torticollis Due to an Anomaly of Vision.

DR. BRADFORD related the case of a boy twelve years of age, referred to him on ac-

count of supposed torticollis. On examination he found none of the muscles contracted, and no apparent reason for carrying the head on one side. It was found that in order to secure binocular vision the boy had to turn his head to one side in the position of one having torticollis. The oculist to whom he had sent the patient thought he would be able to cure him.

After the election of officers (see REPORTER, June 25, p. 823), the association adjourned. The time and place of meeting in 1888, was left with the executive committee.

TENTH ANNUAL SESSION PENNSYLVANIA PHARMACEUTICAL ASSOCIATION, PHILADELPHIA.

The Pennsylvania Pharmaceutical Association began its tenth annual meeting in Philadelphia, June 14. The Association is composed of all the principal pharmacists in Pennsylvania, and has a large membership.

President Myers, in his annual address, after reviewing the events of the year, referred to many changes in pharmaceutical preparations during the past year. He referred to the passage of the Pharmacy law in this State, and alluded to the fact that the thanks of the association were due to the members of the Legislature who aided and voted for the passage of the bill in the face of determined opposition. Speaking of the the new Pharmacy law, he said: "It is probably not all that could be desired or hoped for. Many people seem to have entertained the idea that this law was something got up solely to put money into the pockets of the druggists at the expense of the people. It will take time to educate them to the contrary, but when the true worth of the bill is once understood, all this prejudice will be put away, and at the proper time such amendments tending to perfect it as may be necessary, can easily be obtained."

"The High License Bill," the President, said, "to some may come as a sore affliction; but to the honest, legitimate pharmacist, aside from the fact that it will entail some additional labor, it must present itself as a thing much to be desired. It defines the status of a druggist before the law, who, in the pursuance of his legitimate calling, must dispense a limited amount of intoxicating liquor for medicinal purposes. It is to be hoped another and greater good may emanate from this new license law. We all know, and to the disgrace of true pharmacists, that in many localities the drug store and the rum shop were practically one and the same; or, in other words, in very many

drug stores the sales of liquors for beverages, either at the popular soda fountain, under high sounding names of fancy syrups, or straight and unmixed, made up a very large portion of the daily incomes of these stores. Men are to-day pursuing the liquor traffic as pharmacists who would be ashamed to hang out the sign of retail liquor dealer, which more nearly represents their true calling.

"Passing along one of the principal streets of this city not many months ago, my attention was attracted to the show-window of one of the old pharmacists of Philadelphia by a large display of 'Vinous Rubber Grapes,' hung in clusters, packed in boxes, and otherwise offered as a prominent attraction to passers-by. Brandy, gin, whiskey, and what not else, unblushingly exposed for sale in form 'convenient for a drink' by a pharmacist who deems himself reputable and law-abiding. Nor much better, if any, is the pharmaceutical journal which gives prominence to the advertisements of the "Vinous Rubber Grapes," and near by that of the "Book Phlask," another form of disguising the sale of—to the unlicensed—unlawful goods; and to these might be added the jobber who places them in the retail trade for the manufacturers."

The President also suggested a closer relation between the medical and pharmaceutical associations, and recommended an exchange of delegates between the State Pharmaceutical and State Medical Societies. He condemned "the growing tendency among some pharmacists towards speculative purchase of leading drugs," notably opium. "This," the President said, "is gambling, pure and simple, and leads but to certain disaster in the end."

I. H. Redsecker, Chairman of the Committee on Legislation, related the experience of his committee in having the Pharmacy bill passed at the last session of the Legislature. Great opposition, he claimed, came from the thirteen doctors, who were members of the House. The bill, he said, was not just what the committee desired, but it was the best obtainable.

Professor Remington said the law places pharmacy in a humiliating position from the fact that a physician with three years' experience can practice pharmacy without an examination, while graduates in colleges of pharmacy of acknowledged reputation are required to pass an examination. He thought the association should record the fact that it deprecates Section 11 of the bill. It is not, he said, that graduates of any college of pharmacy will be afraid of examination by

the State Board before practising their profession, but because pharmaceutical education is ignored and the diplomas of graduates of medical colleges recognized.

Noeggerath on the Results of Gonorrhœa.

(1) "Gonorrhœa in the man, as well as in the woman, persists for the whole life-time, in spite of apparent cure.

(2) "There is a latent gonorrhœa in the man as well as in the woman.

(3) "Latent gonorrhœa in the man as well as in the woman may evoke in a hitherto healthy individual either a latent gonorrhœa or the symptoms of an acute attack.

(4) "Latent gonorrhœa in the woman manifests itself in course of time by perimetritis, acute, chronic, or recurring, or by ovaritis, or as a catarrh of some definite portions of the genital mucous membrane.

(5) "The wives of men who at any time of their lives have had gonorrhœa, are, as a rule, sterile.

(6) "Such women, if they do become pregnant, either abort or bear only one child. Exceptionally three or four children are born.

(7) "From the discharge of a woman affected with latent gonorrhœa, a fungus may be cultivated, which is exactly analogous to that obtained from the discharge of acute gonorrhœa in the man.

"I am only too conscious that not fifty, but five hundred and more observations, and much more extended experiments, are required to impress upon the propositions the stamp of established thesis. I present them simply as the results of my individual investigations."

On the subject of sterility as a consequence of latent gonorrhœa, Noeggerath carries his conclusions further than the evidence produced seems to justify. He maintains that gonorrhœa is a common cause of sterility in the man, producing azoospermia, and he gives cases in proof. He is more convincing in dealing with the analogous effect on women, and he makes out a better case, though here also he leaves an impression of going beyond the record.

Noeggerath never hints at operative treatment, except to condemn it, but it is probable that few chapters have ever been written in more eloquent and telling support of the surgical treatment of this class of ailments than the portion of this short work devoted to treatment. DR. SINCLAIR in *Manchester Medical Chronicle*, June, 1887.

EDITORIAL DEPARTMENT.

PERISCOPE.

Antipyrine and Antifebrine in Headache and Epilepsy.

In a paper on this subject, published in the *N. Y. Medical Journal*, May 28, 1887, Dr. Allan McLane Hamilton recalls the fact that in January last, Ungar related his experience with antipyrine in the treatment of hemicrania, and in March Dr. C. B. Lyman, who had been induced to try the remedy after the publication of Ungar's success, administered it in several cases of neuralgia of the cervical, facial, and supra-orbital or mixed varieties, with more or less benefit. The first of these observers experimented with it as a successor to the salicylates, which have proved to be of great value in his hands in several varieties of headache, and he witnessed no evil results from doses of even twenty-three grains. Lyman used an initial dose of fifteen grains, repeated two or three times if necessary, and relieved the paroxysms, but did not prevent their recurrence. In last March Dr. Hamilton began a trial of this drug, and afterward its successor, antifebrine, in a variety of headaches, in insomnia, and in epilepsy. Some of the cases had been treated with more or less success with the salicylate of sodium, and the usual remedies, and the case of epilepsy were under modified bromide or other treatment. The cases of headache were those of migraine of the angeo-spastic and angeo-paretic varieties, as well as ordinary facial or sub-occipital neuralgias; and the cases of epilepsy, which were those of the symptomatic form, complicated with objective and subjective indications of cerebral disease, as well as the simpler forms which seemed to be dependent upon continued states of cerebral ischæmia, cerebral instability, etc.

In angeo-spastic migraine with evidences of cutaneous anæmia, dilated pupils, and coldness, the headache commencing in the morning, he found both antipyrine and antifebrine would quickly abort the paroxysms after the first dose.

He has used both drugs in cases of habitual insomnia in doses varying from three to eight grains of antifebrine, and ten to twenty of antipyrine, without appreciable result. In a case of maniacal excitement, due to nervous exhaustion and connected with moderate rise of temperature (102° F.), fifteen grains of antipyrine, repeated

twice induced refreshing sleep and a subsidence of excitement. There can be no doubt that, in wakefulness due to general disease, especially with high temperature, the value of both these drugs as hypnotics is very great. It would seem as if both remedies were of value in headaches or cerebral states attended by anæmia, or in the excitement due to cell malnutrition and exhaustion; and, though antipyrine seems to be the more serviceable remedy, it possesses drawbacks which do not belong to antifebrine. It would appear as if both remedies were valueless, or even harmful, in cases of epilepsy, but worthy of a trial in light cases attended by general cerebral vascular spasm and not much muscular movement. In several cases of *petit mal* the good effect of continued doses of antipyrine and antifebrine is manifest; for the losses of consciousness are far less frequent than when the patients were under other treatment. So far as tolerance goes, Dr. Hamilton has given to one patient forty-five grains of antipyrine in two hours without ill effects.

Poisoning by Pennyroyal.

Dr. J. Girling writes as follows to the *British Medical Journal* of June 4, 1887: The rarity of poisoning by pennyroyal, or oleum pulegii [hedeomæ, U. S. P.], is emphasized by the fact that standard works on toxicology, like Guy and Taylor, contain no account of the toxic symptoms produced by this drug, nor any indications as to appropriate treatment. Moreover, I find on inquiry that recurrence to pennyroyal is very common when menstruation has ceased suddenly, and that it can be procured with the utmost facility. These considerations have led me to describe the symptoms and the treatment employed in the following case. About an hour after the drug had been taken I found the patient (a woman, aged 40) in an extremely collapsed condition. The face was pale, cold, and bedewed with beaded sweat, and the hands and feet were cold and clammy. She lay apparently unconscious, but could at first be roused by shaking and shouting to her, rapidly sinking, however, into a state of profound coma. The pupils were normal in size, and responded to light. The action of the heart was exceedingly weak, irregular and fluttering, the pulse at the wrist being scarcely perceptible. The first cardiac sound

was almost inaudible, while there was distinct reduplication of the pulmonary second sound. There was jactitation and feeble retching, with much salivation, but no vomiting and no purging; temperature 97° F. The breath smelt very like peppermint. The treatment adopted was as follows: First, I gave her three-quarters of a tumblerful of water, followed immediately by a hypodermic injection containing one-fifth of a grain of apomorphine. This latter quickly produced the desired effect, the vomited matters having a strong peppermint-like odor. After the vomiting the patient seemed about to die, and having no ether with me I administered brandy hypodermically. The result of this was excellent; the heart-sounds at once began to improve in tone, and the pulse in force, and in twenty-four hours the patient was practically well. Thus the symptoms taken together seem to point to severe cardiac depression, approaching to paralysis, and appear to indicate that pennyroyal should be classed among the narcotic heart poisons. It transpired afterwards that the woman had taken $\frac{3}{4}$ of the essence of pennyroyal (which she had obtained from a chemist), and which is composed of of $\frac{3}{4}$ olei pulgeii to $\frac{3}{4}$ vii of spirit.

Prostitution and Insanity.

At the first (Moscow) congress of Russian alienists, Dr. Praskovia N. Tarnovskaia, of St. Petersburg, communicated (*Vratch*, No. 9, 1887, p. 216) the results of the anthropometric examination of fifty habitual prostitutes, who had all been inmates of brothels for a period of not less than two years. For the sake of comparison she examined in the same way fifty peasant women of the same age, and as far as possible of the same intellectual development, etc. The results of this—probably unique—investigation may be summed up as follows: 1. The prostitutes presented a shortening amount to half a centimetre, of the antero-posterior and transverse diameters of the skull. 2. As many as 84 per cent. of habitual prostitutes showed various signs of physical degeneration, such as irregularity in the shape of the skull, asymmetry of the face, anomalies of the hard palate, teeth, ears, etc. 3. In 82 per cent. of the prostitutes the parents were habitual drunkards. 4. In 18 per cent. of cases the prostitute examined was the last survivor of a large family of eight to thirteen children, all of whom had died at an early age. 5. These facts afford grounds for the belief that prostitutes, as a class, furnish the largest contingent of subjects predisposed to

nervous and mental affections. There is no special work in any language on this subject, nor are there any statistics as to the number of prostitutes yearly admitted to asylums. Dr. Tarnovskia urged the desirability of collecting such statistics for the purpose of determining the part which professional prostitution plays in the causation of mental and nervous disease.

Massage in Traumatic Orchitis and Epididymitis.

In the *Meditzinskoie Obozrenie*, No. 1, 1887, p. 41, Dr. Evgeny D. Kürduemoff, of the Moscow Military Hospital, says that he recently tried the massage treatment in three cases of orchitis and in two of epididymitis, all the patients being soldiers who had received some injury to the parts, in the course of gymnastic exercises, etc. Massage was resorted to, with the view of bringing about a resolution of the painful induration and enlargement, on the 7th, 11th, 14th and 15th day of the disease, after ordinary means had failed. The treatment was carried out once a day, and the number of sittings required varied from five to ten, each lasting from ten to twenty minutes. The manipulations consisted in alternate centripetal rubbing and kneading of the epididymis, testis, and hypogastric region. The results were most satisfactory. The swelling and induration seemed to "melt away under the hand." In every case the pain, tenderness, and feeling of weight diminished after the first sitting. In no case were any unpleasant secondary effects observed. Dr. Kürduemoff thinks that massage may also advantageously be tried in the initial stage of acute inflammation of the testicle, with the object of removing congestion, and promoting absorption of serous infiltration, as well as in plastic orchitis.

Resistance to Toxic Agents by the Fasting Individual.

At a recent meeting of the Paris Biological Society, M. Roger communicated a note on the effect of fasting on the power of the animal economy to resist the action of poisonous alkaloids. In a former paper he showed that the liver, when containing glycogen, was capable of arresting a part of the alkaloids passing through the organ into the system. When a 1 in 400 solution of sulpho vinate of quinine was injected into a peripheral vein of a rabbit in the proportion of 6 centigrammes to every kilogramme of the weight of the animal, it was found to produce a toxic effect, whereas a dose of 16

centigrammes to the kilogramme was required to produce death when the same substance was injected into a portal vein. When the animal had fasted for twenty-four hours a larger dose was required. If glucose be added to the solution injected, however, or, if three hours before the experiment, a certain quantity of sugar be given, the liver again becomes capable of arresting part of the alkaloid. The effect of neutral sulphate of atropine on rabbits which had been deprived of food for twenty-six hours showed that the animal resisted the poison better in the fasting than in the normal state. After five days of fasting, when the liver no longer contained glycogen, the organ was found incapable of arresting nicotine.

Green Stools of Infancy.

M. Hayem has recently presented before the *Académie de Médecine*, a paper upon the treatment of the green diarrhoea in early infancy and on the microbial nature of this affection. He at first undertook to combat the gastro-intestinal troubles of very young children by means of various treatments previously in use; of these hydrochloric acid gave the most permanent result. Lactic acid was found useful but of less efficiency. Finally, having observed that the admission to the *crèche* of an infant attacked with green diarrhoea was the signal for the appearance of similar evacuations among the infants in the same apartment, he reflected upon the possible contagion from these green stools, and instituted prophylactic measures against such contagion, this consisted in the speedy removal of the cloths soiled by the dejections and matter vomited, and these cloths were washed in a one per cent. solution of bichloride or mercury. Since this period the green diarrhoea has ceased to prevail in the *crèche* of the Hospital St. Antoine. M. Hayem and M. Lesage, his interne, have succeeded in proving that the green color of the stools was due to a special bacillus, the penetration of which into the system and the intestine may be recognized by the phenomena of green diarrhoea.

This observation is of great interest as explaining the good results of the internal administration of antiseptic remedies in these affections.

Expulsion of a Pin from the Lung, after Sixteen Years.—Acute Phthisis.

Dr. Colquhoun reports in the *Australian Medical Journal*, the case of E. W. A., æt. 21, suffering from acute phthisis in an ad-

vanced stage, and was much exhausted by a journey from the country. The right lung was dull from base to apex; the left apex had broken down, and there were the usual signs of acute general pulmonary tuberculosis. The other organs of the body were apparently unaffected. There was said to be no trace of phthisical history in her family, and I saw her father and mother subsequently, and found them to be strong and healthy. She had profuse expectoration, night sweats, cessation of menses, and rapid emaciation. The amount of expectoration continued very great, and on May 15, she coughed up three fragments of a pin—much eroded and very brittle. Her mother stated that she distinctly remembered that her daughter "swallowed a shawl pin when she was between the age of four and five years." Some days after spitting up the pin she died.

Syrup of Superphosphate of Iron and Oxygen.

DR. RICHARDSON, in *The Asclepiad*, No. 14, gives the following useful formula:

Syrup of superphosphate of iron, solution of peroxide of hydrogen (ten-volume strength), pure glycerine—of each a fluidounce. Mix. To make a mixture of three ounces. Dose for an adult, from one to two fluidrachms two or three times a day in three ounces of water.

It can be made to combine with tincture of nux vomica, with strychnine, and morphine, codeine, quinine, salicine, or any other agent which does not by its presence disturb or liberate the oxygen from the peroxide.

The syrup, as it is, is a most useful remedy in cases of a neurasthenic type, and especially when anæmia is also present. In an instance of pure anæmia treated with the syrup in combination with an occasional saline purgative, I have seen more rapid results toward recovery than from any ferruginous remedy I have hitherto employed under similar circumstances.

Therapeutic Scraps.

Terpin Hydrate has been found of value as an expectorant and diuretic.

Dr. J. G. Ellis has had good results from the internal use of stillingia in croup.

Apomorphine given in nauseating doses has been found, by Dr. C. L. Dana, to break up hysterical attacks.

Cannabin Tannate has given good results in the treatment of the agitation which precedes delirium tremens.

Gelsemine in one-two hundredth of a grain dose has been used with advantage in the treatment of yellow fever.

Succus Papaya rapidly dissolves the membrane of croup if a five per cent. solution be locally applied by means of a hair pencil.

British and Colonial Druggist states that twenty grains of a one per cent. strophanthin ointment rubbed into the arm reduces the pulse beats and cardiac pulsations.

Dr. A. F. Pattee (New York Medical Journal) has found antipyrin of great value in lung hæmorrhage, probably from the influence which antipyrin exerts over nervous agitation, a condition which accompanies and aggravates hæmorrhage of the lungs.

In a discussion at a meeting of the Medical Society of New York county, Dr. Fox stated that in some cases of baldness, local treatment sufficed to remove the abnormal condition of the scalp on which the alopecia depended. In other cases there was a good condition of the scalp, and baldness occurred in consequence of other causes, such as exhaustion of the nervous system, etc., and in those cases a general tonic and hygienic treatment might produce restoration of the hair or arrest its falling. Then there were cases of *inevitable* baldness, beginning as a small spot upon the vertex, or going up from the forehead, and in which the only thing which could be done was "to make the best of it." He doubted whether the style of hat had anything to do with causing baldness.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT LITERATURE.

—In Richard Ely's "Labor Movement in America," there is a statement which seems worthy of closer consideration from a medical standpoint: "The Shakers [who are celibates] live to be very old. There had been three deaths at Mt. Lebanon during the year previous to my visit; two brothers aged 87 and 91 respectively; one sister, 138. One of the sisters told me that the brother of 87 could in his last year run a race with any of the boys. She said also that his mental vigor was remarkable to the last. Daniel Fraser is between 80 and 90, and his intellectual powers seem entirely unimpaired. . . Among the Economites one may see men and women of 70 and 80 still hale and hearty."

—The twenty-second volume of the "Encyclopædia Britannica," completing the letter "S," is now ready. The principal literary

and scientific articles are, "The sonnet," by Mr. Theodore Watts; "Sophocles," by Professor Campbell; "Spanish Literature," by M. Morel Fatio, the first Spanish scholar in Europe; "Swedish Literature," by Mr. Gosse; "Syriac Literature," by Professor Wright; "Dean Stanley," by the present dean of Westminster; "Socrates," by H. Jackson; "Stoics," by D. Hicks; "Slavs," by Mr. Morfill; "Slavery," by Dr. Ingram; "Skeleton," by Prof. St. George Mivart; "Sponges," by Dr. Solias; "Steam-engine," by Professor Ewing; "Sun," by Mr. Lockyer; "Surface," by Professor Cayley; "Surgery," by Professor Chiene and three other contributors; "Spiritualism," by Mrs. Henry Sidgwick; and "Sword," by Prof. F. Pollock.

—The illustrations in Professor D. A. Sargent's article on "The Physical Proportions of the Typical Man," which appear in *Scribner's Magazine* for July, are from photographs of athletes, and diagrams furnished by the author. This article will be of special interest to young men engaged in outdoor sports and general athletics, and will also be of unusual value to teachers and parents as a guide to them in the physical development of their pupils and children.

BOOK NOTICES.

Stricture of the Urethra: its diagnosis and treatment facilitated by the use of new and simple instruments. By E. Distin-Maddick, F. R. C. S., Edin., etc. 8vo, pp. 154.

This book is evidently the work of a conscientious and pains-taking surgeon, who has studied his subject very carefully. It contains many valuable suggestions as to the treatment of strictures, especially by bougies or catheter. Again and again the author emphasizes the necessity for gentleness and delicacy in the manifestation required in these procedures, and points out the temptations to and the dangers of haste or roughness. In this we can heartily endorse his teaching. We can also recommend to our readers his views as to the importance of considering the constitutional state of patients suffering with stricture.

As to the "new instruments" referred to in the title, we cannot speak so positively, in view of the fact that they have not yet—so far as we know—reached this side of the Atlantic.

THE Medical and Surgical Reporter.

**A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.**

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium,	6.00
Physician's Daily Pocket Record,	1.50
Reporter and Pocket Record,	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The edition for this week is 10,000.

THE NEW VOLUME OF THE REPORTER.

With this issue the MEDICAL AND SURGICAL REPORTER begins its 57th volume. For 34 years it has been going to a very large number of subscribers, and it has come to be one of the best means of communication between the members of the medical profession in the United States and abroad.

On May 1st, of this year, the present editors assumed control of its management, determined to spare no pains to make it even a better medical journal than it has been in the past. They have already made certain improvements in its appearance and in the character of its contents, but the beginning of a new volume gives them an opportunity to do more.

The new volume is to be printed with entirely new and very legible type, on better paper than has heretofore been used, and with a wider and handsomer page.

The best writers in the country will contribute to its columns, and it will still present as its leading features the terse, practical observations of its practical

subscribers everywhere. Valuable hospital reports, condensed society reports, carefully prepared abstracts from other journals, brief notes and comments, and items of news, will keep our readers informed as to what is going on at home and abroad.

The novel feature of liberal cash payments for all published contributions to the Original Department will result in the advantage of all concerned.

The editors are strongly opposed to the fallacious policy of so-called "impersonal journalism." While they do not necessarily share the opinions of all their contributors, they hold themselves individually and jointly responsible for the *character* and *tone* of the journal from cover to cover.

The REPORTER is the exponent of no commercial interest. It is a *professional* journal in the strictest sense, and its editors look to their professional brethren for that support which is earned by a first-class journal conducted upon these principles.

THE MONUMENT TO BENJAMIN RUSH.

On first consideration of the report of the treasurer of the Rush Monument Fund the promoters of this fund might have cause to be discouraged. This is not the case however. They well know it has been the history of similar efforts in the past. Witness the Washington Monument, or, of more recent date, the Garfield and Grant memorials. The committee in charge, therefore, resolved to redouble their efforts and not to allow any act to be wanting, that may contribute to the success of the object of the American Medical Association, which at this late day desires to honor Benjamin Rush, the Sydenham of America.

In spite of a moderately thorough canvas, we learn that the contributions thus far, from the State of Pennsylvania, are comparatively insignificant. The medical profession of this State should gladly welcome a chance to honor Rush, the Physician.

The University of Pennsylvania and the alumni of that venerable institution should contribute handsomely for the honor of Rush, the Teacher and Scholar. The State of Pennsylvania, though most tardily, should recognize by a large donation the valuable services of Rush, the Statesman. And the city of Philadelphia should in this manner pay tribute to the man whom she should have

enrolled among the first of her many charitable citizens for his services in the yellow fever and other epidemics,—Rush, the Philanthropist.

We trust the medical profession will not turn a deaf ear to this appeal for a most worthy object.

A DOCTOR SHOT.

A sad story comes from New York of a physician of Williamsburgh, who was murdered in cold blood by the husband of one of his patients. The reason given for the shooting may be inferred from the relation of the doctor's patient to the murderer. The facts of the case will no doubt be made known in due time. But before they are known it may be worth while to consider the risks which a physician may run in the discharge of his duty. The first risk is to his own character. The relations of a physician to his women patients are often so intimate that one who has not firm principles to sustain him may give way, and shame, and disgrace, or even death may follow.

On the other hand, there can be no doubt that weak designing women may bring any or all of these catastrophes upon the head of an innocent man. As Potiphar's wife accused Joseph, so in modern times have men, who have resisted a thousand temptations, been accused. No virtue and no prudence can protect a man wholly against such accusation; nevertheless a medical man may lead such a life, and enjoy such a reputation for purity that a false accusation is in the highest degree unlikely to be made against him, and if made, it will be very unlikely to be believed.

To the credit of our profession it may be said that above all others it is distinguished for the faithfulness and integrity with which it performs the most difficult and most dangerous offices. It is a glory that in spite of occasional accusations and rare wrongs, it still retains the confidence of the community, which implicitly trusts to the physician that which it holds most sacred. This confidence rests upon the honor of every man in the profession, and let every man cherish it and make it stronger by his own integrity.

A HANGING EXPERIMENT.

In discussing the probable hanging of a young man convicted of murder, one Richard Allen, a citizen of Vincentown, N. J., recently expressed the belief that hanging was painless, and said any one could avoid being strangled by the rope,

by holding his chin in a certain position. As his hearers doubted the statement, Mr. Allen agreed to give a practical illustration of his statement, by allowing them to string him up for a minute or so, provided they would allow him to adjust the noose. This was done, and his friends pulled him up. But the rope fouled, and, before they could cut him down, he was unconscious. At first it was feared he was dead, but he finally recovered consciousness.

The rapidity with which this foolish man became unconscious furnishes some confirmation of an opinion recently expressed to the French Academy of Science, by Brown-Séquard, that congestion of the larynx produces an inhibitory action upon the medulla and respiratory centres, and may be the cause of that in hanging, when the neck is unbroken and when there is no complete obstruction to the entrance of air to the lungs.

BLISTERS FOR INFANTS.

The lamented Archambault, whose experience and clinical judgment no one will question, closed a lesson upon the employment of blisters in the treatment of infants with these words: "If I am still in doubt as to the good effects which I have thought I might attribute to blisters in some rare cases, I am absolutely convinced of their bad influence in a great number of cases; and, to speak more concisely, I am not sure that I have ever seen them do good, while I am very certain that they have often done much harm."

It will do no harm to recall from time to time some precept, which will put us on guard against ourselves. Let us reflect upon the wise words of Dr. Archambault which we have above quoted, and, when we apply a blister to a young child, let us not fear in following his counsels to err by excessive caution. "I was surprised," said Archambault, "to see one of my old preceptors prescribe blisters which seemed to me extremely small. 'In ordering a large blister,' said he to me, 'I am not very sure to do good, and I may do harm. With a very small one I do not fear this latter result.'"

IDEAS AND INDEXES.

Every literary production which contains many distinct subjects of thought should be accompanied by an index. Other things being equal, the size of the index indicates the number distinct concepts discussed in the body of the work.

The index which accompanied the last

number of the REPORTER occupied twenty pages of fine type, and gives a clue to the chief ideas presented in the journal during the past six months. Instead of allowing the index to crowd out the reading matter of that issue we adopted the rather unusual and expensive method of adding one form of sixteen pages to the thirty-two which every week constitute the regular body of the journal. This left us still four pages in debt to our subscribers, a debt which it gives us pleasure to expunge in the four extra pages of the present number.

NOTES AND COMMENTS.

Quinine in Infantile Colic.

There is a disease, known among old women as *three-months colic*, that torments infants, and not them alone, unfortunately, for they are none the worse for wear. Would that the same could be said of parents, nurses and neighbors. Such a disease really and truly does exist, but, in my reading, not in the text-books, or if so it appears under another name. The age at which it develops is generally about the second week after birth. During the day the infant sleeps sweetly and soundly, but as the shades of night deepen the little stranger begins to exercise his lungs, which practice he continues for from two to eight hours. Paregoric, Dewee's carminative, calomel, *et sui generis*, alleviate, palliate somewhat the suffering of the little screamer. The bowels are hard, the legs drawn up, rumblings are heard over the abdomen, and frequently an escape of gas is followed by complete relief of pain. From having made the night up to this time hideous, he relapses into angelic sweetness. We flatter ourselves that the key to the disease has been found, and address ourselves with renewed energy to the digestion, using largely the carminatives, purgatives, etc. Thus we continue day after day, and the child serenely, night after night, continues his serenade. As said before, he is none the worse for wear; he thrives on adversity. No babies are healthier-looking, fatter or so plump. I have had two such children in my own family, or rather one went the full three months despite all and every remedy he took, and five doctors and all the old women tried their hands on him without relief. He could take a drachm of paregoric at a dose when two months old and other narcotics in proportion. He finally wore it out, I reckon; I am sure he did every one else. The other boy started

off in the same way and so continued for two weeks, when I concluded, what I ought to have seen before, that the disease being periodical in character, and not attended with fever, was neuralgic, and that I would give him the benefit of the great antiperiodic, quinine. After the first night the neuralgia of the bowels was *cured*, and did not return for fourteen days, when, as by magic, it again vanished under the potent drug. I have used it in every case of this kind since, and with the same unvarying and gratifying success. It might be urged that the disease was malarial, but the absence of fever and the sweating stage, and the continual growth of the child, I think negative this view. My friend and colleague, Dr. Taliaferro, tells me that three of his children afflicted him with the affection in question, and resisted all curative agents. I have had in my practice the pleasure of curing about eight cases, all that I have seen, since this mode of procedure was first adopted by me, and so far as I know it is original with me. Dr. James A. Gray has tried this treatment and informs me, with success in every case. I submit these notes for the benefit of both parents and the child. I used the following formula:

R. Quin. sulph. gr. ix.
Hydg. chlo. nit. gr. iii.
M. ft. chart. ix.

Sig.—One at 9, 12 and 3 each day.

Prof. J. S. Todd, M. D., in *Atlanta Medical and Surgical Journal* for June, 1887.

Anæsthesia by Vibration.

In the June number of the *Independent Practitioner*, Dr. F. H. Brimmer, of Minneapolis, gives an interesting account of a dental operation in which he practically anæsthetized the pulp of a sound tooth by holding a rapidly revolving spear-shaped drill in contact with it for fifteen or twenty seconds, so lightly as only to transmit the vibrations. The drill was then pressed against the tooth with a little more force, and, the sensibility being found diminished, was allowed to penetrate perhaps a third of the distance to the pulp, when it was used again as at first. At the third trial the drill entered the pulp. Crystals of carbolic acid were then forced to the end of the root with a probe, and in twenty-three minutes the tooth was cut off and properly shaped for a crown, which was set on the following day. Dr. Brimmer remarks that the mitigation of sensibility by means of the dental engine is not a new idea. He thinks that the reason that its employment is not more commonly successful is that the operator allows the in-

strument to make progress at the same time. The theory is that there is a limit to nervous conductivity, and that the conduction of the vibrations exhausts it for the time being.

MODERN TREATMENT OF COMMON DISEASES.

Diarrhea of Children.

Sensemann recommends the subnitrate of bismuth, gr. iij-vj hourly, as almost a specific. Rossbach praises naphthalin, though not wholly free from irritating effects upon the kidneys and bladder. It is best given in doses of gr. $\frac{1}{3}$ -ij-xv several times daily, in keratin or gelatin coated pills. Sansom gives calcium sulphocarbonate for infantile diarrhea. On account of its ready solubility it is the best of chalk preparations. Ten parts contain 1.8 parts of calcium. Stephenson recommends phosphate of sodium in small doses for diarrhea infantum, and in chronic catarrh of the small intestines and dyspepsia of children, Mayr uses pasta guarana (guarana uva) as an astringent, in doses of gr. v-xx with sugar, three times daily. A widely used remedy in diarrhea infantum is cornu cervi raspatum as a decoction.

- R Cornu cervi rasp. 3 xiiij
Ext. glycyrrhizæ. 3 ijss
Cort. cinnam. cass. 3 ss
M.—Make into a tea.

Another remedy well recommended is cascarilla bark; take ℥iv; macerate for half an hour in ℥xx hot water, filter and add cinnamon syrup ℥v. Sig.—A teaspoonful every hour.

Wendt gives the following for chronic diarrhea infantum:

- Extr. calumbæ. 3 j
Decoct. salep. 3 ijss
Elæo sacch.* fœniculi 3 iv
M. Sig.—One teaspoonful hourly (*to be shaken.*)

For gastric and intestinal catarrh of children a safe prescription is:

- R Hydrarg. chlor. mite. gr. $\frac{1}{2}$
Pulv. gummos. gr. vijss
M.—Make into 10 powers. Sig.—One every three hours.

For the same with green-colored stools:

- R Hydrarg. chlor. mite. gr. $\frac{1}{4}$
Pulv. rad. rhei. gr. $\frac{3}{4}$
Conch. præp. gr. ivss
M.—Make into 8 powders. Sig.—One powder three or four times daily.

* [An intimate combination of ethereal oil and sugar, gtt j to 3ss. Used when the oil is to be added to a liquid; to disguise an unpleasant taste; adjuvant to powders; and lastly as a vehicle of the ethereal oil itself. Frequently used by the Germans.]

Lebert advises logwood, ℥i boiled in water ℥iv and strained. To this add ℥viijss of simple syrup. Sig.—A teaspoonful hourly.

For diarrhea of children with acid stomach is recommended:

- R Sodii bicarb. gr. xv
Mucilag. gummi arab. ℥ iv
Tinct. rhei. aquos. 3 ss
Syr. aurant. cort. 3 vijss
M. Sig.—A teaspoonful every one or two hours.

For weakness of digestion and asthenic diarrhea Wendt gives:

- R Rhizom. calami. 3 ss
In aqua ferv. q.s. and filter; add;
Gummi arab. 3 j
Sacchari. 3 ij
M. Sig.—A teaspoonful every two hours.

Ipecacuanha root is recommended by Guéneau de Mussy in diarrhea infantum.

The following formulæ are largely used in the early stages of the summer diarrhea of children:

- R Tinct. opii deodorat. ℥ xvi
Bismuth. subnitrat. 3 ij
Syrupi. 3 ij
Misturæ cretæ. 3 xiv
M. Sig.—Shake: One teaspoonful every two to four hours.

- Bismuth subnitrat. 3 ij
Pulv. ipecac. comp. gr. ix
M.—Make it into twelve powders. Sig.—One powder every three hours.

For cholera infantum the following is serviceable:

- R Tinct. opii deodorat. ℥ xvi
Spts. ammon. aromat. 3 j
Bismuth. subnitrat. 3 ij
Syrupi. 3 ss
Misturæ cretæ. 3 iss
M. Sig.—One teaspoonful every two or three hours.*

For the more chronic cases of these complaints muriatic acid and pepsin saccharat. may with advantage be substituted for the chalk.

Money advises the following:

- R Bismuth. subnitr. gr. iv
Sodæ bicarb. gr. iv
Pulv. tragac. co. gr. iij
Spt. chlorof. ℥ ij
Aq. carui. 3 ij t.d.s.

When improvement has set in, and to succeed the other agents, Goodhart recommends:

- R Liquor ferri. nitratis.
Acidi nitrici dil. āā. 3 ss
Syrupi zingiberis. 3 j
Aque. q.s. ad 3 ij M.
Sig.—One teaspoonful three times daily, for a child of two years.

* An infant of six months can take one-half the dose of the last three formulæ above given, and one of three months, one-third the dose.

Conby, of Paris, describes the symptomatology and etiology of this affection, stating that, in Paris, the mortality from this disease during the summer is 600 per month. He advises the use of dietetic measures, the subnitrate of bismuth and laudanum. In the severer cases the writer recommends the following prescriptions which we quote from the *Medical News*, June 25th, 1887:

Aque destillat.,.....3 12½
Syrup lydon.....3 5
Acid hydrochloric. dil.,.....℥ 8—M.

Sig. Teaspoonful every two hours.

Sacch. pulver.,.....3 2½
Naphthalin,.....gr. 15
Iodoform,.....gr. 3
Ol. bergamot,.....gtt. 2—M.

Ft. in chart. 20 in num.

Sig. One powder every hour, in milk.

Naphthalin,.....gr. 8
Spirit. vini gallici,.....3 2½
Syrup. altheæ,.....3 12½ M.

Sig. To be taken during twenty-four hours, in teaspoonful or coffee spoonful doses.

Wm. & L. J. Ripley
CORRESPONDENCE.

Quinine in Pneumonia.

EDS. MED. AND SURG. REPORTER:

Your invitation to contribute further to the value of quinine in pneumonia, was perhaps made without knowing that the paper briefly reported in the discussion of Dr. Ripley's paper, has since been published *in extenso* in the *New York Medical Journal*, (May 28, and June 4th.) To this paper I would now beg leave to refer. In addition I would observe: That it seems to me that Dr. Ripley's data were too few for the conclusions based on them, and the investigation started from a conception of quinine altogether too narrow. That the temperature of the patient should not be reduced within twelve hours after taking the drug, would show indeed that as a symptomatic antipyretic quinine was inferior to many others. It does not, however, by any means follow that quinine is valueless in pneumonia; for it is far from true that the principal indication in pneumonia is the reduction of temperature.

It is indeed difficult to explain why the views on the dangers of high temperatures which have grown up from the study of continued fevers, should have become applied to fever of brief duration like pneumonia. Whether the rise of temperature in this disease be simply symptomatic of the pulmonary inflammation, or whether that and the fever be coincident symptoms of an un-

derlying morbid agency, the importance of a fall of temperature lies in the proof thus (generally) afforded, of an arrest of the morbid process. The fever rarely lasts long enough in pneumonia to cause organic degenerations, when it becomes symptomatically dangerous by causing convulsions, or even by threatening functional paralysis of the heart, it cannot to-day be denied that we possess more prompt and potent agencies to combat it than quinine. The real value of quinine remains unchanged; to lessen pulmonary congestion, to increase the force of the heart by increasing both its diastolic and (indirectly) its systolic movement; to (probably) directly influence the nervous force both of the cardiac ganglia and the central nervous system.

In the paper referred to, I have tried to show where, for these purposes, moderate doses of quinine were preferable to large doses, and why we might anticipate danger from the latter. But I do not understand Dr. Corson's general denunciation of quinine as a dangerous agent.

It is very certain that in malarial districts, as Dr. Maxwell remarks, many cases of extensive pulmonary congestion are simply an expression of malarial poisoning, of the same nature as other visceral congestions, of the spleen, or liver, or stomach. I remember seeing a case in the wards of M. Michael Peter, in Paris, where an overwhelming pulmonary congestion was apparently dissipated by venesection, and the Professor utilized the case in a brilliant clinical lecture upon the occasional timeliness of this now almost obsolete method. But on the third day from the bleeding, all the symptoms and all the physical signs returned. The patient was then treated by quinine, as if for a tertian ague, and was rapidly cured.

The greatest difficulty in the administration of quinine to children, is certainly its tendency to produce vomiting, and this may not unfrequently necessitate its cessation. Still, the method of divided doses, (2½ grains at 6 p. m., the same at 7 p. m., again at 7 and 8 a. m.,) succeeds in large numbers of cases, every one knows that the administration of quinine in intermittent fever was for a long time opposed on the ground that it would increase the gastric irritation which usually existed then; that the rule was laid down to make every effort to allay this irritation in order to "prepare the system" for the quinine, only the frequent failure of such preparation, and consequent necessity of administering quinine while all the symptoms of gastric irritation persisted, finally

showed that these were not necessarily, nor even usually, aggravated by the drug.

The utility of quinine in chronic pneumonia, where consolidation (non tuberculous,) persists after defervescence, is a most interesting fact, and not apparently the best known. It seems to me to strangely confirm the view that quinine is useful, not for the fever of pneumonia, but to antagonize the congestion of tissue surrounding the hepatized portions of the lung.

110 W. 34th St., New York City.

The Proper Mode of Preparing Ferric Salicylate, or Mistaro Ferro-Salicylata.

EDS. MED. AND SURG. REPORTER.

In the endeavor to mix the following formula: Sodii salicylatis, $\mathfrak{z}$ iv; glycerini, $\mathfrak{f}\mathfrak{z}$ ij; ol. gaultheriæ, $\mathfrak{m}$ xx, tr. ferri chloridi, $\mathfrak{f}\mathfrak{z}$ lv; acidi citrici, gr. x; liq. ammonii citrat., (B. P.) q.s., $\mathfrak{f}\mathfrak{z}$ iv; for the production of ferric salicylate, I found that not only was active effervescence produced, but an inky mixture resulted attended with a dark precipitate as soon as the tr. ferri chloridi was added; but after much rubbing together with the addition of the liq. ammonii citrat., the inky appearance of the solution disappeared, and it assumed a reddish-brown color. In order to avoid the inky appearance of the mixture, and the effervescence during the preparation of the formula, I devised the following, which obviated these objections:

R	Liq. ammonii citrat., (B. P.)	 $\mathfrak{f}\mathfrak{z}$ jss
	Acidi citrici, ...	gr. x
	Tr. ferri chloridi, ...	$\mathfrak{f}\mathfrak{z}$ iv
	Glycerin, ...	$\mathfrak{f}\mathfrak{z}$ ij
	Ol. gaultheriæ, ...	$\mathfrak{m}$ xx
	Sodii salicylatis, ...	$\mathfrak{z}$ iv

M.

The mixture should be made in a graduated glass measure of eight ounce capacity. Into it should be first put the ounce and a-half of liq. ammonii citrat., then add the ten grains of citric acid; and after the slight effervescence ceases, pour in the tr. ferri chloridi, and stir well with a spatula until all effervescence ceases; then put the two ounces of glycerine, by measure, in another glass, and add to it the twenty drops of ol. gaultheria, and mix intimately with a spatula; and when well mixed pour it into the first part of the mixture, and stir well together with the spatula; then finally add the $\mathfrak{z}$ iv of sodii salicylatis, and stir well until all the salicylate of soda is dissolved, and a beautiful wine-red solution will be the result, ready for use; measuring four fluid ounces.

Each fluid drachm contains seven and a-half grs. of sodii salicylatis, and seven and a-half drops of tr. ferri chloride. I have found it better to begin with a teaspoonful dose in a half wine-glass of water, three or four times a day, and gradually increase the dose to two teaspoonfuls four times a day. In the treatment of rheumatic affections of either an acute or chronic character, I usually add twenty drops of the tincture of colchicum seed to each drachm of the solution, and if the heart's action is weak and palpitating, I also add to each drachm, ten drops of tincture of digitalis. Persons suffering with anæmia always complain of palpitation of the heart, and the addition of the tincture of digitalis to the ferric salicylate mixture always increases its beneficial effects.

J. B. JOHNSON, M. D.

Washington City, D. C., June 20, 1887.

Treatment of Goitre.

EDITORS MED. AND SUR. REPORTER:

Sirs:—Please give your experience in the treatment of Goitre by the Hypodermic method, giving injection used, if any, and strength.

O. C. STRICKLER.

New Ulm, Minn., May 5, 1887.

[The treatment of goitre by injection into the tumor has many warm advocates, is practiced with safety in the great run of cases, but is always attended with risk. Cohen * says: "I have heard of fatal results following these injections, so shortly as to be attributable to the operation. In one instance the tumor had been injected several times with impunity, but the patient died in the carriage in which she was being transported as usual to her residence." For our own part, in view of the possibility of fatal accident in a disease not of itself fatal, we have not felt justified in resorting to the method.

Mere hypodermic injections—over the tumor—are usually of ergotine, and in most cases fruitless. Injections *into the substance* of the gland are chosen with reference to the nature of the goitre and the effect desired. Cystic goitres are usually evacuated by puncture with a trocar, and the cavity injected with alcohol, carbolic acid, tincture of iodine, or tincture of chloride of iron. The injection is retained in position for minutes, or even hours, by plugging the cannula, the idea being to excite adhesive inflammation. Carbolic acid may be injected without evacuation of the cyst—one to two or three drops of the undiluted acid. Fibrous goitres

* Diseases of Throat, etc., 2d Edition, N. Y., 1879, p. 711.

may be injected with the hope of exciting suppurative inflammation, with disappearance of the tumor by absorption, or by spontaneous or artificial discharge. In this case irritating substances are used, such as tincture of chloride of iron, five drops and upwards, or Fowler's solution up to ten drops, etc.

If the idea be to promote absorption, preparations of iodine are employed, such as tincture of iodine, five to thirty drops. Other solutions sometimes used with good effect are: Carbolic acid, 1-5 drops; saturated solution of ergotine, 5-30 drops; osmic acid, 1-10 drops of a one per-cent. solution, etc.

We should advise our correspondent to try inunctions, such, for example, as iodine in lanolin, 20-30 grs. to the ounce, before resorting to injections.—EDITORS OF THE REPORTER.]

Bichloride of Methylene.

EDS. MED. AND SURG. REPORTER :

Will you kindly inform me through the REPORTER if the Bichloride of Methylene has come into very extended or general use as an anesthetic, and what is its relative value compared with chloroform or ether? Does Spencer Wells still use it in preference to other anesthetics in Ovariectomy? Who makes a pure article? What is its cost? By answering the above you will greatly oblige a constant reader. W. N. SHERMAN.

Winslow, Arizona, May 5, '87.

[We have referred this letter to Dr. Lawrence Turnbull, who has kindly sent the reply that appears on another page. If Dr. Sherman will write to any of the manufacturing chemists who advertise in the "REPORTER," he will receive reliable information as to cost, etc. We have made it a rule to exclude all commercial matters from the reading-matter pages of the REPORTER, and although, as now, adherence to this principle makes us sometimes appear disobliging, we are sure the principle is right. Our subscribers pay for thirty-two pages of new ideas every week; to insinuate into those pages any masked advertisement, or so-called "reading-notice," or anything which could be construed as such is to defraud the subscriber and lower the dignity of the Journal.

—EDITORS OF THE REPORTER.]

—Two plugs of tobacco placed in a jug of whisky by a small boy caused fifteen cases of tyrotoxicon ice cream poisoning at a recent festival.—*Western Druggist*.

Homœopathy.

EDS. MED. AND SURG. REPORTER :

The question has been asked whether homœopathy is on the increase, and, if so, the cause. I can answer emphatically *yes*. Many are having a very lucrative practice, from the fact that they make a visit and furnish the medicine for one dollar, while the regulars charge for visit and prescription two dollars, and in addition the druggist will charge from 75 cents to \$1.50 very often, which makes it very expensive, besides the trouble of going after it; and, at night time, matters are delayed in rousing up the druggist, etc. Then, too, many are fearing mistakes. Then, again, many look back to former days, when doctors furnished their medicines; and they were excellent doctors. I know from personal observation that those who furnish their medicine are getting very fine practice, and I verily believe the time is not far distant when the regulars will be compelled to furnish their remedies, which could be done with much less labor than forty-five years ago, when I commenced the practice of medicine. I observe another fact, that many druggists are becoming wealthy in a few years. Many patients go to them for advice and medicine to avoid the doctor's fee, and they have the very best formulas on hand to resort to. I remember, five years ago, I gave Maj. King a prescription for cough mixture, at a time of general colds. It had the desired effect, and, becoming known in that locality, the druggist put up in one week over twenty bottles of "Maj. King's cough syrup." Now, if I had furnished the medicine, I should have had the benefit.

DR. P. P. WERNER.

Washington, D. C., June 18th, 1887.

Pleasant to Take.

EDS. MED. AND SUR. REPORTER :

I am very glad to observe that you "know a good thing when you see it," and that you are very honorable in giving credit for your *Excerpta*. The paragraph on a Method of Inducing Respiration in Newly-born Infants, was published originally as a *letter* in the REPORTER, vol. lvi., p. 527, and in the same journal amplified to the proportions of a *communication*, vol. lvi., p. 230. Of course, this coming home of the chickens to roost, is very pleasant to the writer, who likes to see his "bairns respected like the lave."

I am glad to observe that the REPORTER loses nothing of its vigor by the change of editors, notwithstanding the transposition was extremely sudden.

I shall watch the gladiatorship of Messrs. Corson and Maxwell with considerable interest, as my connection with cases of pneumonia as well as my use of quinia has been somewhat unique and suggestive—to myself, at least. I wish you great success in your journalistic career, and the principles upon which you make your foundation are such as I believe are sure to bring about this desirable result.

I am very truly and sincerely yours,
E. T. BLACKWELL.

Cedarville, N. J., June 14, 1887.

EDS. MED. AND SURG. REPORTER:

As the books of the REPORTER will show, I have been a subscriber for quite a number of years, and I do not now intend to deprive my *patients* of its benefit to myself, and through me to themselves. * * *

C. A. CHATHAM, M. D.

Dawson, Ga., June 23d, 1887.

EDS. MED. & SURG. REPORTER:

I think you are improving the REPORTER. Being an old friend of the journal, I am glad to see it.

Respectfully yours, R. G. ALLEN, M.D.
Washington, Ill., June 22, 1887.

NEWS AND MISCELLANY.

The Care of Milk.

The subject of tyrotoxon, the peculiar poisonous ptomaine developed in the incipient decomposition of milk and cheese, has become identified with the name of Prof. Vaughan, of Ann Arbor, Mich. The very suggestive and instructive studies of this observer lead us to believe that in many cases of summer diarrhoea in infants, the symptoms of irritation are caused by the development of the ptomaine in question. In the *Medical News* of June 18, 1887, Prof. Vaughan presents the following practical points in regard to the relation of milk deterioration to cholera infantum:

Preventive measures will consist for the most part in attention to diet, and especially to milk. I have drawn up the following rules concerning the care of milk:

1. The cow should be healthy, and the milk of any animal which seems indisposed should not be mixed with that from the perfectly healthy animals.

2. Cows must not be fed upon swill, or the refuse of breweries, or glucose factories, or any other fermented food.

3. Cows must not be allowed to drink stagnant water; but must have free access to pure, fresh water.

4. Cows must not be heated or worried before being milked.

5. The pasture must be free from noxious weeds, and the barn and yard must be kept clean.

6. The udders should be washed, if at all dirty, before the milking.

7. The milk must be at once thoroughly cooled. This is best done by placing the milk can in a tank of cold spring water or ice water, the water being of the same depth as the milk in the can. It would be well if the water in the tank could be kept flowing; indeed, this will be necessary, unless ice water is used. The tank should be thoroughly cleaned every day, to prevent bad odors. The can should remain uncovered during the cooling, and the milk should be gently stirred. The temperature should be reduced to 60° F. within an hour. The can should remain in the cold water until ready for delivery.

8. In the summer, when ready for delivery, the top should be placed on the can and a cloth wet in cold water should be spread over the can, or refrigerator cans may be used. At no season should the milk be frozen; but no buyer should receive milk which has a temperature higher than 65° F.

9. After the milk has been received by the consumer, it should be kept in a perfectly clean place free from dust, at a temperature not exceeding 60° F. Milk should not be allowed to stand uncovered, even for a short time, in sleeping or living rooms. In many of the better houses in the country and villages, and occasionally in the cities, the drain from the refrigerator leads into a cesspool or kitchen-drain; this is highly dangerous; there should be no connection between the refrigerator and any receptacle of filth.

10. The only vessels in which milk should be kept are tin, glass, or porcelain. After using the vessel it should be scalded, and then, if possible, exposed to the air.

—A committee of the Association of German physicians has sent a circular to the directors of all the gymnasia of Germany, asking them to dissuade students from adopting the medical profession. Accompanying the circular are statistics which show the proportion between the number of physicians licensed each year and the number who die or retire from the profession.

Hepatic Erysipelas.

The Paris correspondent of the "British Medical Journal" says: "In the 'France Médicale,' Dr. Louis Boucher recently described a case of hepatic erysipelas in a woman aged sixty-three. Eighteen years previously she had received a blow on the right side of the abdomen. Bilious fever, with severe jaundice, gastric disturbance, and obstinate constipation ensued. The menopause occurred without any complications. In 1879 the patient was attacked with erysipelas, after violent hepatic pains, which lasted two days. On January 3, 1887, she was suddenly seized with fever and tremors and a recurrence of the hepatic pain. The temperature was 39.2° C. (102.4° F.), the pulse 120. The urine was deep red; the tongue white. She complained of intense pain in the region of the liver, which was hot, as if it were the seat of inflammation. No alteration of shape could be detected. An opium-poultice was applied, and a sedative given at night. The following day the patient was very restless; her sleep had been interrupted by nightmare and starts; the fever was worse. Ten centigrammes of extract of digitaline were ordered every hour. Toward night the pains in the liver disappeared, but the throat was dry, there were pains in the ear, and the face became swollen. On January 6th, well-marked erysipelas showed itself, and spread from the lobe of the ear over the right side of the face; the temperature fell to 38° C. (100.4° F.). Recovery took place in a few days. . . ."

Distilled Water in Eye Lotions.

Physicians and pharmacists generally assume that distilled water is the best means of dissolving drugs, and in the great majority of instances this is undoubtedly the case. As a rule, the solvent should be absolutely pure and neutral in itself; but in some instances this very neutrality of the solvent may interfere with the intended action of the substance dissolved. A curious illustration of this exception to the rule was given some time ago by an eminent English oculist in a communication to a London journal. Our readers know that an aqueous solution of boracic acid is one of the most useful of eye lotions; but we remember that, as prescribed for the writer several years ago by one of the best oculists in this city, the order was for "ten grains in *distilled water*." Our English expert, however, says he has found that when the lotion is made of distilled water, its use is attended with some discomfort and smarting; and,

what is more singular, the irritation is even greater when there is no boracic acid in solution. "Anybody," he says "can verify for himself that a drop of distilled water in the eye seems to be a most unpleasant and foreign element."

The simple explanation of this is, that well or spring water contains salts in solution which make it slightly alkaline, thus rendering it somewhat more neutral to the conjunctiva, a tissue ordinarily bathed in the lachrymal secretion, which contains about one per cent. of solids, chiefly chloride of sodium, or common salt. The addition of two grains and a half of this salt to the ounce of distilled water renders any lotion for the eye more soothing and more beneficial. This, our friend says, he has verified by experience; and we commend the fact to the attention of oculists and others interested.—*Popular Science News*.

Illegitimacy in Europe.

An editorial in the *Medical Record*, June 18, 1887, states that Dr. H. Holland, of Westfield, Mass., has collected some statistics which show a most striking increase in the number of illegitimate births in Europe. In Austria over one-half the births are illegitimate. In Vienna, among 1000 births 509 are illegitimates; at Prague, 505. In Styria, Carinthia and Olmutz, the ratio is from 646 to 702 illegitimates out of 1000 births! A high rate of illegitimacy seems to prevail throughout Germany.

The proportion of illegitimates in Paris is 1 to 3, in all France 1 to 12, in Great Britain 1 to 15, in Spain 1 to 18.4, in the Netherlands 1 to 23, in Italy 1 to 27.8, and in Greece 1 to 78.6. The low rates are due to the population being more largely rural. During ten years Austria had nearly a million of illegitimate births.

A point of great medical interest is the fact that illegitimates are apt to be victims of disease. In many respects they are inferior to legitimates. They are often conceived during a debauch, or in moments of intoxication, and are likely to be brought up in neglect, poverty, and misery. According to Bouchut, the mortality among foundlings in Paris is fifty-five per cent. in the first year of life, and sixty-three per cent. in the second year of life. Such a rate is far greater than exists in many other cities; but it indicates the excessive amount of disease among this unfortunate class.

Dr. Holland quotes Legoyt as stating that the number of illegitimate births is increasing in Europe.

Scintillations by the Late Dr. Moxon.

A posthumous volume of Dr. Moxon's aphorisms has just been issued, from which we extract a few isolated gems:

"Knowledge is fuel, not fire."

"He [the physician] cannot classify diseases, because what he knows of them is not comparable knowledge. For while one disease is a pain in the leg, and another a growth in the stomach, and another a spider in the skin, the classification of them is worse than mixing incompatibles—it is mixing things indifferent. It is like trying to mix the solar spectrum and the key of C major with essence of peppermint."

"I pity the lecturer on medicine: he is under the greatest of all burdens—the burden of the uncommunicable; and you are happy when he is one of those great men who can nearly say what cannot be said."

"Without the doses three times a day, the service would not go on; they unite the attention of doctor, patient, nurse, and friend in a periodic series of efforts, something not unlike those little yells a group of sailors make in turn when they are hauling hard on a cable, without which it appears the cable would never come along, although there is no apparent force in the noises they make. A doctor without physic is like a priest without a creed, or a poet without a rhyme."

"Knowledge is not power. Power arises by training in the use of knowledge. Consider the difference between training and teaching. The teacher carries over the things he knows, and fixes them in the learner's memory; the trainer takes what is in the memory, and converts it into an organ for the pupil's own use."

Colonial and International Congress on Inebriety.

This Congress will be held in London, Eng., on Wednesday, July 6th, 1887. The following papers are announced:

Norman Kerr, M. D., F. L. S., President, Opening Address—"Inebriety, a Disease requiring medical, moral, and legislative treatment." Mons. le Chevalier Max Proskowetz de Proskow Marstorff, President of the Austran Inebriety Society, "Inebriety in Austria." N. S. Davis, M. D., President International Medical Congress, "Inebriety, a Disease." Professor Binz, Bonn, "The German Law on Inebriety." Dr. Moeller, Brussels, "Inebriety in Belgium, from a Medical and Legal point of view." Clark Bell, Esq., Ex-president Medico-Legal So-

cietiy of New York, "Jurisprudence of Inebriety." Joseph Parrish, M. D., President American Inebriety Society, "American Inebriety." T. D. Crothers, M. D., Editor *Quarterly Journal of Inebriety* "Rise and Progress of Remedial Treatment of Inebriety." E. C. Mann, M. D., Brooklyn, U. S. A., "Pathology of Inebriety." L. D. Mason, M. D., Consulting Physician, Fort Hamilton Home for Inebriates, "The Relation of Disease to Inebriety." Rev. Dr. De Colleville, Brighton, "Continental Legislation for Inebriates." Rev. J. W. Horsley, M. A., "A Prison Chaplain's Observations on Inebriety." Alfred Carpenter, M. D., J. P., "The Meeting-place of Vice and Disease." Surgeon Major Pringle, M. D., "Homicidal and Suicidal Inebriety." President, "Colonial Legislation for Inebriates."

All the Visitors to the Congress and others interested in the inebriate are invited to a Reception to Dr. T. D. Crothers, Hon. Sec. of the American Association for the Cure of Inebriates and Editor of the *Quarterly Journal of Inebriety*, by the President and Council of the Society for the Study of Inebriety, in the Rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, London, W., on Tuesday Afternoon, 5th July, 1887, at four o'clock p.m. Tea and Coffee.

Homœopathy as it is.

The *Medical Times*, a homœopathic journal of New York, says: "We do not believe there is a single member of the faculties of the so-called homœopathic college, in New York and Philadelphia who does not almost daily administer remedies which in no sense can be called homœopathic. In name they are sectarian, fighting with all their force for a name which binds them to exclusive practice, and yet in the sick-room unsectarian, broad and liberal, bringing to their aid facts and suggestions culled from a large reading of the literature and experience of all schools. Dr. T. F. Allen, at one time one of the most enthusiastic apostles of so-called high-dilution homœopathy, now admits that it is unreliable and delusive, and says that homœopathy should be taught in all medical schools, but it should constitute only a part of the course of study. We do not hold that homœopathy is the exclusive and only law of healing."

—At Valparaiso, Chili, up to May 21st, there had been 899 cases of cholera and 628 deaths. In Quillota there had been 1959 cases and 1002 deaths.

Food Adulterations.

Much attention has been attracted of late to the presence of dangerous ingredients in certain articles used by confectioners and bakers, and especially to lead chromate, which is used as a coloring agent for cakes. Cream-puffs have been found to contain appreciable quantities of the salt and now it has been detected also in cinnamon cake.

Dr. Henry Leffman has recently analyzed a piece of a cinnamon cake which had been furnished him by Medical Inspector Taylor, of the Philadelphia Board of Health, and reported that an examination of the sample showed very decided indications of lead.

Dr. Leffman added that there appeared to be a sufficient amount of lead in the sample inspected to constitute a case of chronic poisoning if similar cake was constantly eaten.

A Vindication.

Among the proceedings of the Kentucky State Medical Society, at its recent meeting, at Paducah, we note that the following resolutions were unanimously adopted:

Resolved. That the recent published attack upon the personal and professional reputation of Dr. Dudley S. Reynolds is unfounded and unjust.

Resolved. That the Kentucky State Medical Society in regular session assembled, bear testimony to the high professional and social standing of Dr. Reynolds, and repel the aspersions against a physician who for fifteen years has ranked among its foremost members.

We congratulate our colleague upon this action of his State Society and upon the good will and appreciation of which it is an evidence.

Picture of Charcot's Clinic.

In the *Scientific American* supplement, No. 598, June 18, 1887, there is a very interesting copy of a painting by M. André Brouillet, which was exhibited in the season of 1887, and which represents a clinic of Prof. Charcot, in the Hospital Salpêtrière. The professor is represented as lecturing upon a subject affected with hysteria. In his presence there is a large number of eminent men whose names are familiar ones in medical science, and whose faces it is interesting to see. The picture is one which attracted much attention in Paris, and will prove interesting everywhere.

Coriaria Thymifolia.

According to *Der Pharmaceut*, *Coriaria thymifolia*, growing in New Grenada, can appropriately be called "Ink Plant." The juice, at first red, turns beautifully black in contact with the air. This juice, called *chami* by the natives, can be used for writing just as it comes from the plant. It does not corrode steel pens.

Prize.

The Alumni Association of the College of Physicians and Surgeons of New York offer a prize of five hundred dollars, open for competition to the Alumni of the school, for the best essay upon any medical subject which may be submitted to the committee.

Reception to Dr. R. J. Levis.

The medical profession of Philadelphia gave a reception at the Hotel Bellevue on Tuesday evening, June 21st, to Dr. R. J. Levis, on the occasion of his retirement from active professional work.

Items.

—Diogenes would find it much easier to-day to find an honest doctor than to find one who has never given gaseous enemata.

—Dr. Schüller, a physiologist, intends to establish soon in Munich an "academy for the art of hygienic cooking."

—Dr. L. Turnbull will leave in July for Jamestown, R. I., and will remain until October 1st.

—Artificial pepper is prepared and sold in Hungary. It consists of wheat flour impregnated with an alcoholic tincture of pepper, and dried.

—A young lady giving her experience in a dentist's chair, said it was hardly as agreeable as a box at the opera, but better than being run over by the cars.

—Dr. C. B. Nancrede, has accepted an invitation to deliver the Course of Lectures on Surgery at Dartmouth College, New Hampshire, in the absence of Dr. P. S. Connor, in Europe. The course begins July 13th.

—"And what would you prescribe for the baby?" asked an anxious father of an absent-minded physician. "Oh! the usual thing," returned he. "Perfect quiet; no worry, exercise, amusement; no coffee; no spirits, and smoking only in moderation." }
—Exchange.

—Dr. Emery, of Brooklyn, reports the poisoning of thirty-two boys at an orphan asylum, from chewing the inner bark of the locust tree, which had been stripped from fence posts. This, we believe, is the first instance on record of poisoning from this cause. Locust bark should be investigated chemically.

OBITUARY.

DR. EDGAR FENN PECK.

Dr. Edgar Fenn Peck, who died June 21st, in Brooklyn, in his eighty-first year, was half a century ago one of the most active and useful citizens of New York. Dr. Peck was born in Dutchess county, N. Y., September 20th, 1806. He was a lineal descendant of Joseph Peck, who came over with Davenport's colony to New Haven in 1638. Dr. Peck removed to New York in 1831.

DR. WOOLSEY JOHNSON.

Dr. Woolsey Johnson, Health Commissioner of New York, died June 21st of Bright's disease, at the New York Hospital, where he had been for several weeks. Dr. Johnson was about fifty years old. In 1881 Mayor Cooper appointed him Health Commissioner for a term of six years, which ended May, 1887. He was a member of the New York County Medical Society and of the Academy of Medicine. He was attending physician at the New York Hospital, and surgeon for the Eye and Ear Infirmary.

DR. EZRA MICHENER.

Dr. Michener, a prominent physician of Chester Co., Pa., died at his home in Toughkenamon, June 24th, in his ninety-third year. He was a noted scientific writer and student of natural history.

DR. R. FOWLER.

At Eudora, Miss., on June 18th, 1887, Dr. R. Fowler, aged fifty years. His death occurred as a result of paralysis.

Official List of Changes of Stations and Duties of Officers.

Medical Corps of the Navy, for the week ending June 25, 1887:

Inspector, C. J. Cleborne, ordered for examination preliminary to promotion as Medical Director.

P. Asst. Surgeon, G. P. Lumsden, ordered to receiving-ship Franklin, Norfolk, Va.

Medical Director, P. J. Horwitz, permission to leave the United States for six months.

Asst. Surgeon, H. N. Harris, commissioned Asst. Surgeon in the Navy, June 13, 1887.

Medical Inspector, J. C. Spear, detached from Naval Laboratory and granted three months' leave.

Medical Director, Delevan Bloodgood, detached from Naval Hospital, Norfolk, Va., and ordered to the Naval Laboratory.

Medical Inspector, Michael Bradley, ordered to Naval Hospital, Norfolk, Va.

P. A. Surgeon, H. G. Beyer, remain on present duty until September 1, 1887.

P. A. Surgeon, C. G. Herndon, remain on present duty until June 17, 1888.

Stations and Duties of Officers serving in the Medical Department, U. S. Army, from June 19, 1887, to June 25, 1887:

Col. Chas. Sutherland, Surgeon, granted one month's leave of absence, with permission to apply for an extension of one month. S. O. 126, Div. of the Atlantic, June 23, 1887.

Lt. Col. A. K. Smith, Surgeon, will be relieved from duty at West Point, N. Y., on September 30, 1887, instead of August, 1887. S. O. 144, A. G. O., June 23, 1887.

Major C. H. Alden, Surgeon, leave of absence extended to include September 29, 1887. S. O. 144, A. G. O., June 23, 1887.

Major J. H. Bartholf, Surgeon, granted leave of absence for two months, to take effect about July 5, 1887. S. O. 141, A. G. O., June 20, 1887.

Capt. Charles Richard, Asst. Surgeon, sick leave extended two months on surgeon's certificate of disability. S. O. 139, A. G. O., June 17, 1887.

Capt. Jno. J. Cochran, Asst. Surgeon, granted leave of absence for one month. S. O. 143, A. G. O., June 22, 1887.

First Lieut. Wm. N. Suter, Asst. Surgeon, designated as medical officer for the Rifle Camp at Creedmoor, N. Y., July 5, 1887. S. O. 124, Div. Atlantic, June 21, 1887.

United States Marine Hospital Service for the week ended June 25, 1887:

Guitéras, John, Passed Asst. Surgeon, detailed for temporary duty at Key West, Fla., June 23, 1887.

Wasdin, Eugene, Passed Asst. Surgeon, relieved from duty at Marine Hospital, New York, N. Y.; ordered to Marine Hospital, Chicago, Ill., June 23, 1887.

Norman, Seaton, Asst. Surgeon, to proceed to Charleston, S. C., for temporary duty, June 23, 1887.

Heath, F. C., Asst. Surgeon, relieved from duty at Chicago, Ill., June 23, 1887.

ORIGINAL DEPARTMENT.

LECTURE.

THE EXTERNAL TREATMENT OF PULMONARY CONSUMPTION.

A LECTURE DELIVERED AT THE PHILADELPHIA
POLYCLINIC, BY THOS. J. MAYS, M.D.,
Professor (Adjunct) of Diseases of the Chest in the Phila-
delphia Polyclinic.

Much has lately been said in regard to the treatment of pulmonary consumption by gaseous enemata, by inhalation of medicated vapors, and by compressed and rarefied air; and, however valuable all these methods may be, it must be confessed that their principal value lies in their power to disinfect the catarrhal products in the bronchial tubes, and in such cavities as may be in communication with these tubes; and that they have but very little, if any, decided influence on the solidified portion of the lung—the objective point of all treatment in the disease. It is true that they frequently dry up the secretions, and improve the respiratory function around the seat of infiltration, but this, the citadel of the disease, they leave practically untouched. The failure of these methods to act favorably is due to the fact that neither the blood vessels nor the bronchi—the channels through which the medicaments are conveyed—have, in most instances, any communication with the central seat of infiltration, being occluded by pressure of the catarrhal accumulation incidental to the disease.

We have here, then, in the general majority of instances in this disease, a condition which is a deposit of inflammatory

products in the lung, differing essentially in no wise from a similar deposit in any other part of the body; and it is very natural to suppose that that which does good in the one condition will also be useful in the other. You know as well as I can tell you that the application of moist heat and of passive motion are of inestimable value in producing reabsorption of chronic inflammatory deposits in joints and in other parts of the body—usually the result of injury; and in keeping with this idea, I have for a number of years been in the habit of applying hot flaxseed meal poultices, as well as friction, to the chest in such affections, and I believe with the most gratifying results. According to my view these external applications have the power of increasing the circulatory, the lymphatic, and the cellular activity of the circumference of the infiltrated lung tissue, and, by their operation on the surroundings of the diseased centre, they gradually reduce and remove the consolidation.

First, as to the manner of making and of applying a poultice. The flaxseed meal is boiled and spread three-quarters of an inch thick between two pieces of flannel cut in the shape of a jacket, which is well fitted to the top, front and back of apex, as well as to the anterior and posterior aspects of the affected lung. It is then adjusted to the chest, and the outside well covered with oiled silk or oiled muslin. It must be changed every two or three hours, or sooner if it becomes cool. If it is made properly, it will remain warm for three hours. This process is to be continued from morning until night, when the poultice is taken off, and the chest is well wrapped with woolen

flannel for the night, in order to avoid a sudden disturbance of bodily temperature during the sleeping hours. The next morning the same programme is begun, and it is continued in the same way for at least three weeks, or as much longer as is necessary. It is much more expedient to poultice during the day only, and allow the patient to rest during the night. After the patient has been poulticed for five or eight days a change in the physical signs begins to manifest itself. Where previously there was heard nothing but a roughened or bronchial breathing, subcrepitation, probably crepitation, and mucous râles show themselves, leading one to suspect that the disease is advancing instead of improving. Subsequent experience teaches, however, that these superadded signs are due to the process of resolution which is taking place. The patient experiences greater freedom in breathing, his cough becomes easier, and his expectoration is looser, and at the end of the prescribed time there is usually an improvement in his general condition.

In addition to the application of moist heat, I very frequently employ local or general massage once or twice a day. This has undoubtedly the power of assisting the former method in removing the intra-alveolar material.

Now the case before you to-day, like many others which you have seen in this institution before, has been principally treated by the external method. You will recollect that his history when he first came under observation in March 3d, 1887, was as follows: His age is 31, married, and a weaver by trade. He said he had pleurisy eight months ago, since which time he is suffering from cough, expectoration, much hoarseness, constant dyspnoea, had no hæmoptysis, but his sputum is occasionally blood-streaked. He is losing flesh, has night-sweats, poor appetite and coated tongue.

Physical signs.—Right side: Dullness in apex, extending to second rib in front, and to spine of scapula behind, crepitant and sibilant râles associated with bronchial respiration in anterior aspect of apex over area of dullness, while from here down to base, mucous râles. Left side: Mucous râles distributed over anterior surface of lung. From this date to the following 7th of April, he was treated with the sulphuretted hydrogen enemata twice a day. At the end of this time he felt no better, his appetite was poor, and the physical signs were the same as at the first examination. On this day the poultice and hypophosphites were substituted for the gaseous injections, and after a due course

of poulticing he improved in every respect. His appetite is good, the dyspnoea much less, and he gained in weight. Physical examination to-day, four weeks after beginning of external treatment, shows that the dullness is nearly gone, and the chest râles are very few. This case, while not entirely well, is still interesting from several points of view. It shows how much can be done with well regulated and persistent treatment. If the case is well managed during this preliminary period, and advantage is taken of the improved condition of the appetite, which almost invariably follows, and if these efforts of nature are still further supplemented by appropriate internal treatment, such as giving cod liver oil, the hypophosphites, good nutritious food, compressed and rarefied air, the gaseous enemata, etc., pulmonary consumption becomes as amenable to treatment as any other disease. In the course of two or three months this patient will undoubtedly recover his health as fully as this second case did which I shall bring before you to-day.

The patient aged 35, is the wife of a laboring man, and came under observation December 5th, 1884. She then had a severe and constant cough, yellow, blood-streaked expectoration, which began the previous August. She also had hæmoptysis, poor appetite, night sweats, and was losing flesh. Besides she had a bad family history, her father having died of phthisis. She was treated with tonics, among which were the hypophosphites, iron, quinine, cod liver oil, without any improvement until the middle of the following January, when the flaxseed poultice was applied to her chest, at which time she showed the following physical signs: Dullness and increased vocal fremitus and resonance over right apex, no crepitation, but bronchial respiration over same region posteriorly and mucous râles anteriorly. After being poulticed for one week she breathed more free, and coughed and expectorated less. The record shows that at this time there were (what is frequently experienced during the early period of poulticing) heard over the posterior area of dullness, some moist râles. On February 4th the examination showed that dullness persisted, but that all the moist râles had vanished, except a sharp click during expiration, which was heard behind over affected area. The following April she had recovered so far as to be able to resume her household duties. Since then she gave birth to a fine boy, and as she stands before you to-day, you will find on examining her chest that there is not a single landmark remaining of her former

disease, except probably a slightly roughened respiration.

This external plan of treating pulmonary consumption and other chronic inflammatory diseases of the chest I have had under trial for nearly half a score of years, and it is not only of great practical importance on account of its efficiency, but also on account of the economy which can be practised in regard to giving medicine by the stomach. The digestive organs always deserve great consideration in the treatment of chest diseases, and the less they are utilized for administering medicines, and the more for the purpose of feeding the patient, the greater will the benefits be which accrue to the latter.

COMMUNICATIONS.

SOME OLD-TIME PRESCRIPTIONS.

BY HARRISON ALLEN, M. D.,

Emeritus Professor of Physiology in the University of Pennsylvania.

A short time ago a practitioner of some fifteen years' experience told me that he supposed that he treated very few diseases in the same way as he did when he began his practice. He thought his results were no better now than then. Under attempts to grow and improve on our method in practice, it is an open question if we always change for the better. We certainly have writers of eminence who declare that the number of drugs actually needed in the practice of medicine is relatively few. Prof. Samuel D. Gross was in the habit of saying, "Give me quinine, opium, calomel and jalap, and you can throw all the rest of the *Materia Medica* out of the window." I infer what was meant by such an expression was simply that a good workman can handle a few well-selected tools to good advantage and to the exclusion of the rest of his kit.

While we have added to our list from time to time many important remedies, we should take care not to ignore the claims of those which have been tried and not found wanting in the hands of men as able and as experienced as those of our own generation. One can readily imagine such a splendid observer as was Robert T. Graves, were he now to return to his former field of renown in Dublin, practicing precisely the same methods he did nearly fifty years ago; and perhaps, after all, not to be found wanting in results as good as any of his later-day compeers. In addition to the valuable narcotics which have

been introduced since Grave's time, are we to forget the very important recommendation of this writer of uniting antimony and opium for the relief of insomnia where opium alone has failed? This instance is mentioned since it is an example of the happy effect of combining two remedies, each of which aids the other in securing a result which is not attainable by the use of either drug administered separately. Pursuing the same line of reflection, we can claim an advantage in retaining some of the old forms of the combination of drugs, for the reason that it is not at all likely that our efforts to make new combinations of remedies of the same grade is likely to be as useful.

A number of formulæ have become famous by reason of their convenience, safety and efficacy. Let any one endeavor to improve upon Huxham's compound tincture of cinchona, upon compound spirits of lavender, or upon paragoric, and he will find that very many unsatisfactory attempts will be made before he can even approximate in value these universally accepted combinations. While we deprecate any disposition to practice by formulæ, a number of old and tried recipes may be set aside as possessing unchallenged merit.

I propose to call attention to several of such happy combinations which are known to be especially useful. The first I may mention in this connection is a formula recommended by Thomas King Chambers in the Fourth edition of his "Lectures, chiefly Clinical," London, 1865, page 343. I am not sure that this book contains the first written notice of the prescription, but I find no allusion to it in the first edition of this work.

R	Tincturæ ferri sequichloridi	3ij
	Strychniæ hydrochloratis	gr. ½
	Tincturæ digitalis	3j
	Misturæ camphor.	3x

Fiat mistura. Sig. Two tablespoonfuls, twice daily.

It is not alleged that the formula is original with Dr. Chambers. He simply states that he administered an ounce of the mixture twice a day in a case of anæmia in which the eye balls were prominent. The subject of the lecture in which the statement occurs is that of "Prominence of the Eye Balls." Dr. Chambers dwells upon the significance of the form of anæmia seen in young women in whom there is excitement of heart's action, retarded development of the sexual functions, and engorgement of the thyroid gland. The lecture is a most admirable one. It contains a fine description of this form of disease. The remedy acts most happily.

There appears to be no need of changing it; the iron is adapted to the anæmic condition; the strychnia is a tonic to the small blood vessels and to the central nervous system, the digitalis is a heart tonic and the camphor is an anti-spasmodic. The remedy does not interfere with digestion. With watchfulness and care, its use can be persisted in indefinitely. It is not necessary that all the symptoms included in the above category should be present in order that this remedy may prove efficacious. The recognition of a retarded state of development of the ovaries and associated organs, absence of the secondary sexual characters, anæmia, and a thyroid engorgement, is sufficient.

A second formula, perhaps not as elegant as the foregoing, is the following:

R.	Hydrarg. bichlor.....	gr. iv
	Solve in spirit rectif.....	ij
	Decot. Cinchonæ.....	3 ij
	Mel Rosæ.....	
	Tinct. Myrrhæ.....	āā3ij
M.	et. ft. gargarisma.	

This prescription appears in the Institute of Surgery of Sir Charles Bell. As it appears above, it is copied from Dunglison's American Medical Library, 1840, page 352. The formula is reproduced exactly as it is printed, with the exception that for the words hydrarg. oxymurat., hydrarg. bichlor. is substituted. Our authority recommends the combination for ulcerated forms of syphilitic sore throat. I think it would be difficult to improve upon this formula for a mercurial wash in such a condition. In prescribing it the patient should be directed to use a small quantity at a time, and to note its effects; if it prove to be too severe he should add an equal quantity of water to each dose, which might be limited to a tablespoonful. If this prove to be irritating, it may be again diluted until at last it can be easily borne. The patient should be encouraged to use the remedy as far as practicable in the form above given. If he is compelled to begin with the dilutions he can be induced after he is in a measure accustomed to the effects, gradually to return to the original strength of the remedy. This formula was for many years, and probably is yet, a favorite formula in the Philadelphia Hospital. I became familiar with it while serving as resident physician in that institution in 1861. It is surprising how rapidly the symptoms of an ordinary venereal sore-throat subside under its use when the internal administration of anti-syphilitic remedies is at the same time attended to. I have several times substituted other remedies for it (since it is not an ele-

gant preparation), but I have never found anything which can take its place. I also recommend cordially Sir Benjamin Brodie's method of administering bi-chloride of mercury in congenital syphilis, viz.: the exhibition of the drug in the presence of Huxham's tincture.

Striking effects can be procured in rebellious cases of syphilis by ordering Zittmann's decoction. A drawback to its general use is the expense attending its preparation, which appears to be considerable. Doubtless many practitioners of experience recall the name of Zittmann as connected in a shadowy way with the task-work of their student-life. It is well to remember that his preparation is an illustration of the empirical rule that a remedy that will not be absorbed in one form will be readily taken up in another.

It is seen that both Bell and Brodie employ preparations of bark as vehicles for corrosive sublimate. Graves in his Clinical Lectures, (New Sydenham Soc., Edition II, 2) recommends using a decoction of bark to exhibit tincture of capsicum in a stimulating gargle for the chronic hoarseness of growing boys and girls.

In employing an astringent for a gargle we can receive valuable hints in recalling the way in which our seniors introduced (instead of pure tannic acid) a native substance known to contain the acid. As an example of this form may be named the recipe which is known in Philadelphia as Goddard's gargle. In some formulæ books it appears as Gargarismus Granati Compositus. My inquiries respecting the time when this prescription first became popular have not been successful. It is known that Dr. Paul B. Goddard first prescribed it, and that it has been known from his time, viz., from about 1850, under his name. It was the favorite of more than one of Goddard's contemporaries. It was frequently prescribed by the late Dr. Francis Gurney Smith.

The mixture can be used without dilution, or with an equal quantity of water. It appears to present all the features required by an astringent wash to the throat. If increased strength is demanded it is better to direct an agent to be employed topically by the attending physician.

Another preparation, the uses of which can be made to subserve a great number of indications, is Fowler's solution of arsenic.

Small doses of this preparation, say two or three drops twice a day for a period varying from one to six months, produce most gratifying results in those states of impaired health which appear to be due to an inheritance of a phase of malnutrition, and which is so evasive that it is difficult to give it a distinctive name. Local diseases engrafted on such a condition will often resist remedies until arsenic in the form of liquor potassæ arsenitis is employed. Pharyngitis sicca, atrophic nasal catarrh, anæmia accompanying tertiary syphilis, are sometimes greatly improved, indeed to a degree far greater than it has been in my hands possible with any other agents, by these small doses of Fowler's solution.

THE PUPIL IN HEALTH AND DISEASE.

BY W. CHEATHAM, M. D.,

Lecturer on Diseases of Eye, Ear, Throat, and Nose
in the University of Louisville.*

The size of the pupil in health depends upon the intensity of the light, chiefly, the pupil dilating and contracting as long as there is perception of light.

Contraction to light is a reflex motion, the optic nerve being the afferent nerve; and the third nerve the afferent nerve, innervating the sphincter pupillæ. The anatomical investigations of Meynert have shown that between the corpora quadrigemina, and the centre for the third nerve, in the floor of the fourth ventricle, run communicating fibres, which probably enable this reflex to take place. Owing to the semi-decussation of the fibres of the optic chiasm, the stimulant of light, when applied to the eye alone, passes up each tractus with equal power to the corpora quadrigemina of each side by Meynert's fibres to the centre for the third nerve, and then down the pupillary branches to each eye, causing thereby a contraction of the pupil in the non-illuminated eye (consensual contraction), as in its fellow: so, in testing the play of the pupil of a single eye, cover the fellow eye well. It is probable, however, as Lesser points out, that, in addition to this method of bringing about consensual contractions of the pupil, there is a communication direct or indirect between the centres for the third nerve of each side capable of affecting it. In no other way can the fact be explained that consensual contractions of the pupil is

maintained in cases of homologous hemianopsia. If, for instance, there be a lesion of the right tractus opticus giving rise to left hemianopsia, the centre of the left third nerve alone can be primarily stimulated. But as both pupils act, a communication between the centres of the third nerves must exist. Merkel believes "there is a direct anastomosis between these centres."

In addition to the stimulus of light, the pupil-contracting centre is excited by or simultaneously with the effort of accommodation for near vision. This contraction, however, says Swanzy, is much more intimately connected with convergence of the visual lines than with the effort of accommodation. E. H. Weber asserts, "that the pupils do not contract if accommodation be effected without convergence, but that in convergence without accommodation contraction is observed." A patient I had in the office, March 28th, 1887, appears to upset some of these theories. L. B., age 10, had diphtheria January last; three weeks after recovery he discovered he could not read; vision for the distance was perfect, pupils normal in size, and responded readily to light and darkness. On having him look from my operating room to the front door, a distance of about ninety feet, the hall being rather dark, his pupils were widely dilated. On converging and looking at my finger, held ten inches from the eyes, the pupils did not change in size. The little fellow was suffering from paralysis of accommodation. Convergence was perfect; so was the action of the pupils when exposed to light and shade; but the pupils did not contract on convergence, a condition nearly opposite to what is known as the Argyll-Robertson pupil. Aubert, Priestly Smith, Hensen, and Völckers think there is probably in the posterior part of the floor of the third ventricle a common centre for the three actions—convergence, accommodation, and pupil contraction, these centres coming in close succession.

The existence of such a centre has been placed beyond a doubt by Ealis' case of paralysis of convergence and accommodation, and of the associated pupillary contraction.

Dilatation of the pupil is the result of the contraction of the dilatore pupillæ, innervated by the tonic action of the cervical sympathetic.

The dilating fibres originating in the front part of the floor of the aqueduct of Sylvius, pass to a region in the lower cervical and upper dorsal portions of the cord, called the ciliospinal centre; and from thence pass out with the two first dorsal nerves, and by way

* Read before the Kentucky State Medical Society, at Paducah, June 16th, 1887, and specially reported by Dr. W. Y. Howard.

of the rami communicates to the sympathetic in the neck: and thence to the cavernous plexus, Gasserian ganglion, ophthalmic division of the fifth nerve, nasal branch of this division, ganglionic branch of this nerve, ciliary ganglion, there joined by more branches from the cavernous plexus, and from thence by the short ciliary nerves reach the eye. The dilating fibres are of a two-fold nature: muscular and vaso-motor; experiments indicate this, and that the centre for each kind of fibre is different. While light is the only stimulus capable of bringing about a reflex contraction of the pupil, the pupil-dilation centre reacts to other stimuli, such as galvanism applied to the leg, the tickling of a sensitive place in the region of the fifth nerve on the face, shouting loudly in the ear when under the influence of chloroform. The centre is probably in the medulla oblongata; but, as it takes place when the cervical sympathetic is divided, it is evident that all the dilating fibres do not run to the eye by way of the cervical sympathetic. The pupil of the cat dilates in anger, and those of a child when frightened. The pupils of delicate, nervous, excitable people are often much and habitually dilated.

With deep inspiration and expiration the pupil dilates, the result of retention of carbonic acid gas in the blood. It also dilates at the beginning of each labor pain, showing the close association of the two centres. The fifth nerve is supposed by some to have a similar influence on the pupil as the sympathetic; the confusion arises from the fact that the fifth nerve, when divided within the cranium, divides also the sympathetic.

With the action of mydriatics, atropia, duboisin, hyoscyamin, and daturin, eserin, etc., all of us are familiar. When the pupil suddenly dilates under chloroform-narcosis danger, is near.

Now, as to the pupil in disease, myosis. or a contracted pupil, may be caused by a diseased process irritating the pupil, contracting the centre or fibres (irritating myosis), or by one causing paralysis of the pupil-dilating centre or fibres (paralytic myosis), or by combination of both; either cause would produce a medium myosis. A combination of the two would give a maximum myosis. Irritation myosis, according to Lesser, is not usually increased by the stimulus of light, nor on convergence, nor does it diminish in shade. Mydriatics dilate such a pupil widely; myotics contract it ad maximum. In paralytic myosis the pupil reacts well to light and convergence, but does not dilate on application of sensory stimuli or with

co-ordinate motions. Mydriatics dilate such a pupil only partially, while myotics contract it ad maximum.

In maximum myosis every reaction is defective, strong mydriatics alone producing medium dilatation. Irritation myosis is found in the early stages at least of all inflammatory affections of the brain and its meninges, in simple tubercular, and cerebro spinal meningitis. When in these diseases the medium myosis gives place to mydriasis, the change is a serious prognostic sign, indicating the stage of depression, with paralysis of the third nerve. In cerebral apoplexy, according to Berthold, the pupil is at first contracted, which makes this a point of differential diagnosis between apoplexy and embolism, in which the pupil is not changed. In the early stages of intracranial tumors, situated at the origin of the third nerve or in its course, at the beginning of a hysterical or an epileptic attack; in tobacco amblyopia, probably from stimulation of the pupil-contracting centre by nicotin; in persons following certain trades, watch-makers, jewellers, etc.; as a reflex action in ciliary neurosis, consequently in many diseased conditions of those parts of the eye supplied by the fifth nerve. Paralytic neurosis occurs in spinal lesions above the dorsal vertebrae, such as injuries and inflammations, and especially the chronic form. The contracting pupil occurring in gray degeneration of the posterior columns of the spinal cord has long been known as spinal myosis. In the simple form of this myosis the pupil has but a medium contraction, and reacts to both light and convergence. This condition is found in the early stages alone, when the disease has attacked the cilio-spinal centre, or higher up, as far as the medulla oblongata; later on, when Meynert's fibres become engaged, we have the Argyll-Robertson pupil. The very minute pupil often seen in tabes dorsalis is often due to secondary contractions of the sphincter pupillae. Argyll-Robertson first pointed out that in tabes dorsalis, the pupil although contracted, and responding to light but slightly or not at all, contracts on convergence of the visual axes. He explained this phenomena as being due to paralysis of the cilio-spinal nerves, which he therefore regarded as the nerves supplying the sphincter iridis.

Rachlmann points out that the myosis and the motor phenomenon are not directly connected, for it sometimes happens that pupils which do not react to light and do not contract on convergence, are not habitually contracted, and may be even somewhat dilated. The two symptoms are no doubt

often present together in tabes. The myosis is a sign, and an important one, of disease of the posterior columns; while the defective reaction to light, with retained contraction on convergence, indicates some disease at some distance from the spinal cord, namely, in Meynert's fibres; and this is probably the correct explanation of the Argyll-Robertson symptom. Rachlmann and Drown regard myosis as one of the cohort symptoms of tabes, while Vincent does not.

Paralytic myosis is found in general paralysis of the insane. In acute mania the pupil is usually much dilated, and when the mydriasis is changed from myosis, approaching general paralysis may be prognosticated. Myosis following an irritation-mydriasis is also found in myelitis of the cervical portion of the cord.

In bulbar paralysis, if paralytic myosis occurs, the disease is probably complicated with progressive muscular atrophy, or with sclerosis of the brain and spinal cord. Myosis may also be due to paralysis of the cervical sympathetic, the result of pressure of an aneurism, or enlarged lymphatic gland. In apoplexy of the pons varolii myosis is present.

Uthoff found reflex immobility of the pupil, combined with preservation of reaction on convergence in 136 among 166 cases, under the following circumstances: In tables of 92 cases, 67 per cent. of all cases, the pupils were of unequal width in one-fourth of all cases; unilateral paralysis of accommodation in only five cases.

In dementia paralytica in 12 cases.

“ syphilis in 11 cases.

“ other cerebral affections in 8 cases.

“ multiple sclerosis in 2 cases.

“ railway spine in 2 cases.

“ injury of the head in 1 case.

“ congenital feeble-mindedness in 1 case.

“ abuse of tobacco in 1 case.

“ hystero-epilepsy in 1 case.

“ hemianæsthesia dextra in 1 case.

No cause assignable in 3 cases.

Reflex immobility of the pupil, without reaction on convergence was found in 30 cases, as follows:

In syphilis in 8 cases.

“ tabes in 3 cases.

“ progressive paralysis in 3 cases.

“ injury in 2 cases.

“ cold in 1 case.

“ beginning tuberculosis of the brain in 1 case.

In tumor cerebri in 1 case.

No cause assignable in 12 cases.

Mydriasis may be caused by a diseased

process, giving rise to irritation of the pupil, dilating centre fibres, or by paralysis of the pupil contracting centre, or fibres. The former is characterized by a moderately dilated pupil, contracting somewhat to light and in convergence, but not dilating on sensory stimuli, easily dilated ad maximum by mydriatics, but with difficulty contracted ad maximum by myotics. The latter is called paralytic mydriasis, and in all there is a moderately dilated pupil reacting to sensory stimuli. The reaction to light and on convergence varies according to the seat of the lesion. If the latter lie between the iris and pupil-contracting centre the direct and consensual reaction to light is wanting, as also the associated motion on convergence of the visual lines. But if the lesion lie between the retina and the pupil-contracting centre, the direct contraction to light is *wanting*, but the consensual contraction and that on convergence is retained. In either case the pupil can be dilated ad maximum by mydriatics, but not contracted more than medium by myotics. Irritation of the pupil-dilating centre and paralysis of the pupil-contracting centre existing simultaneously give rise to maximum mydriasis.” Irritation mydriasis occurs in hyperæmia of the cervical portion of the spinal cord, spinal meningitis and the early stages of the new growths in the cervical portion of the cord, cases of intracranial tumors and other diseases causing high intracranial pressure, according to Rachlmann, although according to Lesser, these may also rise to paralytic mydriasis, in spinal irritation of anæmic people, often severe illness. As a premonitory sign of tabes dorsalis, in cases of intestinal worms, or other forms of intestinal irritation, in acute mania, melancholia, or progressive paralysis of the insane, we often note the unilateral form with myosis in the other eye. Unilateral mydriasis occurring in short intervals, now in one eye now in the other is, according to Von Graefe, a premonitory sign of mental derangements. Paralytic mydriasis may be due to paralysis of the pupil-contracting centre, or occur as a result of the stimulus not being conducted from the retina to the centre. It may be found under the former circumstances, sometimes in progressive paralysis, when at first there was myosis. In various diseased processes at the base of the brain, affecting the centres of the third nerve. In a later stage of thrombosis of the cavernous sinus in orbital processes which cause pressure on the ciliary nerves, in glaucoma in cases of intra-ocular tumors which have attained a certain size.

A FEW FACTS ABOUT INJURIES OF BASE-BALL PLAYERS.

BY A. H. P. LEUF, M. D., OF PHILADELPHIA.

Late Pathologist to St. Mary's General Hospital and
Surgeon of the Southern Hospital and
Dispensary, Brooklyn.

As a systematic discussion of the injuries of base-ball players would consume too much time and space for a single paper, I shall, in this one, only call attention briefly to some of the peculiarities of this class of injuries, as well as to what a player must bear as an ordinary every-day matter.

The Ball.

In the first place, a regulation base-ball measures nine inches in circumference and weighs five ounces. It is composed of woolen yarn firmly wound around a one ounce solid rubber sphere. The whole ball is covered with two pieces of horse-hide, and is then wrapped in tissue paper and tin foil, and sealed up in a stamped box. The price is \$1.25 and \$1.50 each. Two or more are used in every game, lasting about two hours. The ball seems almost as hard as wood.

Momentum of the Ball.

The ball is thrown most of the time with great force. The pitcher, who is constantly sending it towards the batsman, to be struck at, causes it to go along with the greatest possible speed. Under such circumstances, it frequently traverses fifty feet in one second. The man who catches the ball wears heavy gloves; the one upon the left hand often having thick sole leather finger-tips. A pitched ball also has a well marked gyration in either direction upon a horizontal, vertical, or oblique axis. This makes the catcher's work very hard. He is likely to be injured, especially when the batsman in hitting the ball, causes it to continue onward behind him with increased momentum and slightly deflected from its course the moment it is struck by the bat. When the catcher is up behind the bat, he runs a great risk of injury from these deflected balls or "foul tips," as they are called.

The other players who throw the ball from base to base, or "home" to prevent a run being scored, throw with all their might to get it to the desired place before the runner. A good thrower can throw a ball 300 feet, though it has been thrown over 400 feet. Balls batted up into the air are called "fly balls," and, if batted very high, have a great momentum when they fall into the fielder's hands.

The impact of the ball upon the player's hands usually is something unimaginable till seen or experienced. A novice would have a crippled hand for many days if he was foolhardy enough to attempt catching a swiftly thrown ball, so terrific is the speed and impact.

Protection of Players.

The catcher, who stands behind the bat, would be in the most dangerous position if not protected. To guard against accidents, so far as it is possible, he is provided with the heavy gloves already mentioned. They are padded in the palm, and open at the back so as not to be too warm. The right hand glove has no fingers so that the ball may be grasped and thrown with swiftness and accuracy. His additional protection consists in a heavy mask made of the best steel wire of about the size of telegraph wire. This is held against the face by dog leather straps resting against the forehead and chin, and an elastic band which passes around the head. I have a number of times seen these heavy masks beaten out of shape while on a player, by being struck by a foul tip. But yesterday I saw one knocked off the catcher's face fully twelve feet over his head into the air. If the catcher is a wise and sensible man—and most of them are now-a-days—he wears an inflated rubber chest and belly pad, secured to the body by a neck and waist strap.

The hardest blows, kicks, or swiftest thrown balls may be allowed to strike this pad, while on a player, with impunity, and that, too, right over the solar plexus. It does not cause any inconvenience.

Catchers' gloves are almost always worn by the first-baseman, to whom many balls are thrown as swiftly as a player can send them, so as to put out the batsman who has hit the ball and is running to first base. The other players as a rule have no protection other than their wits and bare hands. If one has a sore or tender hand, he may wear a glove. The pitcher, all things considered, is in most danger, as he stands immediately in front of and within fifty feet of the batsman. A sharp hit "line ball" may strike him anywhere before he can tell where it has gone. Only yesterday I saw a pitcher just have time to throw up his hands and save his face from being badly hurt. No one, I believe, saw the ball, but heard the crack of the bat striking it and immediately afterwards the smack as it came against the pitcher's hands. Thus while the catcher naturally occupies a position of great danger, the pitcher's is actually more so, because he is without any guard whatever.

The Way to Catch and the Way Not to Catch.

Scientific catching is easily understood, but often difficult to learn. It is necessary that the hands should recede with the advancing ball, thus lessening the force of the impact and preventing bruising. This cannot, however, be avoided in catching very swiftly moving balls, though it can be modified. Again, it is very important to have the edges of the hand facing the coming ball, instead of pointing the tips of the fingers towards it. All one's attention should be directed towards gauging the ball as it arrives, whether it be from above, on a line, or bounding or rolling upon the ground, and the hands should never be held in position to receive the ball till it is actually time to do so. Care must always be taken to shade the eyes from the sun, and the fear of being injured must never interfere with good judgment.

The wrong way to catch is to push the hands against the advancing ball, or to hold them stiffly. Holding the hands with the fingers directed toward the ball is bad, as it often causes severe injuries. By holding the hands ready for the ball before it is necessary, one is more apt to get them in an awkward position in case the ball should take an unexpected course, for instance, as caused by a gust of wind, by curving or by deflection in bounding or rolling upon an uneven ground. Many injuries have been sustained because of the sudden flashing of sun into the eyes, causing sudden loss of sight of the ball, or at least of perspective or distance. A man should never attempt to field a ball he is afraid of, as he is very apt to be hurt if he does.

The Injuries of Ball Players.

Those which arise from pitching, I have touched upon at length in another paper which will appear about the same time as this, or a little later. I shall therefore speak of the others. Those most commonly sustained are subluxations of fingers; complete dislocations of the same, either simple or compound; clean cut or contused wounds; bruises of any part of the body from thrown balls; abrasions from sliding while on a "dead run;" "stone bruises;" and fractures and dislocations of the large and small bones of the extremities.

Injuries to the fingers and hands are almost invariably due to a habit of catching the wrong way, or to carelessness. I saw one man who had a double dislocation of the right index finger. The distal phalanx was turned backwards, while the middle phalanx was turned toward the middle finger. A

fellow-player took hold of the proffered crooked finger and promptly pulled it straight, and the game went on with the injured man at his post as though nothing had happened, and with only 10 or 15 seconds interruption. He continued playing nearly every day and his finger, while at first swollen and somewhat tender if hit hard, recovered itself completely.

Another man, while attempting to catch a high fly ball on a run, caught the sun in his eye, lost sight of the ball for a moment, and had it fall between his upraised hands upon his right eyebrow. It made a clean cut that bled profusely and required four horse-hair stitches. There was nothing antiseptic about the sewing and dressing of the wound, and yet the stitches were removed on the fifth day and union was perfect. The patient was a physician, and, without any surgical dressing whatever, went about his professional work as usual the day after the injury.

Still another player had the web between the little and ring fingers of his right hand torn to the depth of three-quarters of an inch by a line-hit ball. It was stuck together with sticking plaster after the bleeding had ceased; he continued playing, and, at the end of the week, it had healed with a minimum scar.

Similar instances could be cited by the score, but it is not necessary. They nearly all give rise to little trouble and leave no bad after effects.

Subluxations of finger joints are common. They cause periosteal thickening, and even inflammation and hypertrophy of bone if not properly treated. All such thickenings, though not beautiful, make the joint stronger. They are useful but not ornamental.

I have a finger on my right hand which presents one of these thickenings. It was derived from five successive injuries received at the same place within one week while I was serving an apprenticeship to the game. It was treated *secundum artem*. The result was bad. Every one of the other nine fingers have been injured since, and some as badly as the specimen mentioned, but to-day they are perfectly normal. They were not treated according to the "best surgical methods," but according to base-ball custom. This consisted in continuing to play, and, whenever opportunity offered, either in the street, in the office, on cars, or upon the field, in firmly grasping the finger at about the middle and rubbing towards its tip. If continued a little while, the swelling, stiffness and soreness diminishes and after some weeks it is entirely gone.

The bruises of the body due to being hit, with pitched, batted, or thrown balls, are extremely painful at the moment and the pain usually lasts about half or one minute. Then it rapidly diminishes, until little discomfort is felt. Slight tenderness may remain for a day or two, rarely more; and discolorations, if present, continue the usual time.

When one is hit upon the back with a swiftly pitched ball, it is felt more as if it struck the inner side of the anterior wall of the chest, and the player's two hands are often quickly brought up against the front of the chest opposite the point in the back hit by the ball. This shows that the ribs transmit the force of the ball. The pain, as a rule, is of very short duration, but severe while it lasts, sometimes felling a player to the ground.

A pitched ball once struck the top of my head with sufficient force to bound off directly upwards a distance of fully 60 feet. It dropped within less than 10 feet of where I stood. There was no pain in the sensation, I simply felt it, that was all. Five minutes later, the place which had been struck could no longer be identified by pressure and percussion. There was no tenderness. This goes to show that what are apparently very serious accidents, really become laughable incidents of the game.

The proportion between the apparent risks of ball players and the actual number of serious injuries sustained, is marvelously small. Last year an umpire was instantly killed by being hit upon the chest with a foul tip. This year, a similar tip struck the pugilist Sullivan between the eyes and he was not even dazed, but pronounced it only equal to the blow of an inferior member of his own kind.

Compound dislocations are occasionally sustained; in fact, they are reported from some section of the country almost every week, but the proportions of such casualties is very small. The few I have seen did remarkably well by being simply pulled in place by other players and bandaged moderately tight. Playing in each instance was continued the very next day, or after a few day's rest at most. Primary union is the rule.

That ball-players have a special immunity, I of course do not claim; but it is evident to me that their injuries are peculiar, and the peculiarity is largely due to the training they get in becoming accustomed to resisting violence which has again and again been proven dangerous to the uninitiated.

To catch a "hot line ball" as soon as one

gets on the field, without any practice since the day before, and with sweaty hands, causes enough pain to set one's teeth on edge, and to make one anathematize base-ball and all its belongings. Let the hands be dry, though, and gradually accustom themselves to the swiftly coming ball, and there will be no pain. In some people the hands remain rather hard and firm, while in others they swell to as much as three times their usual thickness. The fingers also swell. This soft cushion is a wonderful protection against pain. Professional ball-players often have hands as soft as a woman's, especially some catchers and first basemen. In all of these the hands swell during play. This swelling comes on within from a few minutes to half an hour and increases till it reaches its maximum. I have seen it so great that the fingers could not be sufficiently closed to hold the ball. In this respect the hands of ball-players certainly differ from all others. They must in time undergo some radical, functional, and perhaps some structural changes. The physiological processes are more active. Repair after injury must therefore be more rapid and the tendency toward recovery so much the greater.

The Treatment of Base-Ball Injuries.

This is simple. There is one remedy and it is the panacea of the player's physical woes if he be not too lazy to avail himself of it—*hot water*. Nothing else compares with it. Its effects in the relief of pain are almost instantaneous. It is easily applied and inexpensive. To be effective, the water must be as hot as can be borne, and it must be kept so for an hour at a time if possible. The most marked swelling of the hands and severe pain can thus be reduced within twenty minutes. Otherwise it would require hours and be accompanied by some suffering. I have repeatedly observed that nothing will do so much harm to a player as to have him abstain altogether from playing because he has some trivial injury or sore muscles. No other treatment should be attempted for subluxation and simple dislocations without at first liberally using hot water. After this, it is best to surround the injured member with adhesive plaster and to place over all a moderately firm finger-bandage. The player may then continue playing if he choose. In cases of much effusion and tenderness of several weeks' standing, it is well to use moderate galvanism. If it is doing good, the patient will feel much the same sense of relief that he experiences with the use of hot water. The stroking of the finger, as already mentioned, is never to be neglected.

Lack of space forbids a more extended notice of these injuries. It is my intention to give more detailed particulars at a later day. But the fact remains that the injuries of ball-players heal more quickly and do less damage than *a priori* reasoning would cause one to suppose; and I believe that this is explained on the ground that the nutrition of the players' hand is much more active than in other people's, and hence tends more to recovery, as we find in children, in whom the nutritive changes are also very active.

240 South Eighth street.

HOSPITAL NOTE.

MEDICAL DISPENSARY OF THE UNIVERSITY OF PENNSYLVANIA.

Reported by M. Howard Fussell, M. D.

Gastric Pain.

The following cases have been selected as types of a class of cases, numerous as they are annoying to the practitioner. The treatment suggested, however, has been quite universally successful, and, though by no means original, deserves recording:

Wm. G., carpenter, aged 41 years. Habits good; always been accustomed to eat much indigestible food. For one and a-half years been suffering from severe epigastric pains; worse after eating; relieved by lying on the back; no vomiting; some flatulence; tongue flabby and coated. On examination there was found much tenderness in the epigastrium. He was put on a pill of $\frac{1}{4}$ gr. silver nitrate and $\frac{1}{2}$ gr. pulv. opii. His bowels were regulated by cascara sagrada. Almost immediately his pain began to subside, tenderness became less marked, and at the end of two weeks he considered himself cured. He received no other drugs except for a short time a mixture of tr. gentian and nitro-muriatic acid. At the present writing he remains well, with still some dyspepsia, but the annoying pain entirely relieved.

Robt. P., merchant, aged 71, married. Good habits. Had always been in the habit of eating cakes and cheese between meals, while attending to his store. For a number of years has had much flatulence after eating, but considered himself well until a year previous to his appearance at Prof. Osler's clinic. Suddenly, in the night, one year before, he was seized with a severe attack of epigastric pain, relieved by morphia; in two or three weeks had a similar attack; neither of these accompanied by vomiting. These at-

tacks were repeated four or five times, when their character suddenly changed. The pain became less marked, but was still present; but now he was attacked by distressing nausea and vertigo. The vertigo was so violent that he would fall. Some of the attacks were accompanied by purging. In the past year he has lost fifty pounds in weight. On examination by Prof. Osler his abdomen was flat, no evident tumor but an unnatural tenseness. A spot of tenderness was found just below the ensiform cartilage. This case was at first regarded as possible gastric cancer; but subsequent developments showed its true nature to be a gastric catarrh with gastralgic attacks. He was put on a powder of bismuth subnit, 10 gr.; soda bicarb., 5 gr.; morph. sulph., $\frac{1}{2}$ gr. In two weeks he had another attack, but the intervals lengthened, and he is now, a year and a-half after the first visit, apparently entirely well.

The treatment of these two cases is that which is followed as a rule in such cases in my room of the dispensary. It is usually successful. The silver and opium are used in the class of cases without marked flatulence, while the above powder is used where flatulence is a marked symptom.

REPORTS OF SOCIETIES.

THE PENNSYLVANIA STATE MEDICAL SOCIETY.

THIRTY-EIGHTH ANNUAL SESSION, BEDFORD SPRINGS, JUNE 29 TO JULY 1, 1887.

Friday, June 29.

The meeting was called to order by Dr. R. Davis, of Wilkesbarre, and prayer was offered by the Rev. E. N. Kremer, after which Dr. S. H. GUMP, of Bedford, made an interesting ADDRESS OF WELCOME. After the transaction of business, Dr. J. B. MURDOCK, of Pittsburg, delivered the *Address on Surgery*, taking for his subject: 'amputations through the foot; advocating the employment of Chopart's operation, and supporting the general principle that amputations should be made as far from the trunk as possible. The address contained the history of a case a man who had both of his feet frozen, and on whom Dr. Murdoch performed Chopart's operation for the consequent death of the ends of the feet. Both feet were operated upon at the same time. The result was unusually good, as the patient, after this double mutilation was able to go about with only one cane, walking erect, and being able to do a certain amount of walking without a cane.

DR. CHARLES S. TURNBULL, of Philadelphia, read the *Address on Ophthalmology*. This address contained many points of interest for the general practitioner, and it will be published, together with the diagrams with which it was illustrated, in an early issue of the REPORTER.

DR. CHARLES W. DULLES, of Philadelphia, then read his *Report on Hydrophobia* for 1886, reviewing the history of the subject during the year past since last the Society met. Especial attention was paid to the developments and changes in Pasteur's method of preventive inoculation.

DR. JOHN V. SHOEMAKER, of Philadelphia, exhibited, and described the uses of, some "*Medicated plasters for diseases of the skin.*"

DR. HOWARD A. KELLY, of Philadelphia, exhibited a remarkable specimen: a testicle removed from the right labium majus of a woman about 40 years old, who had been married for years. This was a case of transverse hermaphroditism.

In the evening a handsome banquet was given to the visiting members of the profession, and a large number of invited guests, in the dining room of the Bedford Springs Hotel.

Second Day, June 30.

DR. FRANK WOODBURY, of Philadelphia, read the *Address on Practice of Medicine*, advocating a form of exercise for combatting a tendency to phthisis.

DR. TRAILL GREEN, of Easton, then read a paper on *Palatable Therapeutics*, in which he drew upon his extensive experience for many interesting and instructive facts.

DR. GEORGE STUBBS, of Philadelphia, read a paper on *Iodoform in Surgery*.

The next paper on the programme was one by Dr. S. Solis-Cohen, on *Modern Methods in the Treatment of Pulmonary Consumption*.

In this paper Dr. Cohen spoke favorably of the results which may be obtained by Bergeon's method, but avoided exaggerated commendation.

DR. JOHN H. PACKARD, of Philadelphia, then described a case of *Right Inguinal Colotomy*, performed for chronic obstruction of the bowels, after an operation on the left loin had failed to disclose the location of the colon. The inguinal colotomy accomplished its objects in relieving the patient.

DR. THOMAS J. MAYS read a paper on the *Salient Points in the Treatment of Pulmo-*

nary Consumption. In this paper much stress was laid upon the advisability of early treatment, especially hygienic, in the treatment of phthisis, and some very remarkable results, in the practice of the author were cited.

An interesting discussion followed, which was participated in by Drs. J. H. Musser, Vogler, Traill Green, James Tyson, S. Solis-Cohen, and others. This discussion indicated the general opinion that consumption is a disease largely dependent upon a weak system and one liable to give way under strain. The way to prolong life is to begin at the earliest moment in life to fortify the subject of a tendency to phthisis against its outbreak. To this end good food and plenty of it, good air and exercise, and comparatively little medication are the most useful measures to be recommended.

When phthisis is fully established the patient can be much relieved; and the physician is bound to use every means to restrain the processes of fever, and sweating and profuse expectoration, which are available. Among these measures antipyretics have a certain value, and even Bergeon's method is of service.

The discussion also brought out the general opinion that phthisis pulmonalis is sometimes cured, and that it sometimes proceeds to a spontaneous cure.

DR. EDWARD JACKSON, of Philadelphia, read a paper entitled "*When and how to use Mydratics in the Eye.*"

In the evening the PRESIDENT, DR. R. DAVIS, of Wilkes-Barre, delivered the *Annual Address*.

In this address a conservative but hopeful appreciation of the value of medication was given, and useful suggestions offered as to what can be expected, and ought to be expected, from the use of drugs.

Third Day, July 1.

The programme for the third day included the *Address on Mental Disorders*, by DR. J. Z. GERHARD, of Harrisburg; a paper on *Expectorants in Pulmonary Diseases*, by DR. J. C. LANGE, of Pittsburg, and others.

The reading of a number of papers set down for the day was prevented by the departure of many of the delegates whose duties compelled their return before the session was finally concluded.

The following is the list of officers selected for the coming year:

President—Dr. R. J. Levis, Philadelphia.

First Vice-President—Dr. J. T. Ullom, Greene Co.

Second Vice-President—J. L. Seybert, Centre Co.

Third Vice-President—W. T. Hughes, Bedford Co.

Fourth Vice-President—A. M. Cooper, Bucks Co.

Permanent Secretary—Dr. W. B. Atkinson, Philadelphia.

Recording Secretary—Dr. Charles W. Dulles, Philadelphia.

Corresponding Secretary—Dr. J. H. Musser, Philadelphia.

Treasurer—Dr. O. H. Allis, Phila.

Committee on Publication.

Dr. W. H. Parish, Phila., *Chairman.*

G. W. Guthrie, Wilkesbarre.

L. H. Gump, Bedford.

Edward Jackson, Philadelphia.

Judicial Council—Dr. Traill Green, Easton.

“ Bishop, Harrisburg.

“ A. M. Miller, “

Place of next Meeting—Philadelphia.

Time of next Meeting—First Monday in June, 1888.

Chairman of Committee of Arrangements—Dr. John H. Packard.

Before adjourning, the Society voted an appropriation of one thousand dollars to the Ninth International Medical Congress.

ASSOCIATION OF MEDICAL SUPERINTENDENTS OF AMERICAN INSTITUTIONS FOR THE INSANE.

THE FORTY-FIRST MEETING OF THE ASSOCIATION WAS HELD IN DETROIT, MICH., ON JUNE 14TH, 15TH AND 16TH.

First Day—June 14th.

After the customary address of welcome, and a reply by the President, Dr. Henry A. Buttolph, of New Jersey, the scientific proceedings were opened.

DR. FOSTER PRATT, of Kalamazoo, on behalf of the Boards of Trustees of Michigan Asylums for the insane, read a paper on “The Asylum Methods of Michigan.” He went into an extended analysis of the nativity of the insane of the State, and showed that by far the larger percentage of insane, deaf, dumb and blind in Michigan are of foreign birth or descent.

The Nominating Committee reported the following names:

For President—Eugene Grisson, of North Carolina.

For Vice President—John B. Chapin, of Pennsylvania.

For Secretary and Treasurer—John Curwen, of Warren, Pa.

All the nominees were unanimously elected.

In the afternoon the retiring president, DR. H. A. BUTTOLPH, read his address, the topic being, “Insanity or Mental Derangement, with remarks on its nature, causes, classification, pathology and symptomatic forms.”

DR. DANIEL CLARKE, of Toronto read “A Psycho-Medical History of Louis Riel,” which was of great interest. Riel's mental instability was clearly shown, and his visionary schemes of becoming the head of some great religious movement dwelt upon.

The speaker detailed his own experiences with Riel in 1885, and said that Riel, while manifestly insane on certain subjects, rebelled against the idea that he was insane: he had rather die as a deliverer than live as a lunatic. Dr. Clarke considered that up to the time of the first rebellion Riel was intermittently insane, but after that time he was continually demented.

Second Day—June 15th.

DR. W. B. FLETCHER read a paper on “Trephining in Insanity Caused by Injury to Skull.” He cited a number of cases in which insanity had been induced by injury to the skull, and had been cured by trephining. Traumatic insanity does not always occur at the time of the injury, and is very frequently preceded by epileptic fits.

DR. CROSS exhibited a portion of a skull, showing that in that case the external depression was not opposite the protrusion on the inner table of the skull.

DR. EVARTS, of Cincinnati, reviewed the paper briefly, and took the ground that there should be no hesitation in resorting to trephining; for if the patient dies he is no loss, while if the operation should be successful another human being is saved to the world.

DR. DRAPER, of Vermont, said he hoped Dr. Evarts did not mean to say that an insane person's life was not worth saving.

DR. EVARTS answered that he meant that the life of a person hopelessly insane was not worth saving.

DR. ROBERTS, of North Carolina, raised the question as to whether it was desirable to trephine in cases of long standing.

DR. FLETCHER said that the best results he had attained had been in two cases of very long standing.

DR. CAMPBELL, of Tennessee, cited a case of perfect dementia of three years' standing, which was cured by trephining.

DR. C. K. CLARKE, of Kingston, Ontario, read a paper on "Goitre and Insanity." At Rockwood Asylum, Kingston, he found a large number of goitrous patients and one goitrous attendant. He found that the goitrous patients were of long residence, and that the 288 patients who were the victims of the disease had come from all parts of the Dominion, and that the size of the goitre was in proportion to the length of residence. In the Hamilton Asylum the same goitrous conditions exist, and it is possible that local influences may have much to do with them, though it is evident that the insane are much more liable to the disease than healthy sane persons.

DR. FLETCHER, of Indianapolis, said there were in his asylum nine well-developed cases of goitre, all of them in people of foreign birth and two of them sisters.

Afternoon Session.

At 3.20 the association reassembled, and DR. W. B. GOLDSMITH, of Providence, R. I., read a paper on "Communicated Insanity," taking the ground that it is not likely or even scarcely possible for insanity to be communicated. The literature of the subject is very limited, and confined principally to French journals. The epidemics of insanity, especially in the middle ages, can be more properly called simultaneous insanity than communicated insanity. It may be communicated under exceptional cases, but it is rare, and more common among women than men.

DR. H. M. HURD, of Pontiac, gave an instance of three families in Genesee county connected with each other, who all became crazy on the subject of witchcraft.

DR. GILMAN gave a case in his experience where a woman, whose husband had become insane, appeared to share his delusion; but as soon as he was taken away she became perfectly sane, showing that her mind was only a reflex of his.

DR. BUTLER, of Hartford, Conn., was inclined to doubt the possibility of communicating insanity, though he could see good reason for one mind to be the reflex of another without any morbid change. He could also see why, under the same conditions, insanity might develop in two or more persons.

The discussion was somewhat extended, and a number of cases of simultaneous or "communicated insanity" were cited.

DR. B. D. EASTMAN, of Kansas, next read a paper on "Mesmerism vs. Fascination," and instanced a case in which a very suc-

cessful mesmerist was accused of committing a crime upon the person of a lady whom he had subjected to his mesmeric influence, and who repeatedly visited him at his room at the hotel, not because she wanted to, but because his influence had forced her to do so. The doctor on the trial testified that the girl was not drawn to the hotel by mesmeric influence, but by personal fascination. The charge of crime was not sustained.

Third Day—June 16th.

The day was devoted to relaxation, and Fortress Monroe was selected as the place for the next meeting.

Fourth Day—June 17th.

DR. EDW. COWLES, of Somerville, Mass., read a paper on "Nursing Reform for the Insane." He had established two training schools for nurses, and had made the subject one of exhaustive study. In 1873 the trial was made for the first time in American hospitals of trained nurses, as an experiment, but now they are found in almost every hospital. The two training schools in Boston have graduated 300 nurses, of whom 242 are now actively engaged.

The next matter which came before the association was the discussion of the question, "Are Dipsomania, Kleptomania, Pyromania, etc., valid forms of mental disease? Do uncontrollable impulses to use stimulants, to steal, to burn, etc., develop independently of other evidences of insanity?"

DR. O. EVARTS, of Cincinnati, took the ground that these manias are valid forms of insanity. He had great experience with alleged dipsomaniacs. They are victims of uncontrollable desires. They are insane, but there are no instances of uncontrollable desire for stimulants preceding personal experimentation with intoxicants. The speaker had never seen such a person who did not have other mental weaknesses. There are two classes of inebriates. The one class includes a large class of habitual drunkards, and the other what are known as periodical drunkards. It is among this latter class that many claimed dipsomaniacs are found, but the speaker said he could not see any reason for the claim. He had had little experience with kleptomaniacs, but he did not believe them insane. He thought they were imperfectly developed morally, and that they do not steal, but simply reach for what they see, not because they want it, but from an uncontrollable disposition to acquire property. They sometimes are insane, but there are other evidences of this mental disease than the mere act of appropriating the property

of others. As to pyromaniacs, he had never seen one, but he had seen mad men and women who would burn anything they could, and who would set fire to their own clothes, but they were in no instance pyromaniacs, having an insane desire to burn, and sane on all other subjects.

At the afternoon session, a discussion on "The Best Method of Providing for the Chronic Insane" was opened by DR. P. M. WISE, of the asylum at Willard, N. Y. He objected to the arbitrary classification of the insane into two classes, owing to the uncertainty of determining when a state of insanity becomes chronic or incurable. He favored the mixed asylum as the best system. He quoted the family system as practiced in Massachusetts, which he did not approve

and the difficulties of which he pointed out, especially the danger of the insane being abused and made drudges of by the families with whom they might be placed.

DR. FOSTER PRATT said that the experience at Kalamazoo was that patients who were well enough to be removed from the asylum were placed in cottages so remote that they could not see the asylum, and that they did the best. Fifty per cent. of the patients at Kalamazoo are chronic, and of these (400 in all) 250 can be relied upon almost every day for some labor. These will work in tailoring, shoemaking, farming and other industries, and will save to the institution \$2,500 a year in cash. He also showed how great savings were made by the colony system.

EDITORIAL DEPARTMENT.

PERISCOPE.

Martineau's New Remedy for Diabetes.

Martineau's new anti-diabetic remedy, which is now being called for by physicians and druggists, is an artificial lithiated arsenical water. Martineau claims extraordinary results from this water, recording 67 cures out of 70 cases, *i.e.*, 96 per cent. The mode of preparing and of prescribing this remedy is as follows: A syphon bottle holding about a litre, (one quart), is taken; into this is put a powder consisting of 20 centigrammes, or about three grains of carbonate of lithia. A tablespoonful is then added of the following solution:

Take of distilled water 500 grammes (1 pint 5 drachms).

Arsenate of soda 20 centigrammes, (about 3 grains).

M. Dissolve.

The syphon bottle is then charged with carbonic acid water from a soda fountain, and is ready for use. The patient makes this water his principal beverage, taking the whole quantity in about equally divided doses with his meals. The bottle must be freshly charged every morning. Martineau allows the patient to take with the water a little wine. The diet is not modified, except that a certain amount of reserve is enjoined in the use of starchy foods, fruits, and sugar.

Martineau claims to have learned this mode of treatment from Professor Rouget twelve years ago. When the diabetes is treated by lithia alone, or by arsenic alone, the result is not the same. Many of the natural mineral waters, as Vichy, Royat, Bourbole, Pourges, St. Nectaire and even Canterets,

have a favorable action on diabetes; this is due, Martineau thinks, to the fact that they all contain lithia, and some of them, notably Vichy and Bourbole, contain arsenic.

Any physician in country practice, where easy access can be had to a soda water generator can prepare for his diabetic patient Martineau's remedy. He has only to fill an ordinary quart bottle in which he shall have previously put a three-grain carbonate of lithia powder and a tablespoonful of the above-mentioned solution, with gaseous water from the soda fountain, and order the whole quantity to be taken during the day after meals.

As for the curative value of this prescription, there is justification for considerable scepticism. Dujardin-Beaumetz, at the meeting of the Société de Thérapeutique where Martineau's paper was read, expressed grave doubt as to whether the 67 cases, cited by Martineau, were typical cases of diabetes, and was tempted to believe that Martineau had fallen upon a series of cases of *alimentary diabetes*, like those treated by Cantani, at Naples, where abuse of pastry, sweets and starches had given rise to a temporary glycosuria that was not true diabetes.

Syphilitis Hæmorrhagica Neonatorum.

Franz Mraček has studied the hæmorrhagic phenomena in 132 syphilitic children born dead, or dying within forty hours after birth. Of the latter there were eighteen. The most noticeable changes were found in the medium-sized and smaller veins, which showed thickened walls and diminished or closed lumen; hence, infiltration of the neighboring tissues and venous

and capillary engorgement. The intermediate branches of the arteries showed a thickening of the *adventitia*, sometimes also of the *media*, with occasional occlusion of the lumen. Similar effects were found in the *vasa vasorum*, and in some instances there was beginning endarteritis of the carotids, crurals and iliacs, and thrombi of venous branches. The hæmorrhages were always previous to birth and caused by the increased blood pressure of delivery and the beginning of the individual circulation. In some cases of protracted and difficult delivery there were more than seven hæmorrhages.

R. Fischel has gone more deeply into the anatomical changes of the vascular walls in the hæmorrhages of hereditary syphilis. He examined the same in ten cases of children suffering from this cause, seven of whom were afflicted with the so-called *syphilis hæmorrhagica*. In every case there was thickening of the *muscularis* and *adventitia* of the arteries. The endothelium layer was preserved, and likewise the folding of the *intima*. These peculiarities of the vessels were in further comparative researches proved to exist in the non-syphilitic new-born, and the conclusion is reached that it is not, therefore, the cause of the hemophilia.—*Centralblatt f. d. med. Wissensch.*, May 21, 1887.

The Hypodermic Injection of Carbolic Oxide of Mercury in Syphilis.

Dr. Carl Schadek, of Kiew, adopting Professor Gamberini's recommendation, reports the results of the use of the above drug in the manner indicated, in ten cases. He practices the deep intra-muscular injection instead of the subcutaneous, burying the needle deeply under the aponeurosis of the glutei muscles, thus obviating the abscesses or indurations of its superficial use. This is the formula used for a 20 per cent. emulsion:

B Hydargyri carbolici oxydati.....gr. lxxv
Mucilag. gum arabici.....gr. lx
Aque destil..... $\frac{3}{4}$ v

The author injects a Lewin syringe full of this solution in one gluteus, or half this amount in each, repeating the dose not oftener than every second day. The pain is but little noticed by the patient and the whole operation is quickly over. The absence of abscesses, or other local troubles, the tendency to salivation subsequently noticed, and the appearance of mercury in the urine prove the ready absorption of the drug by the circulation.

The results in all cases were in a high degree satisfactory. Syphilitic symptoms of every kind were reduced in intensity, and in one case even gummatous abscesses were

healed by twelve injections, lighter cases by ten. In acute cases, 16 to 18 injections were required to cause the disappearance of all symptoms upon the skin or mucous membrane.

In 12 other cases of syphilis in women the symptoms of secondary syphilis disappeared with about ten injections.

The conclusion is reached that the preparation of mercury above mentioned has advantages over others because of its speedier absorption, less tendency to set up local troubles, and its more pronounced effect in quickly reducing all syphilitic symptoms.—*Allgem. med. Cent. Zeit.*, May 11, 1887.

Physiological and Therapeutic Action of Sparteine.

The results of Gluzinski's researches as to the action of sparteine upon cold and warm-blooded animals are as follows: 1. It exercises an intensive influence upon the circulatory system, and in a greater degree upon cold-blooded animals than upon the mammalia. 2. This effect is produced chiefly in the slowing of the cardiac activity, and to a less extent in raising the arterial blood-pressure. 3. By successive increase of the dose, three stages may be differentiated in the effects produced, whose explanation is found to consist in the relation of the vagus and muscular nerves. 4. Sparteine seems to have almost no effect upon the peripheral motor nerves. 5. Its action upon the spinal cord is shown by a preliminary heightening followed by a lowering of the reflexes. 6. Death is from asphyxia, caused both by its action upon the cord and the muscles of respiration.

Therapeutically the following points became manifest: 1. Sparteine exercises a positive influence in uncompensated cardiac disease. 2. This is soon shown (one hour) after exhibition in the improved quality of the pulse, and especially in the subjective feelings of the patient. 3. The promptness of its action is the most important distinction of the drug, since, as regard intensity, digitalis takes precedence. 4. Irregularity of rhythm was not corrected in the cases observed.

The dose is one and one-half grains of the powder.

The following are the indications for its use: 1. In view of its quick action its use is particularly recommendable when there is several subjective symptoms in consequence of insufficiency of cardiac muscle and when the slow action of digitalis necessitates too much delay. 2. When digitalis is from any cause contraindicated. 3. In angina pectoris, on

account of the promptness of its action, though the author has no experience with it in these cases. *Allgem. Med. Cent. Zeit.*, May 21, 1887.

Aneurism Cured by Position.

Dr. T. G. Richardson, of New Orleans, at the last meeting of the American Surgical Association, reported the case of a shoemaker, fifty-five years of age, who was admitted into the hospital for a painful swelling of the left thigh. The tumor, an aneurism of the femoral artery, was about the size of a goose-egg, irregularly flattened. None of the characteristic signs of aneurism were wanting. It was supposed to possess thin walls. The man looked anæmic and delicate. He had had syphilis about nine years before. The cause of the disease was supposed to be the irritation caused by hammering leather on an iron placed on his thigh. The tumor appeared to be inflamed by the manipulation. To overcome this, Dr. Richardson suspended the limb flexed at right angles at the hip and knee. He found on the first day an improvement in the condition of the tumor, and a few days later, that coagulation had occurred. A week later he was discharged, cured, and a few months after only a small nodule could be felt at the site of the tumor.

As this is probably the first case of femoral aneurism cured by this method, he desired to call attention to the fact that no pressure was exerted on the tumor, but that the only treatment was flexion, and suspension of the limb, especially the latter. He thought that gravity had a great deal to do with effecting the cure.

Salivary Calculus.

Polak reports the case of a tumor developing in the jaw of an otherwise sound man, 31 years old, subsequent to the extraction of a carious tooth. It extended from the border of the lower jaw to the thyroid cartilage and has a fistulous opening at the anterior border of the sternocleido-mastoid through which pus escaped. Various applications had no effect. An injection of iodine solution escaped into the mouth through the caruncula sublingualis. Since it appeared to be a tumor of the sublingual gland, a part was excised, and eleven days later a further excision was made, but there was no improvement. In sounding the opening twelve days after this, a rough, hard body was felt in the bottom that seemed to be the necrosed jaw bone. Upon the next day, when a resection of the jaw was attempted, a salivary calculus weighing 23 grains was found. It had been raised during

the night from the bottom of the abscess to the surface. The healing of the parts at once proceeded without interruption.—*Centralbl. f. d. med. Wissensch.*, May 21, 1887.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT LITERATURE.

—In the reprint of a paper read before the Baltimore Gynæcological and Obstetrical Society, May 10, 1887, Dr. Thomas A. Ashby, of Baltimore, discusses the treatment of amenorrhœa with permanganate of potash, and presents the records of these cases in point. He thinks it probable that the drug acts both as a general tonic and as a direct emmenagogue, although not as an ecboic.

—In a very able reprint Dr. T. Griswold Comstock, of St. Louis, Mo., strongly advocates the stimulant treatment of scarlet fever. In his remarks on the necessity for fresh air, etc., the following bit of sound sense occurs: "*There is much more danger from 'catching cold' during convalescence than when the fever is at its height.*"

BOOK NOTICES.

Dose and Price Tables of all the Drugs and Preparations of the U. S. Pharmacopœia of 1880, etc. By C. L. LOCHMAN, Translator of the first and second edition of the German Pharmacopœia, etc. Second Edition, 9 x 4½ in.; pp. xvi, 201. Philadelphia: Dunlap & Clarke, 1887. In paper covers, \$1.25; in flexible muslin, \$1.50.

This book is intended chiefly for the use of druggists, but is also of value to physicians who dispense their own medicines, and forms a convenient book of reference as to the nature and properties of all the drugs and preparations in the U. S. Pharmacopœia of 1880. The dose of each drug is stated. We would suggest that it would add much to the value of the book if with each poisonous preparation the antidote were mentioned.

Earth as a Topical Application in Surgery, etc. By ADDINELL HEWSON, M. D. Second Edition, 8vo, pp. xx, 309. Philadelphia: The Medical Register Company, 1887.

This book contains a full presentation of the well-known views of Dr. Hewson in regard to the use of earth as a surgical dressing. These views are generally thought to be somewhat extreme, and in our opinion they scarcely demand the extensive and discursive treatment which they receive in the volume before us.

THE
Medical and Surgical Reporter.
 A WEEKLY JOURNAL,
 ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D., } EDITORS.
 CHARLES W. DULLES, M. D., }

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
 N. E. Cor. 13th and Walnut Streets,
 P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The edition for this week is 6,000 copies.

TREATMENT OF TUMORS OF THE BLADDER.

The attention being devoted to the surgical treatment of tumors of the bladder, as evidenced by the programmes of the Association of Genito-Urinary Surgeons and of the American Surgical Association for this year, warrants a brief statement of the present opinion in regard to this subject.

The diagnosis of a tumor of the bladder having been made by means of the rational signs, and by examination of the urine, and of the bladder, through the rectum and the abdominal wall, an operation is justifiable in all cases except those in which the general condition of the patient is such that no surgical operation ought to be undertaken, or in which it is evident that the new growth is so extensive as to make its removal impracticable. Even in the latter case, so much relief is sometimes afforded by an exploratory operation, that it is justifiable whenever there is any reason to hope that it may do good.

The method of operating is a matter of importance. Sir Henry Thompson still contends for the utility of making the incision through the perineum, while the opinion of other surgeons, principally French and German, is in favor of the suprapubic method. There can be no doubt that the latter meth-

od secures a better route to the bladder; both for the purpose of inspection and for the purpose of removal of whatever may be found. It is also a comparatively easy method, when the operation is performed with deliberation and with due care to keep well down toward the symphysis pubis and to look out for the peritoneum. There is almost no danger of cutting the peritoneum, if care be exercised in making the incisions, and if the wound be kept clean, so that the operator can see what he is doing.

On the other hand, an incision through the perineum affords an excellent channel for drainage after the operation, and sometimes seems to effect relief of distressing symptoms, even when investigation shows that the new growth cannot be removed.

For this reason certain students of this subject have advised that, in all cases in which an operation is called for, an exploratory incision should be made through the perineum and the bladder carefully examined. If now it be found that the new growth can be removed through the perineal incision, this should be done. If removal in this way be impossible, an incision should be made through the hypogastrium and the removal completed, or carried as far as it can be. In such a case the perineal wound serves for drainage, and also tends to diminish the spasmodic contractions to which the new growth may have given rise. The suprapubic wound may be closed with sutures.

This plan of combining perineal with suprapubic cystotomy is rational and deserving of extensive trial; and we recommend it to the consideration of our readers, with the hope that they will give us the result of their experiences.

THE EFFECTS OF ETHER ON LIVING NERVES.

Messrs. Vaillard and Pitres are studying neuritis caused by injections of ether in the neighborhood of the nervous trunks of the limbs. These injections have often been followed by stubborn paralysis, and even by trophic disturbance. Experiments made upon Guinea pigs show that the anaesthesia and paralysis, which immediately follow the injection, spread rapidly and persist for many weeks or months without either diminution or augmentation. The injection, therefore, determines phenomena identical with those produced by severing the sciatic nerve, of which we can convince ourselves by a microscopic examination. This shows that the nerve is normal *above* the point where the injection has taken effect. At its point (immediate neighborhood) the lesions vary accord-

ing to the amount of the substance injected. Some hours after the injection the myelin mingles with the axis cylinder, which is then hardly distinguishable, as are also the nuclei of the inter annular segments. After the fifteenth day the myelin becomes pulvulent and the nerve sheath is regenerated by special evolution. Below the injection the nerve branches undergo Wallerian degeneration after the sixth day, as in nerve section. To sum up, ether determines necrosis of the fibres which it reaches, and acts upon them as a chemical poison. Perhaps by the side of these grave disadvantages we may acknowledge for these injections a favorable action in infrequent cases, as when the elongation of the nerves seems indicated.

This study shows several things of practical importance—first, that the frequently recommended perineural injections of ether may give rise to more grave results than has been supposed; and, second, that in some of the relatively rare cases in which nerve-stretching is indicated, the same result may be attained by the injection of ether.

MORPHINISM.

According to Lewinstein, the abuse of morphine leads to a state of chronic poisoning resembling alcoholism. He relates several cases of morphinism observed in his private and hospital practice, and gives, among others, the history of a man and his wife. The husband, aged thirty years, was a victim to the morphine habit, and for five years had taken 15 grains of acetate of morphia a day; he was suffering from insomnia, nervousness, exaggerated reflex excitability, hyperæsthesia, neuralgic pains, muscular contractures, and dryness of the tongue; perspiration was excessively profuse. There was at the same time incapacity for any kind of work.

The wife had reached, little by little, the daily dose of 12 grains of morphine, and was also a confirmed morphinomaniac. Menstruation had been arrested for four years; she was leaden-hued; had hyperæsthesia, trembling, and utter loss of appetite. In both cases memory and judgment remained intact.

Lewinstein suddenly suppressed the use of morphine in the case of the man, and gradually in the case of the woman. After alternations of amelioration and relapse, the patients got the better of their vice and recovered. Unfortunately, things do not always turn out so well; about three-fourths of the patients relapse into their bad habit.

Petit has shown that morphinism impairs all the functions, and entails a decadence of

the organism. Morphine takers are liable to abscesses of an intractable character; those who introduce the alkaloid by subcutaneous injection are prone to suffer such abscesses at the site of the needle punctures. Appetite and digestion fail, the bowels become obstinately torpid, menstruation ceases early in females, innervation languishes, and a peculiar state of mental decrepitude characterized by enfeeblement of the moral sentiments, the intellect, and the will, results; to this aggregate of mental symptoms has been given the name of *morphino-mania*, while *morphinism* is the generic name which includes all the physical results of chronic poisoning by morphine.

WAS IT SLANDER?

News comes from Norristown, Pa., that a physician who applied for election to the Montgomery County Medical Society and was rejected, has instituted suit for slander against one of the members of the Society who charged him with unprofessional conduct. From the telegraphed report of the matter, we presume that the charge was made at a private meeting of the Society. The Board of Censors at the proper time reported adversely on his application for election to membership, and the candidate was rejected.

This suit opens a question of the utmost importance to all medical men, and we hope and believe it will be settled in such a way as to establish the fact that statements made in good faith to a Board of Censors, or to a County Society, as to the fitness of candidates for membership are of the nature of privileged communications, and do not subject the maker of them to any suit at law. Of course, this could not excuse charges of a truly slanderous nature, made wilfully and with malice. But it would be a very unfortunate thing if the members of a Society could not freely disclose, to their fellow members or to the Censors, appointed to investigate the fitness of candidates for membership, what they may know or honestly believe as to the professional standing of a candidate.

We shall look with interest for the issue of this particular case, and report it promptly to our readers.

—The *Medical Review* says that a Chinese doctor has arrived in St. Louis, and offers to break his own arm if another surgeon will do the same, and then prove the superiority of his treatment over that of the other.

NOTES AND COMMENTS.

THE MODERN TREATMENT OF COMMON DISEASES.

Chlorosis.

Calcaria chlbrhydrophosphorica is recommended by Mercadier in chlorosis, as being superior to the simple phosphate of lime. Ewald praises the citrate of iron and quinine in anæmia, chlorosis, etc., but he thinks more highly of chinoidin, and follows Hague's formula:—

- R Chinoidini puri.....3 ijss
 Acid. tartar.....
 Ferr. sesquichlor.....āā 3 j
 Glycerini.....gtt. xx
 Rad. althææ.....Θ iv
 Rad. gent., q. s. ut ft. pil. No. 200.
 S.—Three or four pills four times daily.

Mauthner gives the extractum sanguinis, thought by others to be of doubtful efficacy. Gillespie speaks enthusiastically of ferrum bromatum. Of arsenic it is unnecessary to speak, being universally recommended; though it may not nowadays be altogether absurd to recall the Prussian ministerial ordinance that made it illegal to give more than $\frac{1}{120}$ of Fowler's solution at one time! Hannon recommends sulphate of manganese for chlorosis, and in combination with iron the manganum chloratum. Leras thinks natrium pyrophosphoricum ferratum the best and most digestible of the iron preparations. It may be given according to either of the following formulæ:—

- R Sodii pyrophosphorici ferrat.
 Sem. cacas ab ol. liberat.
 Sacchari albi. āā xxxvij
 Mucil. aq. gummi arab., q. s.
 to make pil. No. 50.
 S.—3 pills half an hour before each meal.
 R Sodii pyrophosphorici ferrati. gr. xxij
 Aquæ destill. 3 xij, 3 vij
 Syr. simpl. 3 ij, Θ v
 M. S.—A wineglassful morning and evening.

Vinum ferratum is also praised, a wineglassful twice daily; likewise succus centaure, and succus trifol. fibr. Oesterlein gives the following as an emmenagogue in chlorosis:—

- R Myrrh.....
 Aloes.....
 Ferri. pulv.....āā 3 j
 Extr. valerian., q. s. ut ft. pil. No. 100.
 S.—5 pills three times daily.

Teissier gives the following for chlorosis:

- R Ferri pulv.....
 Cort. cinnamon.....āā gr. iss-ijj
 Sacch. alb.....gr. ix
 S.—One powder of above before each meal.

Oesterleins' formula is:—

- R Ferri pulv.....3 j
 Pulv. cort. cinnamon cass.....3 ss
 Ext. card. bened. q. s.
 Ft. pil. No. 60.
 S.—3-4 three times daily.

Blaud's pill as modified by Niemeyer, is as follows:—

- R Ferri sulph.....
 Potass. carb. pur.....āā 3 iij-3/4
 Tragacanth q. s. ut ft. pil. No. 100.
 S.—Three pills three times daily; later, 4-5 pills.

Lebert gives:—

- R Ferri sulph.....
 Sodii bicarb.....
 Extr. gent.....āā 3 j
 M. Ft. pil. No. 60.
 S.—3-4 pills daily.

Kämpf's "red-cheek pill" is the following:—

- R Ferri sulph.....3 j
 Extr. myrrh.....
 Galbani.....āā 3 iij
 Extr. aurant. cort. q. s.
 Ft. pil. 120.
 S.—6 pills or more every three hours.

For chlorosis with constipation, H. E. Richter gives:—

- R Ferr. lact.....3 ss
 Ext. aloes.....
 Rad. rhei pulv.....āā 3 ij
 M. Ft. pil. No. 100.
 S.—3 pills morning and evening.

A pleasant manner of giving the much praised lactate of iron is:—

- R Ferr. lact.....
 Elæosacch* calami.....
 Sacch. alb.....āā Θ ij
 M. Divide into ten powders. S.—One powder morning and evening.

Osler gives the preference to the Blaud-Niemeyer pill previously quoted, and Bartholow gets the best results from the combination of iron and arsenic. Hammond, believing in the nervous origin of chlorosis holds that arsenic is the true remedy. Weir Mitchell advocates rest, forced feeding, massage and faradization.

The pilulæ ferri iodidi of the British pharmacopeia are composed of:—

- R Ferri pulv.....3 ss
 Iodi.....3 j
 Sacch. pulv.....gr. j
 Rad. liquir. pulv.....Θ vss
 Aquæ destil.....gr. xxxvij
 M. Ft. pil. No. 100.
 S.—1-2 pills several times daily.

* A favorite vehicle among the Germans. It is an intimate mixture of ethereal oil and sugar, gtt. i to 3 ss. Used when it is desired to add a liquid to the oil; to neutralize an unpleasant taste; as an adjuvant to powders; or as a vehicle of the ethereal oil itself.

Vaccination.

In an admirable article on vaccination, in the *Archives of Pediatrics*, June, 1887, Dr. William T. Plant, of Syracuse, N. Y., says: The material for vaccinating is now taken from both the heifer and the child; hence we speak of bovine and human virus. Until recently the latter was in almost exclusive use. From 1800, when the practice was introduced into this country, until 1870 bovine lymph was seldom procurable, because epidemics of cowpox were of infrequent occurrence. But about the latter date its production on a large scale by vaccinating calves and heifers began to be followed as a business. Establishments for the propagation of kinexox are now quite numerous, and within a few years the use of human lymph has greatly lessened.

But there are some drawbacks to this new fashion. Bovine lymph, as now supplied, is less reliable than the other. Failures with it are so frequent, that probably many communities are less secure against smallpox than they believe themselves to be. Possibly one reason may be that the virus supplied is not quite fresh. But a principal cause, I am sure, is in a certain lack of affinity between lymph from the cow and the human system.

Bovine lymph is also less regular in its operation. Though usually mild enough, it occasionally works with unexpected and undesired energy, causing much suffering and leaving unsightly scars.

An asserted advantage of animal virus over human is immunity from the liability of conveying other diseases than vaccinia. This is a moving consideration with the laity, who believe that all sorts of eruptions and blood-disorders are chargeable to human lymph.

It is true that vaccination is sometimes followed by an erythematous, an erysipelatos, or an eczematous eruption. But, these, when not accidental, are caused by the local and constitutional irritation following the operation, and are oftenest seen after the use of bovine lymph, because it is more irritant than the other. I cannot find reliable warrant for the opinion that chronic enlargement of glands, or scrofula, or consumption, or any of the ordinary skin-eruptions have ever been transmitted from child to child through vaccination. But there is no doubt that syphilis may be conveyed with vaccinia. It has been thought that in such instances there was an admixture of blood with the lymph, and that care to exclude this would obviate danger. Such was until lately my

own view. But one of the experiments of Dr. Cory, chief vaccinator attached to the National Vaccine Establishment in England, makes me waver. This gentleman repeatedly vaccinated himself from children who were actively syphilitic, using, with greatest care, only the clear lymph. On July 6, 1881, he vaccinated himself in three places with clear lymph from a three months' old child who had an eruption and sores that were evidently syphilitic. In three weeks syphilitic papules appeared at the seat of two of the punctures. These were followed by sore throat, roseola and other indubitable evidences of constitutional syphilis.¹ From this it would seem that clear limpid lymph *may* be a medium of carrying that disease from one person to another. But, conceding this, it is to be remarked that this child was selected for this experiment because it had syphilis in an aggravated form, and that no medical man would ever think of taking lymph from such a source. There is no reason in all this for the rejection of all human lymph, but rather for careful scrutiny of the antecedents and present state of every child before allowing others to be vaccinated from it.

DEGENERATION OF LYMPH.

It has been claimed that lymph gradually parts with its protective virtue by passing successively through the human system, and that if we would give the completest possible insurance against smallpox we must use the bovine product altogether, or return to the cow at short intervals. We pause another moment to examine this claim. In 1816, Jenner wrote that the vesicles he was then producing were in every respect as perfect as in the first year of vaccination, though, to the best of his knowledge, the matter from which they were derived was taken from the cow about sixteen years before. In accord with that have been the observations of many eminent physicians since. Professor Hebra asserts that in the principal vaccine establishment at Vienna lymph has been carried down without interruption from the first vaccination at the beginning of the century, and that it now "takes" as well and is as protective as at first.² Dr. Charles V. Chapin, writing from the office of the Superintendent of Health, Providence, Rhode Island, December, 1885, says they were at that time using stock that had been maintained by continuous transmission from child to child since 1856 without being once renewed from the cow; that nearly forty-seven thousand persons had

¹ Boston Med. and Surg. Journal, vol. iii, page 188.

² Manual of Skin-Diseases.

been vaccinated from it; and that it had shown itself not inferior to the bovine product in protective power, besides being more certain to take and less liable to produce troublesome sores. My belief is that lymph may degenerate, not by the mere fact of transmission through the human body, however many times the transmission may be made, but through lack of care to choose stock from healthy and vigorous subjects. Let a farmer gather seed-corn from stunted ears growing on poor soil, and he will soon be raising degenerated crops. This expresses a general fact of vegetable and animal propagation to which vaccination is no exception.

FORMS OF LYMPH.

The lymph used in vaccinating, whether human or bovine, is either fluid or dry. As a fluid it is conveyed by the lancet directly from the vesicle to another person, as in "arm to arm" vaccination. When numbers are to be operated on at once, as in schools and factories, this is the surest and best way. Fluid lymph may also be taken up from the vesicles in capillary glass tubes, which, after closure of the ends, are put aside for future need.

The use of dried lymph is, in this country at least, much more common. At the proper time the vesicle is punctured and the exuding lymph collected on ivory or quill-points, and permitted to dry, or the vesicle may be left to mature. Its lymph then dries down into a dark brown crust, that falls from the arm about three weeks after vaccination. The bovine crust is notoriously unreliable, and is not very much used.

Victor Horsley on Temperance.

Professor Victor Horsley, F. R. S., F. R. C. S., speaking on the subject of temperance at the annual meeting of the Church of England Temperance Society, said that although he was unable to pose as an Nestor, and review the history of the temperance question from the medical point of view, yet he asked to be allowed for a moment to assume that part, and give a kind of *apologia* for the past position of the medical profession. Medical science, unfortunately, from the very nature of her general knowledge, was necessarily still in the chains of empiricism. It was thus bound, in common humanity, to receive the statements of any one, based upon fair evidence, and to try and test the results which such an one might claim to have obtained from his own experience. It was in this way that the medical profession became

enamored of alcohol as a drug, more especially in the treatment of acute disease and fevers. The example and experience of the late Dr. Todd appeared to have great weight. Unfortunately, to his writings was due the universal employment of alcohol by the medical profession. Things had greatly changed. Physiological science had advanced immensely. They were now gradually freeing themselves from the slavery to which they were before subject, and that they knew that the position of alcohol, from the medical point of view, had to be considered in the two opposite conditions of a food and of a drug. Researches of men like Parkes, who headed the movement, had given the medical profession the true scientific value of alcohol, and the value they knew to be very nearly zero. He should substantiate from clinical experiences what he was about to say. With regard to alcohol as food, he reminded his hearers of a certain symposium that was written in the *Contemporary Review* in 1879; in the most brilliant of papers contributed by the medical profession, that by Sir James Paget, their most revered teacher in surgery reference was made to the popular belief that, as the drinking of alcohol existed as a general custom, it was a good thing. Dr. Parkes, twenty-five years ago, pointed out that, because one thing was a custom, it was no evidence of the truth. Cannibalism was a custom in some parts of the world, and was it therefore good? There was one scientific point ascertained beyond all doubt with regard to alcohol in its first influence upon the human system and animal body, and that was that, in proportion to the dose, it checked the tissue-changes of the body. Alcohol did, in greater or lesser degree, check the activity of these processes. This could be produced with even a small dose; carried to a greater extreme, its effect was not that of a regulator, but it proved an extra blocker of the machinery. "It seems," said the speaker, "a kind of chronic suicide that they were always to put the brake on—to put the brake on the development of their natural energies. What they wished to do without infringing the laws of nature was to get the greatest amount of energy out of their bodies. Why hinder it?" Professor Horsley alluded to the series of experiments on the influence of alcohol upon plant life carried out by Dr. Ridge, of Enfield, who found that one-sixteenth per cent. of a solution of alcohol checked the growth of water-cress, and that a tenth solution of alcohol killed its seeds. The position of the medical profession with regard to alcohol as a food was becoming

more and more defined. Professor Horsley next drew attention to the researches of Dr. Hare as to the use of alcohol as a medicine, and to the fact noticed by him—the large decrease in the use of alcohol at the London hospitals, and the largely increased use of milk and other forms of nutrition. They had a large amount of evidence to show that the medical profession estimated at its full value alcohol as a drug. Referring to the London Temperance Hospital, where, since, 1873, the experiment as to whether alcohol was useful had been tried to the uttermost, the evidence was perfectly wonderful to those who, like himself, used alcohol occasionally as a drug. It is true that they required even yet more statistics and more figures in the profession, and must wait before receiving the statistics as those upon which they would absolutely rely in the treatment of patients; but the result so far gained was so wonderful and so overwhelmingly contradictory to many preconceived notions, that he had no doubt as to what the verdict would be in the half jubilee of the Temperance Hospital. In this hospital, which had admitted 4,153 persons as in-patients, and 23,000 as out-patients, alcohol had only been administered as a drug in four cases. Dr. Edmunds, the senior physician, writing in 1884, stated that among fifty-three typhoid fever cases there had been five deaths, and at the examination it was found that no administration of alcohol could have possibly saved them. The cases of recovery had done remarkably well, and on the whole there was a mortality of rather less than 1 in 10. This mortality was smaller than the mortality in any other hospital in London at that period, and there had not been given to one of these a particle of alcohol either as diet or medicine, and yet a large number ought to have died according to the old view of the treatment of the disease. Figures spoke for themselves, but it seemed to him the use of alcohol as a food and its excessive abuse were dependent upon what must be regarded as possible from the view of causes which led to its abuse. The abuse of alcohol was produced from three groups of causes: from mental and moral failure of strength; secondly, from the general prevalence of unsanitary conditions; and, lastly, from the unjust and wicked facilities for getting the poison.—*British Medical Journal*.

News comes from Chicago by way of the daily papers, of a recent operation in which both the sciatic nerve and the crural nerve were stretched at the same time, in the case of a man who was suffering from tetanus.

CORRESPONDENCE.

Homœopathy.

ED. MED. AND SURG. REPORTER :

In your issue of June 4, you ask to have your readers reply to the statement, "Homœopathy has increased and is increasing in the United States," by answering three interrogatories.

It would require too long an article to answer intelligently, therefore, a more or less general statement will have to suffice. That I ought to be able to reply, permit me to state, that I began practice at the dawn of a genuine homœopathic practice in this country, and before the rural districts had one of its fellows. All who lived in that day well recollect that *six weeks* only were required to fit a person to set out as an antagonist of death in that kind of practice. No anatomical nor physiological knowledge was deemed necessary to "treat symptoms." With Hahnemann's Organon under the arm, the man was fully equipped. Turning to the symptoms of which the patient complained, he there found the remedy. The cause, or organ involved, mattered not. Judges, boys from the farms, and clerks from the stores were among those to be seen with the inevitable Organon. But I must not dilate, but come to question 1 :

I believe the number of persons practicing *under the name*, (italics mine) of "homœopathy" is increasing. To question 2 : I reply, the number of persons under the treatment of *what are called* homœopathic practitioners is increasing, for the very good reason that the *hybrid practioners of homœopathy* are increasing. In answer to question 3 : "How the state of affairs is to be explained," let me say that the explanation is very simple, viz.: that purely homœopathic practitioners (and I know of only one) have been rapidly disappearing for fifteen years.

When homœopathy began to wane from its position of inefficiency, the young men began to attend what are scurrilously called Allopathic colleges, as at that time there were none that taught the homœopathic dogma. They obtained, in many instances by falsifying about their future intentions, a medical education, and then at once set out with their infinitesimal doses. When the little pellets would not do, the regular practice (so far as they knew it) was pursued.

At once the people began to say, "We don't believe much in homœopathy, and my doctor practices both ways." Even intelligent people believe you can serve two mas-

ters, so far as the treatment of disease is concerned, if you cannot in spiritual matters. As proof of this, not long since I was asked to see a gentleman who was under the care of one who boasted of his success in the practice of homœopathy. Knowing full well a consultation was impossible, yet thinking that I might visit the case, the doctor left a line with the patient, stating that he had "given digitalis, aconite, with occasional doses of quinine," in an *unsealed envelope*: yet that patient's faith in *homœopathy* was unshaken. "Oh! Shame where is thy blush."

Yet I find I am doing just what I intended not to do. Evidently there is no "soul of wit" in this communication, if it consists in brevity.

D. COLVIN.

Clyde, N. Y., June 25, 1887.

Base Ball for Physicians.

EDS. MED. AND SURG. REPORTER:

Sirs:—While in conversation with some medical friends a few days ago, some expressed themselves as not yet having lost their interest in our National game of base ball, and wished there was a way in which physicians could take active part in the exercise of the game without detracting from professional dignity. I would propose to all who would avail themselves of the rejuvenating influences of the game to send their names with preferred fielding positions to my address. If a sufficient number are heard from, we could in this city emulate the example of the physicians of Brooklyn who were represented by the "Galen" base ball club of that city. The Galens played any club composed of other physicians, lawyers, ministers or business men, and with invariable success.

Very sincerely yours,

A. H. P. LEUF.

Treatment of Tedious Labor.

EDS. MED. AND SURG. REPORTER:

It has always been my custom to study the character, condition, and, so to speak, the individuality of each case of labor to which I am called to attend. Physicians are in the habit of making an examination by the vagina in order to ascertain the progress of labor, without paying any attention to the individual state of either the physical or nervous condition of the patient, and wait the labor's own time for a termination.

This I never do; but examine carefully the patient's physical condition. If I find

her feverish, and with a dry skin, and quick pulse, and rigid mouth of the womb, I usually prescribe a solution of tartar emetic, in one-eighth of a grain doses every hour, until the feverish state is relieved; and when I have relieved these symptoms I generally have the gratification of seeing the case progress to a speedy and healthy termination. If I find no feverish condition, but observe the patient to be nervous, anxious and troubled, with frequent and annoying pains, attended by a tedious progress of the case, I give the patient every three or four hours a pill, composed of one-fourth of a grain of sulphate of morphia and three grains of sulphate of quinine. After patients, in this nervous, anxious condition, have taken two or three of these pills, they become calmer and stronger; and no physician, but he who will try this plan, can know how rapidly and encouragingly labor will assist and relieve itself of its painful and perilous offices under this treatment. In this way I frequently shorten the duration of tedious labor five or six hours, and thereby often obviate the use of forceps.

J. B. JOHNSON, M. D.

Washington City, D. C., June 14, 1887.

Scarlet Fever.

EDS. MED. AND SURG. REPORTER:

I take this opportunity to ask you, or any of your numerous readers among the profession, regarding their experience in the treatment of scarlet fever, as to the indications for giving stimulants, particularly whiskey, which I have found preferable over all others. In the experience of the writer, the mild form of scarlet fever needs very little medicinal treatment, but in the form of malignant scarlet fever stimulents are necessary from the first onset of the attack. I take the liberty to send you enclosed reprint, in which I have advocated the cautious application of refrigeration, (the wet sheet), and, also whiskey, as giving better therapeutical results than any other plan of treatment. My experience has been most favorable in the use of these remedies in the most serious cases of this most formidable disease, and I particularly request the opinions of those of who are experienced in this most important matter. In nearly every recent medical journal, we have accounts of antipyretics mentioned, such as Antipyrin, and later, Antifebrin, but we hear very little said of that antipyretic described by an English physician, more than 160 years ago. I refer to Dr. Hancock, rector of St. Margaret's Lothbury, England,

who published a pamphlet entitled, "*Febri-fugum magnum*, or common water the best cure for all fevers." As regards the "antipyretic" effect of cold water especially in scarlet fever, I think we can elicit an almost unanimous opinion as to its efficacy in the disease in question, but regarding alcohol as therapeutically possessing the properties, whereby it may be given to produce the fall of temperature in fevers, there may be a diversity of opinion among our colleagues.

As one of the old subscribers of your most excellent REPORTER. I desire to hear the voice of the profession regarding the matter.

T. GRISWOLD COMSTOCK, M. D.
June 7th, 1887.

The Grocers' Prize.

In response to several inquiries we give below a reproduction of the official announcement of the famous prize. It would be a source of rejoicing to the thousands who read the REPORTER if one of their number should be successful in solving the problem, and still more gratifying to the Editors of the REPORTER if this notice should be the cause of such a success,—and there is no reason why it should not:

THE WORSHIPFUL COMPANY OF GROCERS,
LONDON.

ORIGINAL RESEARCH IN SANITARY SCIENCE.

QUADRENNIAL DISCOVERY PRIZE OF £1,000. 1887—1890.

In accordance with the terms of the Company's scheme, the Court announce that the problem proposed as the matter of competition for the first Discovery Prize (1883-1886) viz.:—

"To discover a method by which the Vaccine Contagium may be cultivated apart from the animal body, in some medium or media not otherwise zymotic:—the method to be such that the Contagium may by means of it be multiplied to an indefinite extent in successive generations, and that the product after any number of such generations shall (so far as can within the time be tested) prove itself of identical potency with standard Vaccine Lymph," has not been solved by any of the Candidates. The prize has, therefore, been withheld, and the same problem is, subject to the conditions of the Scheme, again proposed for investigation.

The Prize is open to universal competition, British and Foreign.

Competitors for the Prize must submit their respective Treatises on or before the 31st of December, 1890, and the award will be made as soon afterwards as the circumstances of the Competition shall permit, not later than the month of May, 1891.

In relation to the Discovery Prize, as in relation to other parts of the Company's Scheme in aid of Sanitary Science, the Court acts with the advice of scientific assessors.

All communications on the subject are to be addressed to the Clerk of the Grocers' Company, Grocers' Hall, London, E. C.

GROCERS' HALL, June, 1887.

Predicting the Sex of the Unborn.

EDS. MED. AND SURG. REPORTER:

SIRS: In your last issue a point is raised in relation to predicting sex of unborn child, and I hope there is a mistake in reporting the matter to you, or that you have erred in printing the article, otherwise my observations on the subject will flatly contradict those of the author. I never heard the subject mentioned by medical men, but had noticed for the last few years that, with one exception, every male child that I have delivered, or assisted at its delivery, has been most prominent upon *right* side of mother, while every female has been upon *left*. Now I can conceive of no scientific explanation of this circumstance, and do not know as any can be given; but, with the exception of the one failure mentioned above, I have predicted correctly every time. If no mistake has been made in Dr. S.'s report of cases, it will tend toward the conclusion that there can be no physiological explanation of the subject.

It is not as important in either case as it would be if it gave information regarding time of impregnation in its relationship to the catamenia. I have commenced to keep a record of all cases, where any reliable information can be procured, of the time of conception.

It would seem to me of vast importance to the parent could there be anything definite determined about this matter.

DR. H. L. MANCHESTER.

Pawlet, Vt., July 1st, 1887.

Longevity in the United States.

The St. Louis *Globe-Democrat* devotes several columns to facts about aged persons. These facts attest the wonderful vitality to which some Americans attain. A Gasconade county, Mo., woman, for example, ninety-eight years old, can walk two miles at a time. Another Missourian, at the age of ninety-one shoots game and wears no glasses. A physician of Chillicothe, in the same State, is eighty-nine and reads the finest print without artificial help. The City Treasurer of East St. Louis is ninety and has never known a sick day. Pierre, Wis., has an authenticated instance of a man reaching the age of one hundred and two. And so runs on the story of extreme age and yet of much activity and hopefulness developed in various parts of the country.

NEWS AND MISCELLANY.

Report of the Seybert Commission on Spiritualism.

The Seybert Commission, appointed by the University of Pennsylvania to investigate "all systems of morals, religion or philosophy which assume to represent the truth, particularly modern Spiritualism," recently made a preliminary report, which is about to be published for the University. A copy of the general report, with extracts from the detailed minutes of the secretary of the Commission and reports of *séances*, was made public on June 5.

Mr. Henry Seybert died in 1884, leaving a sum of money to found a chair of Philosophy in the University of Pennsylvania, upon condition that a commission be appointed to investigate Spiritualism. The Commission was originally constituted by the selection of Dr. William Pepper, Dr. Joseph Leidy, Dr. George A. Koenig, Professor Robert Ellis Thompson, Professor George S. Fullerton and Horace Howard Furness, LL.D. To these were afterwards added Mr. Coleman Sellers, Dr. James W. White, Dr. Calvin B. Knerr and Dr. S. Weir Mitchell.

Mr. Thomas R. Hazard, a personal friend of Mr. Seybert, and a Spiritualist, aided the Commission in obtaining *séances* for the investigation of what is known as independent slate-writing. *Séances* were held with a score of the most prominent "mediums" including Mr. Henry Slade, on conditions imposed by the mediums, and experiments were also made with slates prepared and sealed by the Commission. With the latter there was no success, except that in one case the piece of pencil was removed from between the slates and microscopic examination showed that it had been abstracted after prying the slates apart slightly, without disturbance of the seals. There was no writing on the slate, but there were powdered remains of the soap stone left on the wooden frame at the place where it had been extracted. The Commission detected one of the mediums unscrewing the slates beneath the table and writing on them, and another in substituting prepared slates for those supposed to be presented for the spirits to write upon.

In one case detection was secured by the aid of a hand mirror, which, being held under the table, reflected the hand of the "medium" at work on the slate. In another case a member of the Commission, by upsetting some slates within reach of the medium, disclosed that they had been prepared to be substituted for those in use.

The Commission says: "In dismissing this subject of independent slate writing we repeat, what we think Spiritualists will generally grant, that this phenomenon can be performed by legerdemain. The burden of proof that it is not so performed rests with the mediums. This proof the mediums will neither offer themselves, nor permit others to obtain. Investigators, therefore, are forced to bring to bear their own powers of close observation, sharpened and educated by experience. Be it remembered that what we have here stated applies solely to the process whereby the communication is written on the slate. With the substance of the communication, whether pertinent answers to questions or dreary platitudes, we are not now dealing. Whether these answers be ascribed to spirits or to what is termed clairvoyance, they would be none the less true or false if delivered orally by the medium; all that we are sure of is that the writing down of these communications, be their substance what it may, is performed in a manner so closely resembling fraud as to be indistinguishable from it. It would be a mere matter of opinion that all independent slate writing is fraudulent; what is not a matter of opinion is the conviction, which we have unanimously reached as a commission, of its non-spiritual character in every instance that has come before us."

The Commission adds that a professional juggler performed before them without detection much more wonderful feats of slate writing than any done by the mediums, and afterwards explained the details of the trick to one member of the Commission. The report gives some account of experiments with mediums who produced rappings, spirit hands, etc., explaining how the tricks are, or may be done, and ends as follows:

"In conclusion we beg to express our regret that thus far we have not been cheered in our investigations by the discovery of a single novel fact. But undeterred by this discouragement, we trust, with your permission, to continue them with what thoroughness our future opportunities may allow, and with minds as sincerely and honestly open, as heretofore, to conviction."

—Schwalbe believes malarial fever to be due to a poison and not to an organism. He claims that, by making animals absorb repeated doses of sulphide of carbon, or oxy-sulphide of carbon dissolved in poppy oil, he can induce the alterations in the blood and organs which are present in patients dead of malarial fever.

Milk of Swill-fed Cows.

In *Science*, June 10th, 1887, there is an interesting series of letters in regard to the wholesomeness or unwholesomeness of milk obtained from cows which have been fed on what is known as "distillery swill."

Some sanitarians believe that milk from animals so fed is not only of poor quality, but actually detrimental to health, and even poisonous to young children. Others regard such milk as inferior in quality, but not harmful. The matter is a vital one to the thousands of children in our large cities who depend upon milk as their sole sustenance, and *Science* has deemed it of sufficient public interest to endeavor to obtain facts which bear on the question, and opinions of those whose experience and observation enable them to express intelligent opinions on the subject. With this end in view, the following questions were sent out to the health-officers of all the principal cities, and to the most prominent sanitarians of the United States and Canada:

1. What opportunities have you had for observing the effect of feeding distillery swill to milch-cows?

2. Please state any facts within your knowledge which will help to determine its effect on the milk.

3. What references can you give to any recorded facts in published or unpublished reports bearing on this subject?

4. What analysis can you give of milk obtained from cows so fed?

5. What is your opinion as to the wholesomeness of distillery swill as food for cows?

6. Are there any laws or ordinances in your city and state which bear on the question? If so, please send copies thereof, or, if this is not convenient, a reference to them.

To this letter many answers have been received. Some of these are from those who state that they have never had any experience with the use of distillery swill or its effects on the milk, while others give the results of the feeding of brewery grains, evidently confounding them with distillery waste,—a subject of great interest, but which is not within the scope of the present inquiry. Still other responses are from those who have had opportunities of investigating the subject and have availed themselves of them, and whose testimony is therefore of great value. In addition to this, letters have been received from physicians and others, who, while having had no practical experience with the article of food in question, are still competent to speak on the subject from their general knowledge.

One of the most moderate, and probably

most valuable, letters so far published is from Prof. William H. Brewer, of Yale College.

Prof. Brewer says: I have a decided *opinion* that swill-milk is unwholesome; but this opinion is founded on general facts rather than on specific proof.

The following are among the facts inducing this belief:

1. That the health of cows affects the wholesomeness of their milk is proven beyond any doubt; and the health of cows fed largely or wholly on distillery swill is poor, as is abundantly shown by their general condition and by their high mortality.

2. It is well enough known that the food of cows affects their milk, and that their chief food largely determines its character. No one claims that distillery swill is the normal food of cows, or is wholesome food when fed in relatively large quantities.

3. Swill-milk undergoing spontaneous decomposition behaves differently from normal milk; it is usually acid when drawn, while normal milk is alkaline; it behaves differently in the processes for the manufacture of butter and cheese (and therefore probably also under the digestive processes),—so differently that creameries and cheese-factories refuse it. This is universal so far as I know anything about them.

4. Milk readily absorbs infections, and numerous epidemics of disease have been traced to this source. It also absorbs odors, and swill-milk stables are proverbially foul and stinking. These facts make me believe that swill-milk is unwholesome. I have never found any facts pointing in the opposite direction. Some are negative; others point in this direction.

The Purification of Water.

It has long been known that water may be clarified by the formation in it of a precipitate which, as it falls, will carry down mechanically the lighter, and of course the more dangerous portion of the suspended matters, which otherwise are very slow in separating. In Clark's well-known process for softening water a sufficient quantity of lime to combine with the free carbonic acid is mixed with the water. The precipitate of carbonate of lime—if we may still use the familiar old name for the calcium carbonate of modern chemists—carries down with it all suspended matters, including bacteria, and the water remains not only softer but very much purer. Carbonate of soda is an even more powerful precipitant, as it removes permanent as well as temporary hardness. In either case the deposition, is however, some-

what slow, and to avoid the use of depositing tanks a filter press was used in the Porter-Clark process, which was shown in action at the Health Exhibition. An American contemporary, the *Boston Medical and Surgical Journal*, reports that Prof. Dobroslavine, of St. Petersburg, advises as a good precipitating agent a solution of perchloride of iron followed by a solution of carbonate of soda. Simple and devoid of inherent novelty as the suggestion is, it is very sensible. Translated into English weights and measures, the quantities used are about three grains of perchloride of iron four grains of soda crystals per gallon of water. The precipitate is said to settle in about forty-five minutes and to leave the water perfectly clear. The quantity of carbonate of soda is not sufficient for the complete decomposition of the iron salt, but would convert it into a heavy, insoluble, basic chloride, but which would doubtless settle easily. So simple an experiment is well worth trying. It is noteworthy that by slightly increasing the quantity of carbonate of soda the water could be softened. We have often wondered that the softening of water for domestic uses is not more frequently practised in private houses. The addition of a very small quantity of carbonate of soda to the water in a cistern will remove even excessive hardness in a few hours at an almost inappreciable cost. If the cisterns are used in pairs the white deposit from one may from time to time be removed by flushing with water while the other is in use. The troublesome furring of boilers and hot-water apparatus might in this way be avoided. —*The Lancet*.

A Tribute to Physicians.

The physician of the period received this tribute from Gov. Ames (Mass.) recently, in an address before the Medical Society of Massachusetts: "It must be said that, as much as some of us, individually, dislike the doses which you prescribe, we cannot do without you. You are all powerful with us when we are most in need of the sympathy of our fellow men, and you use that power with such skill and discretion that the physician is often the best, and he is almost always the wisest friend of the family. Time was when the dominion of the sick room was divided between the doctor, the clergy and the lawyer; but now no one disputes with you for preëminence in that place, unless it be the nurse, that modern adjunct to your profession for which we cannot be too grateful to you. In whatever way one turns, one sees something which ought to evoke his

gratitude to you. In public improvements which tend to raise the standard of the general health none are more active; in securing better lighting, improved ventilation and thorough drainage for our homes and places of business none take a greater interest. Indeed, you have become, and to our advantage, preventers of, rather than curers of, disease, and that life is lengthened, with all its opportunities, all its blessings, is largely due to your efforts."

Insanity Fighting Insanity.

An interesting instance of fighting insanity by insanity, the *Scientific American* says, has recently been noticed among the Blackwell's Island patients. Two lunatics had been received who were disposed to commit suicide. In addition each possessed a special delusion, one to the effect that he was a cow, the other that his head was an iron ball, and was to be rolled along the floor. They carried these beliefs into action, one striking his head against the padded walls of his cell, the other rolling his head, and of course his body with it, along the floor. The two patients were placed together, and each was privately informed of the other's weakness, and warned to watch his companion to prevent him from taking his own life. Thus each had a charge in the other. Their vigilance was unceasing. Each supposed himself perfectly sane, and this belief was accompanied by considerable scorn for the other's weakness of intellect and accompanying delusions. Gradually under the influence of this treatment the patients were observed to improve. To have their attention centered on definite duty and on objects external to themselves proved a tonic for their diseased minds, and gradually a complete cure was effected, and they received their discharge from the asylum.

French Wines and Liquors.

United States Consul Gifford, at Bordeaux, warns the American public to beware of French liquors, more especially brandy, because *no pure French brandy* is sent hither. After commenting upon the methods employed in making brandy for export, he goes on to say that the labels on the bottles do not represent the quality of the liquor they contain. The dates 1863, 1870, 1875, etc., do not, he says, mean that the enclosed liquor is brandy put up in those years. It means that the liquor has been made to resemble as closely as possible that which was really made in those years. In other words, the brandy sent hither from France is spurious, a concoction put up in the laboratory, in

which the taste of good brandy is counterfeited by various chemicals.

It is worthy of comment that, while the laws against selling spurious wines and liquors in France are rigid in the extreme, little or no attempt is made to prevent the chemical preparation and adulteration of these liquids for exportation.—*Scientific American*.

Steatite as a Dentifrice.

Several years since, Mr. Paul Vigier, of Paris, discovered that the addition of powdered soap-stone to water in steam boilers prevented the deposit of lime-salts. Applying this observation, he has devised a tooth-powder in which the powdered talc is expected to prevent the deposit of tartar. The formula is:

Powdered talc.....	3	xv
Dried alum (or cream of tartar).....	3	i¼
Powdered cochineal.....	3	iiss
Essence of peppermint.....	gtt.	xx

The *Gaz. Hebdomadaire*, *Lancet* and other journals publish this formula without comment, but it seems important to add that there is hardly a substance so harmless to the teeth, next to mineral acids, as alum; and the fact that powdered soapstone is in very general use by mechanics as an ingredient of substances intended to prevent friction in machinery, does not promise much for its use as a polisher of tooth enamel. Besides these objections, what is to be said for the use of $2\frac{1}{4}$ drachms of cochineal?—*American Druggist*.

Powder Marks from Pistol Wounds.

Expert testimony was recently given as to whether a pistol discharged close to the body of a person would or would not leave powder marks. Positive opinions were expressed on both sides, and yet the question depends almost wholly on the kind of pistol and the kind of powder used and the amount of the charge. There is no rule on the subject, but in some weapons a thorough combustion of powder of a definite quantity and quality is secured, and in others the combustion is very imperfect, and on these conditions depends the effect of the discharge upon near surfaces. The experts, who ignored these conditions and testified about weapons and powder that had nothing to do with the case, simply told partial truths in the usual "expert" fashion. They testified with great confidence about matters which it is clear enough one or more of them knew very little about.

Vivisection.

A Parliamentary paper was published recently containing a report from inspectors showing the number of experiments performed on living animals during the year 1886 (under licenses granted by the act), distinguishing painless from painful experiment. The total number of persons holding licenses is 64 (48 in England, and 16 in Scotland), and of these 54 have performed such operations in 21 separate buildings, of which eight are in London, eight in the provinces, and five in Scotland. In all there were 81 experiments, in 19 of which anæsthetics were necessary.

The True Scientific Spirit.

Let those who think they know, without ever having looked to see, review their supposed knowledge and cast their thoughts over again; and if, in the particulars, they find they have mistaken words and fancies for realities, and accepted the dicta of pretenders instead of the evidence of observed facts, let them correct the record, and acknowledge the truth as it is in nature. Moreover, let them remember that he who propagates a delusion, and he who connives at one when already existing, both alike tamper with the truth, and that we must neither lead nor leave men to mistake falsehood for truth. Not to undeceive is to deceive.—DR. T. WHARTON JONES.

The Two Destroyers.

Once on a time a pious Moslem, saying
His morning worship in their style of praying,
Just as the early sun had lit the skies,
Beheld a phantom through the mist arise—
A phantom hideous as the dream of death.
"What art thou?" said the saint, with timid breath.
"I am the Plague."

"And wither tends thy race?"
"To slay ten thousand men in yonder place."
"Go not, I pray thee, if such prayer may be."
"In vain I am besought. 'Tis destiny!"
"Go, then, if Allah urge thy path of gloom,
Let the ten thousand know their sudden doom;
But in the prophets name I do implore,
When thou hast slain ten thousand, slay no more!"
"To hear is to obey!"

The vision passed,
And o'er a multitude its shadow cast.
After the plague was over, at the place
And hour in which it first unveiled its face,
Again the horrid phantom marched—and now
Outspoke the holy man, "Whence comest thou?"
"From yonder place."

"How many hast thou slain?"
"Victims of mine, ten thousand srew the plain!"
"Thou liest! There are twenty thousand dead!"
"Tis true," with feverish lips the phantom said.
"Full twenty thousand have death's power confest.
I smote ten thousand, fear struck down the rest."

—William D. Morange.

Diagnosis of Simulated Joint Trouble.

"I remember a funny experience I had during the war," said a leading physician; "I was up at Camp Dennison examining the conscripts, and many heart-rending pleas for exemption I had refused. One day a farmer, a German, a peaceable-minded fellow, who thought lots more of his turnips and cabbage than he did of military glory, was brought in to me. 'Doctor,' he said, 'I am not fit to go to the war, I am all crippled up with the rheumatism.' 'Where?' said I. 'In my right arm; I can only raise it yooost so high,' raising his hand about two inches from his body with great apparent effort. 'Well, you have got it pretty bad,' said I; 'you certainly can't go to war in that condition; how high could you raise your arm before you got rheumatism?' 'Oh, so high,' said he, raising his arm high above his head. That was just what I expected, and giving him a push I sent him along out to be sent to the war."

Why Beer is Bitter.

The bitter principle of hop has been investigated by Dr. Dreser (Arch. Path. and Pharm.), who confirms its character, previously established by Bungener, to be a crystalline acid insoluble in water, but rendered somewhat soluble by oxydation. The alcoholic solution of the unaltered acid is a powerful poison, 0.25 mg. being fatal to frogs, while 25 mgs. produced death when administered to a large guinea pig. It produces paralysis of the nervous system and the heart, but in mammals an intense acceleration of the respiration. In its changed form, a condition in which it is undoubtedly found in beer, however, it possesses no toxic effect, and may, therefore, as an ingredient in this dietetic agent, be regarded as harmless.

The Iodine Reaction for Starch.

Mylius has proved that *pure* iodine and *pure* starch do not produce a blue combination, but a colorless one; the blue color, however, at once comes into appearance if a trace of hydriodic acid be added. Usually the iodine of commerce contains traces of HI, hence the blue reaction is always obtained. If, however, the iodine is washed well with water, whereby the HI is removed, the blue color is not observed. Mylius analyzed the blue starch combination in a pure state and found it to correspond to the formula $(C_{24}H_{40}O_{20}I)_4 \cdot HI$; the molecular formula for starch would therefore be $= C_6H_{10}O_5)_4$, a result that corresponds with that obtained by Tollens in another way.

Such is Fame.

Literary eminence does not affect much lodgment in the minds of people of a certain grade. The other day, the *Listener* is told, a gentleman came into a barber shop just as Dr. Oliver Wendell Holmes was going out, and occupied the chair that the autocrat had vacated.

"Do you know who that was that just went out?" said the barber.

The visitor was curious to see what account of Dr. Holmes the barber would give, and shook his head.

"Why," said the barber, "that's old Dr. Holmes."

"And who is Dr. Holmes?"

"Oh, he's been a doctor here a great many years. I believe he ain't practisin' any more; but he's thought a great deal of!"

Mutual Confidence.

Judge (to the accused)—Seppel, if you admit that you owe your doctor 20 marks, and you have the money, why don't you pay him?

Seppel—I am perfectly willing to pay the doctor, but first he should give me a receipt for the money, for he is not a reliable man. If I give him the money before he gives the receipt, then he won't sign the receipt, and afterward he will want the money again.

Judge—Doctor, why won't you sign the receipt?

Doctor—I will tell your honor. Seppel is not a reliable man. If I give him a receipt he won't pay me at all, and if then I prosecute him he will show the receipted bill in court.—*Fliegende Blätter*.

Antiquity of Mercury.

Quicksilver, known to the Plinies and Dioscorides, was first authentically used by Avicenna and by Paracelsus. The first mention, however, of calomel we find in the seventeenth century, when it was known under various synonyms, such as aquila alba (the white eagle), leo mitigatus, drago mitigatus, panchymagogum, or mineral manna. It has held its own ever since, and is one of the first on the list of the present armamentarium.

Hygiene in Early Youth.

A three-year-old Philadelphian had heard her parents discuss hygiene until her infant mind was soaked with the subject. One day her dear old grandmother said—meaning to give Bessie a piece of cake—"Bessie, what do you always have after

your bath?" The child regarded her grandmother for a moment with inquiring eyes, and then replied: "Reaction."—*Christian Intelligencer.*

A Story of Science.

BY ONE WHO KNOWS NOTHING ABOUT IT.

A philosopher sat in his easy chair,
Looking as grave as Milton;
He wore a solemn and mystic air
As he Canada balsam spilt on
A strip of glass, a slide to prepare
For a mite taken out of his Stilton.
He took his microscope out of its case,
And settled the focus rightly:
The light thrown back from the mirror's face
Came glimmering upward brightly.
He put the slide with the mite in place,
And fixed on the cover tightly.
He turned the instrument up and down,
Till getting a proper sight, he
Exclaimed, as he gazed with a puzzled frown,
"Good gracious!" and "Highly—tightly!
The sight is enough to alarm the town—
A mite is a monster mighty!"
From 'tother end of the tube, the mite
Regarded our scientific.—
To its naked eye, as you'll guess, the sight
Of a man was most terrific,
But reversing the microscope, made him quite
The opposite of magnific.
"One sees the truth through this tube so tall,"
Said the mite as it squinted through it,
"Man is not so wondrously big after all,
If the mite-world only knew it."

MORAL.

Mem.—Whether a thing is large or small
Depends on the way you view it!

Dentistry in Germany.

There are at present 1,435 people engaged in dentistry in the German Empire. Of this number, 505 are "approved" in Germany, 33 of whom are American graduates. Of the 94 practitioners who are graduates of American colleges, only 17 are females; 21 are "approved" in other countries, but not in America. There are 815 persons practicing mechanical dentistry without any other occupation. In the province of Hesse-Nassau there are 83 practitioners of dentistry, of whom 29 are "approved" in Germany, 4 being American graduates, and 14 from American schools exclusively, 3 of whom are females. Two of these are "approved" in other countries (not America), and 38 mechanical dentists without other occupation. In 77 cities with over 10,000 inhabitants, there is not a dentist, surgical or mechanical, and in 86 cities there are no surgeons, though there are in these places practitioners of mechanical dentistry.—*Jour. f. Zahnheilkunde.*

Items.

—Dr. Negri, in the *Annali Di Ostetrica*, states that when the fetus is dead, if the examiner, while palpating the superior pole of the uterus, gives a series of little blows with the tips of the fingers, a cracking sound resembling the crepitus of fractures will be noticed.

—"Pears to me," said old Uncle Pete, as he leaned his hoe against the corn-crib and abstracted a pebble from his shoe; "pears to me like dar was some kin' o' mis-decomposishum in all dis talk about babies cuttin' teef. De way I'se cum to look at it, hit's de teef cuttin' de baby. Leas'wise, dat's de way hit looks in de case ob cullud chilren."—*Archives of Pediatrics.*

—Hippocrates employed a variety of medicines which, even at present times, are continually employed and held in high favor. Besides iron rust and hellebore, he was possessed of the knowledge of elaterium, colocynth, scammony, cantharides, asafetida, papaver somniferum, mandragora, and antimony. As prophylactics he made use of wine, vinegar, and kindred articles, and employed them for lotions and enemata, and for the same purpose they are still in use.

—The garbage crematory at Wheeling, W. Va., is said to be completed, and to have stood the tests which have been applied, to the satisfaction of the authorities. Pittsburgh, Penn., is also endeavoring to solve the difficult problem of the disposal of garbage, and has advertised for bids to construct furnaces. We regret to learn that the Milwaukee, Wis., authorities have decided to remove the garbage of that city to the country, and there bury it in the ground. Such a method of disposal is, at the best, unsanitary, and can be but a temporary relief.

—The Belgian Government, in consequence of requests made in the Chamber of Deputies, lately deputed three Belgian physicians residing in Paris—Drs. Grandjeau, DeBrun, and Peeters—to investigate and report on M. Pasteur's method of preventive treatment of hydrophobia, and to decide upon the advisability of founding a Pasteur Institute in Belgium. The report of these gentlemen, as the Chamber has just been informed, is decidedly adverse to such a step. It was decided by the reporters that Pasteur's method is not as yet sufficiently established, and one of them, Dr. De Bruyn, doubted whether there was any efficacy at all in the treatment. In this last view, Van der Corput, "Belgium's chief specialist," coincides.

—THE RIBERI PRIZE.—The Turin Academy of Medicine has selected for the Riberi prize of 20,000f. the following subject:—"Researches on the nature and prophylaxis of one or more of the infectious diseases affecting man." Manuscripts in Latin, French or Italian will be received until December 31, 1891. Printed essays will also be admitted to compete.

OBITUARIES.

MARK HOPKINS, M.D., LL.D.

It may not be generally known that the Rev. Dr. Hopkins, President of Williams College, who died last month, was a doctor of medicine. But such is the case. Mark Hopkins graduated in medicine, in New York, in 1829, and made an attempt to enter into practice by forming a partnership with Dr. Silas West, of Binghamton, N. Y. At that time Dr. West could not accede to the wish of Dr. Hopkins, and three months later the young physician was called to the Professorship of Rhetoric and Moral Philosophy in Williams College. This event diverted him from the practice of his profession and led him into the career which has been so honorable to himself and so useful to Williams College and to the world. Probably no college president has ever enjoyed more of the love and respect of his students than did President Hopkins, whose example and teachings were of the noblest sort. And, although he was but a short time in the ranks of the active members of the medical profession, it is a pleasure to believe that some share of his success may have been due to the ideas received during the period of his medical studies and medical work.

DR. BENJAMIN HANCOCK DEACON.

Dr. Benjamin Hancock Deacon, of Frankford, Philadelphia, died at his residence on May 20, 1886, from general paresis. Born in 1810, in Burlington County, near Burlington, N. J., he graduated at the Jefferson Medical College, in 1845, and soon after engaged in practice in Delaware County, Pa. Four years later (1849) he removed to Frankford, and with the exception of the year 1873, when he made a trip to Europe, was in constant practice until 1883, when he declined to visit patients outside, and prescribed for but few patients at his office. However, after the summer of 1884, he generally declined to write prescriptions, and devoted his time largely to reading and his private affairs.

Dr. Deacon was a member of the Society of Friends, a director in the Second Nation Bank, a director in the Board of Friend's Asylum, and for several years visiting physician to the same. In conversation a year before his death, he spoke of his early struggles, and said he was in Frankford more than three years before he had acquired a respectable business, but we have learned from physicians younger than he that later on he had a large and lucrative consulting practice.

This epitome of nearly forty years' practice of medicine fails to fully record the history of a life well spent, nor does it express the grateful feelings of a large and appreciative circle of patrons.

Official List of Changes of Stations and Duties of Officers.

Changes in the Medical Corps of the Navy, for the week ending July 2, 1887:

P. A. Surgeon, C. W. Deane, ordered to the Naval Rendezvous, San Francisco, Cal.

Asst. Surgeon, H. N. F. Harris, ordered to the Naval Hospital, Mare Island, Cal.

Med. Director, A. G. Gorgas, remain on present duty until Dec. 31, 1887.

Med. Inspector, C. J. Cleborne, remain on present duty until Dec. 31, 1887.

Surgeon, Benj. F. Mackey, remain on present duty until Dec. 31, 1887.

Med. Director, J. Mills Browne, will remain on present duty as member of Retiring Board until June 30, 1888.

Med. Director, Richard C. Dean, will remain on present duty as member of Retiring Board until June 30, 1888.

Official list of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from June 26, 1887, to July 2, 1887:

Major J. C. McKee, Surgeon, granted three days' leave. S. O. 149, A. G. O., June 29, 1887.

Capt. George T. Beall, Medical Storekeeper, granted four months' leave of absence. S. O. 150, A. G. O., June 30, 1887.

Capt. A. V. Cherbonnier, Medical Storekeeper, directed to take charge of office and perform duties of Acting Assistant Medical Purveyor in St. Louis, Mo., during absence on leave of Capt. Geo. T. Beall, Medical Storekeeper, now performing those duties. S. O. 150, A. G. O., June 30, 1887.

Armstrong, S. T., Passed Assistant Surgeon, relieved from duty at Marine Hospital, Memphis, Tenn.; ordered to Marine Hospital, New York, N. Y., June 27, 1887.

Beckham, C. T., Passed Assistant Surgeon, relieved from duty at Marine Hospital, Wilmington, N. C.; ordered to Marine Hospital, Memphis, Tenn., June 27, 1886.

Glenan, A. H., Passed Assistant Surgeon, ordered to Revenue Cutter "Crawford" for temporary duty, June 30, 1887.

Brooks, S. R., Assistant Surgeon, ordered to examination for promotion, June 27, 1887; relieved from duty at Evansville, Ind.; ordered to Marine Hospital, Wilmington, N. C., June 27, 1887.

THE MEDICAL AND SURGICAL REPORTER

No. 1585.

PHILADELPHIA, JULY 16, 1887.

VOL. LVII.—No. 3.

ORIGINAL DEPARTMENT.

LECTURE. OBSTETRICS.¹

BY SAMUEL WOLFE, M. D., OF SKIPPACK, PA.

MR. PRESIDENT AND GENTLEMEN:

In a letter which appeared in the March number of the *American Journal of Obstetrics*, Prof. Saenger describes a number of distinct forms of salpingitis, each with a definite cause, thus differing from those who hold pyo-salpinx to be always due to gonorrhœal infection. Among other forms he describes a salpingitis septica, corresponding to varieties of puerperal disease, which are ascribed to sepsis. According to his view, not only after labor at full term, but also after abortion or premature labor, a woman is liable to contract this form of the disease, as a concomitant of that form of acute septicemia from which she may happen to suffer. He says: "Salpingitis septica, co-existing with severe puerperal septicemia or 'lymphatic peritonitis,' has never as yet, it is true, given the surgeon an opportunity to remove the principal focus of the disease by extirpation of the tubes. It is possible, however, that under certain circumstances such a procedure might be indicated." After relating two cases in which the tubes had burst from over-distention of pus, and which ended in death, one on the fourth and the other on the twenty-first day after confinement, he adds: "Cases of this kind will be diagnosed more frequently and more readily as soon as

our attention has been called to them, and we may then expect to hear of their treatment by operation."

This letter appeared, as above stated, in March, 1887. On the 14th of February, Dr. D. Longaker, of Philadelphia, had removed the right tube in a case delivered nine days previously, in the twenty-ninth week of gestation. As this case has not to my knowledge been fully reported, I insert here the following notes obtained from Dr. Longaker:

"The patient was twenty-three years old, and single. She was a robust woman, of large frame, and had always enjoyed good health. She had never had dysmenorrhœa. Early in January, 1887, she had a profuse discharge, like that of acute gonorrhœa. She was well advanced in the sixth month of pregnancy. On February 5th, a twenty-eight weeks' male fetus was born. The woman did fairly well for four days, when she complained of pain and tenderness in left inguinal and hypogastric region. Her tongue was dry; her pulse, 96; her temperature, 102° in the evening. Seven days after delivery she was attacked with intense pain in the left inguinal region. A few hours after the onset of the severe symptoms, her temperature was 96.5°; her pulse, 96; her respiration 24; her knees drawn up. A diagnosis of peritonitis was at once made. Dr. Joseph Price saw the patient a few hours later, and we agreed upon the advisability of laparotomy. Owing to an apparent improvement in her condition, I allowed myself to be persuaded to postpone this for about forty-eight hours. At this time it was evident to all that she would die unless relief came speedily. She readily assented to the operation. On open-

¹An Address delivered before the Medical Society of the State of Pennsylvania, June 30, 1887.

ing the abdominal cavity, general peritonitis was evident. The uterus was fairly involuted. As the intestines were raised from the region of the left cornu uteri, a large amount of stinking pus was discharged—possibly a pint. The left Fallopian tube, the size of a thumb, was removed. The uterus was fixed in the pelvis by peri-uterine inflammation. The right tube was not disturbed. Irrigation with hot water, arrested the hemorrhage. The wound was closed with Chinese silk, and a drainage tube inserted, and the patient reacted promptly and did well for twelve hours, when vomiting set in, and continued until her death, thirty-six hours after the operation.”

On the 5th of March, Dr. J. M. Baldy, of Philadelphia, operated on a similar case, (see next week's *REPORTER*) the patient making a good recovery. This was first case of the kind in which life was saved, and also the first case reported, and therefore entitles Dr. Baldy to priority.

Some difference of opinion exists in regard to the origin of these cases, some holding that the tubal disease is always the result of the gonorrhoeal virus having found its way at some time to the tubes, producing chronic disease there, and under the influence of the puerperal state, being transformed to an acute and violent disorder. Others again believe the puerperal condition may alone be, under the influence of sepsis, chargeable with its origin.

Dr. Baldy believes that it may arise as an acute disorder, in one confinement, may subside into a chronic form (or be even latent), and in a subsequent lying-in again revive and go on to a fatal result, if not promptly recognized and treated by operation.

Thus, in our own State, and within the past year, a great practical advance has been made in the treatment of what is usually called puerperal fever.

A class of cases is provided for which would probably disappoint the most methodical and thorough application of the antiseptic system. If an old salpingitis, due to a former labor, to an old gonorrhœa, or to any other cause, exists, the most rigid observance of antiseptics will hardly exempt from troublesome sequences to parturition. It is true that many believe conception to be impossible, or at most extremely rare, where a tube is diseased; but this view is strongly opposed by others.

However this may be, it seems likely that an era has been inaugurated, in which the indications will be plain, in the small percentage of puerperal diseases which seem not

amenable to the thorough antiseptics of the present day; and to Pennsylvania will belong the honor.

On antiseptic midwifery much has been written, and the details are well worked out. The works of Garrigues² and Richardson³ leave but little to desire, on the part of those who incline to carry out, either in hospitals or private practice, a complete system. Their ground is well supported by logical argument and scientific facts, and with the aid of Dr. Hirst's monograph on “The Death-rate of Lying-in Hospitals in the United States,”⁴ these works make a strong presentation of the subject.

It is, indeed, at present, more a question of antiseptics than of asepsis. The existence of sepsis is hardly denied by any authority, although Saenger accuses Tait of standing in this position. He says:⁵ “He (Tait) does not believe in sepsis at all, does not believe in infection, denies the principles on which modern surgery and obstetrics is based. He has been taught nothing by the researches of Semmelweis and Lister, Pasteur and Koch.” This being written in the warmth of a reply to an attack by Tait on Saenger, may not be a fair statement of Tait's views, for, as Marcy says: “The most scrupulous Listerian disciple cannot outvie Mr. Tait in enforced cleanliness. His sponges are an especial care and just pride, while no operator more carefully removes the very material, too often left in the pelvic basin, which will serve as food for bacterial development.”⁶

Sepsis being admitted, asepsis must be secured, and the problem lies in the method. Whether by a system which aims at a certain destruction of all manner of germs, by chemicals known to be capable of exercising such an effect, or by physical or hygienic methods which will insure their exclusion, is probably more a question of taste than of belief.

When the choice of germicides is to be made, so far as experiment has demonstrated their virtues and practice acquainted us with results, we would hardly find it necessary to consider more than two drugs, the bi-chloride and the bin-iodide of mercury. The former has an extensive history as a germicide, while the latter has been brought to the notice of the profession by Dr. E. P.

Bernardy,⁷ of Philadelphia.

The claims for it, over sublimate, are, greater germicide properties in weaker solutions, and lesser irritation and danger of poisoning. Recent experiments by Dr. P. K. Bolshepol'sky,⁸ of St. Petersburg, fully confirm the observations of Dr. Bernardy.

Other substances have been brought forward, each having some advantage or some special application urged for it, amongst which are boracic acid, alcohol⁹ by Dr. Paramore, of London; carbolic acid, thymol and iodoform¹⁰ by C. Braun, of Vienna.

As to the extent to which antiseptic precautions shall be practiced, there are those who think it unjustifiable, and some even criminally negligent, to treat any case, at any period, either during labor or the lying-in period, without the adoption of a full line of these tactics. Others again, and among these are many whose opinions are entitled to great respect, believe that the practice in hospitals and private may largely differ, the precautions necessary in the former being to a large extent not only unnecessary and superfluous, but even liable to work injury in the latter. Distinctions between city and country practice are also made.

There are many shades of opinion as to what constitutes a complete system of antiseptis. Bearing on these points, I will read a few references which, though drawn partly from the field of abdominal or general surgery, and in other instances relating only to intra-uterine injections, or some special part of the antiseptic plan, yet have their application here.

Dr. Graily Hewitt says:¹¹ "The practice of midwifery in private and in a lying-in hospital cannot be looked upon as identical, so far as the frequent use of antiseptic injections is concerned. . . . If it went about that the internal injection of a dangerous antiseptic, such as corrosive sublimate, was essential to the safety of the lying in patient, it would be the cause of infinite mischief. No doubt in a lying-in hospital extreme precaution is justifiable, but in private practice less dangerous materials can be employed, and frequent use of injections cannot be held to be necessary."

Dr. Champneys says:¹² "Private practice and hospital practice differ in one respect;

in both the patient requires protection from the accoucheur and nurse; but the latter also requires protection from other patients. We must balance the risk of sepsis against the risk of mercurialism, and I unhesitatingly embrace the latter."

Dr. John Phillips says¹³:—"The question of intra-uterine injections is sub-judice. As regards vaginal injections of sublimate, they might be safe, if there are no lacerations, not otherwise."

Dr. Sutton says:—¹⁴ "If Listerism has taught us anything, it is cleanliness in surgery." "It is clearly proven that a specific dressing to every wound is unnecessary, and also that specific dressings fail in the object intended." "He (the surgeon) must always keep before him, the fact that no system of antiseptics, will cover dirty and slovenly surgery."

Dr. Hiram Corson says¹⁵:—"It (puerperal fever) is a disease exceedingly rare in the country. If it is caused by the germs which are so guarded against in cities, and especially in hospitals, they are inactive, if they exist at all, in the country; and therefore, the directions so urged by Dr. Elliott and Carl Braun, and others, are not needed with us."

Dr. Joseph Price says¹⁶:—"Distance dirt and all will be well."

Dr. Hirst,¹⁷ in the Maternity Hospital, in Philadelphia, and in his private practice, carries out a plan by which 210 women have been delivered, without a death, which consists of the usual disinfection of hands, &c., with sublimate solution, a blanket previously soaked in a 1 to 2000 solution, and dried, on which the woman lies, and a regular system of ablutions of the external genitals with a 1 to 2000 solution. In the hospital a routine 1 to 4000 injection is given from a fountain syringe, immediately after the close of the third stage of labor.

Dr. Longaker,¹⁸ while believing in great precautions, thinks injections should be restricted to cases in which some obstetric operation, such as version, forceps, craniotomy, had been performed, and then the iodoform pencil should follow the injection, which should have been intra-uterine. He says injections "are unnecessary in normal cases, and may do harm." He regards the occlusion dressing of Garrigues as indispensable

in hospital, but in private practice finds he "gets along as well without it."

The annual reports of the Philadelphia Dispensary, for the years 1883, 1884, 1885, and 1886, show a total of 810 confinement cases attended from that institution, all at their homes. These homes, it is not necessary to state, were, for the most part, in the most unsanitary condition in every respect. If I have been rightly informed, and I have taken pains to be, no antiseptic precautions were taken in any of these cases, and yet there was not a single death amongst them. From private sources, I learn, that the cases which have occurred during the present year, up to May, at least, have also been without mortality. The grand total, therefore, comes near reaching that of Tarnier (1000 cases), and the result—"without a death"—is more remarkable, since the attendants were largely young men, with but little experience.

I have no desire to underrate the intelligence and progressive spirit of country practitioners. I would rather believe them to be, after the exclusion of the great teachers and leaders of medical thought, the peers of their town *confrères*. But from what I know of them and of country practice, I am doubtful whether the earnest plea of Garrigues to them, to adopt the antiseptic system, or any other argument that can be made, will prevail with the great majority of the present incumbents. It may be as Marcy says, that the men who are now receiving their education, and who are having the principles of the antiseptic method thoroughly ingrained upon them, will successfully introduce it. There are many reasons, pertaining both to the practitioner and his patrons, which make it unlikely that there will be the radical change which would occur under the new system. Though they may not be regarded as sufficient by those who advocate the latter; they will have accomplished their purpose, when they are sufficient to those contented to practice under the old order. They are in fact more weighty than those who have never practiced in the country can comprehend, and I am of the opinion that many hundreds of positions might be found in Pennsylvania alone, which if filled for one year by ardent exponents of the antiseptic system, would convince them, that their predecessors were entitled to some little justification in letting the traditional one in one hundred die of sepsis.

They but seldom are engaged in advance to attend patients in confinement, and have therefore no opportunity to arrange the preliminaries. They are often called just in

time to support the head as it is passing the external outlet, and making solutions, and soaking the hands for five minutes at this juncture, before touching the patient, would not be likely to be thought very fitting. And yet it is risky to the reputation of a country practitioner not to go through the same routine in every case, as his patients are constantly associating with each other and comparing notes. Then again if the idea was fostered that there was danger at every point in a midwifery case, the hopeful spirit which we all so much value would be violently disturbed, and nowhere so much so, as in the simple-minded, self-engrossed, country woman. The nursing, too, is hardly as intelligent as that which is commanded in cities; and far less so than that in hospitals. The accoucheur seldom sees his patient more than twice after the day of labor, and must content himself with a very small fee for even so small a service. Moreover he has been going on for years, probably, without a fatal or even a seriously ill case, and is not likely to be terrified into a radical change of his methods by collective statistics, which are drawn from very remote sources. "Letting good enough alone" is apt to be a stubborn principle with him.

The admitted dangers of poisoning are likely to have considerable weight, and that these dangers would be greater in the hands of the busy practitioners and ignorant nurses, under whose care after all the great majority of puerperal women find themselves, than they have been under the management of the skillful class of practitioners to which the antiseptic practice has been thus far mainly confined, is hardly to be contraverted.

Dr. Lucien Butte reports, in a recent number of a French journal, some twenty cases in which the employment of sublimate had caused death. Doleris and Butte, in December, 1886,¹⁹ publish their conclusions from a series of experimental researches, under four heads, the fourth reading thus: "In the face of its possibly dangerous results, it is questionable if sublimate should be used in obstetrics and gynecology."

If then for some time to come, antiseptic midwifery mainly remains confined to hospitals, and to the private practice of those connected with them, and to those whose consciences will not rest unless they are steeped in sublimate solution, we should not cry homicide and malpractice on the poor man who dares to make a vaginal examina-

¹⁹ *Nouv. Arch. de Gynéc.*

tion without the "strictest antiseptic precautions."

In the treatment of mastitis, the old system of breast-pumping has given way to equable pressure by a bandage, supplemented in severe cases by the application of the ice-bag. The treatment of inflammatory diseases of any organ by cold has long had an able advocate and exponent in Dr. Hiram Corson, of Conshohocken, and to bring forth anything that is new to him in this line would probably severely puzzle the scientific world.

Antiseptic midwifery applied to the breasts in the manner taught by Garrigues, it is claimed, will prevent the occurrence of mastitis, and antiseptic surgery adopted in the treatment of mammary abscess, will very speedily cure.

Dr. Longaker, in an article on this subject ²⁰ reaches the following conclusions:

- (1) Milk retention is not a cause of mastitis.
- (2) Milk retained in an inflamed breast does no harm.
- (3) Any effort to remove the secretion increases the intensity of the inflammation by stimulating the functional activity of the gland.
- (4) The fundamental principle to be observed in the treatment of mastitis is rest. This will prevent suppuration.
- (5) In suppuration, early incision, under antiseptic precautions and drainage, is to be strongly urged.

A correspondent of the *British Medical Journal* advocates for inflammation of the breast "effervescing citrate of potash, with about fifteen minims of sweet spirits of nitre and the same quantity of sal volatile every four hours." To ease pain and help resolution, he advises hot fomentations containing belladonna.

Mr. Miall ²¹ says: "When mammary abscess is on the point of forming, I have frequently seen all the symptoms rapidly disappear in a few hours under the influence of fomentations with hot water and carbonate of ammonia, an ounce of the carbonate to a pint of water." The nipples must be protected.

I have seen good results from the liberal use of an ointment of calomel (3j—3j), conjoined to appropriate internal treatment and care of the nipples, with an efficient sling for the inflamed organ.

Touching the value of support to the perineum, Dr. Bahnson, of Salem, N. C., gives

in a recent article ²² his opinion of the cause of lacerations, and his method of preventing them, which he regards as superior to other procedures. He does not believe that the head causes the laceration, but ascribes it to the cutting of the acromion which ploughs over the perineal floor. The opinions expressed by Dr. Baldy ²³ also make it doubtful whether we are doing all for the woman, that we are apt to fancy we are, in supporting the perineum. He says "if we hold the head back, the vis à tergo must be spent somewhere, and that somewhere is the pelvic floor." He points out that the skin is frequently intact, while the structures internal to the skin, forming the posterior vaginal wall, are torn and prolapsed, a condition for which operative procedures become necessary.

The idea of the hand on the perineum at the moment of the passage of the head over it, is, in my mind, not to prevent the head from moving forward, but to secure its direction in conformity with the natural curve of the distended, but not torn, perineum. The unsupported parts may not furnish sufficient resistance, and may, under a sudden force, give way, an accident probably less likely to occur when a tactus eruditus is in requisition.

Lanolin has been brought forward ²⁴ as far preferable to lard or any other unguent, for overcoming rigidity of the perineum.

While we are aiming at the prevention of lacerations, the Burmese midwife, according to Dr. T. F. Pedley, of Rangoon, ²⁵ in primipara, tears the perineum with her thumb-nail, which she has cultivated into a long and sharp instrument for this very purpose; or if not furnished with this terrible tool from her hand, she is sure to have it on her great toe from which position she wields it with equally effective fiendishness.

And finally, in regard to this caption, I have somewhere seen a case reported, in which the accoucheur's attention was called to something being expelled from the rectum, as the head was descending, and finding it to be a sausage several feet in length, which had been placed there to insure expulsion of the product of conception by way of the natural outlet.

In the March and April numbers of the *American Journal of Obstetrics*, for this year, Dr. King, of Washington, brings forward a new and very interesting theory on the cause

of the renal troubles of pregnancy. He maintains the normal position in utero to be oblique, with the pelvic extremity towards the one side, usually the right, and the cephalic towards the other, resting in the iliac fossa, above the pelvic brim. So long as this position is preserved the large abdominal vessels escape pressure; when it is changed to the vertical, which may occur from numerous causes, compression occurs, and renal troubles, with all their serious consequences appear.

The electric shock, for the destruction of the life of the fœtus, in extra uterine gestation, in the early months, has become the recognized treatment for that condition, although laparotomy too has its advocates, amongst whom is Gallabin, whose work on obstetrics has appeared within the year.

Among the other new works, are those of Parvin, King, Mundé and Charpentier.

While I recognize the imperfection of this sketch, and feel that what has been done within the year, to which no reference is made, may far exceed in importance that which has been noticed, without, however, any intentional slight, I may yet hope that I have brought this subject before you in such a way that you may see that the march of progress has been rapid; that the great art of midwifery has gained in useful acquisitions; that the diseases of the mothers of our time are being sedulously studied; and that what was an obscure art, still allowed to smoulder under ignorance and superstition, when the other departments of medicine had long since emerged from the darkness of former ages, is now amongst the most finished of the specialties, and the one which probably leads in the application of the most advanced principles of practice.

—“The Uses of Adhesive Plaster in Orthopædic Surgery” is discussed in a very clear and practical way by A. B. Judson, M. D., of New York. The pamphlet before us is reprinted from *The New York Medical Journal* of June 4, 1887.

—Dr. Henry Boynton, of Woodstock, Vt., in a recent address on alcohol and opium, said that the use of opium was increasing in that locality. The four druggists report sales of opium in a year sufficient to make one hundred gallons of laudanum. This is the equivalent of one hundred and sixty-seven ounces of morphine. Of this whole amount only *five per cent.* is sold to physicians.

COMMUNICATIONS.

THE USE OF THE EXPECTORANTS IN THE PULMONARY DISEASES.

BY J. CHRIS LANGE, M. D.
Prof. Principles and Pract. Med. at Western Pennsylvania Medical College, of Pittsburgh.

It is the object of this paper to present some considerations upon the customary employment of the expectorants in the treatment of pulmonary diseases. The term, expectorant, is applied in the *Materia Medica* to a class of remedies the effects of which are said to embrace a modification of the condition of inflamed mucous surfaces, as a result of which their secretion is increased in quantity and decreased in viscosity; in other words cough is “loosened” and expectoration is facilitated. Senega and scilla, classed in the *Materia Medica* as blennorrhethics, and ipecacuanha and sanguinaria, of the class of emetics, are the substances some preparation of one or more of which most frequently constitutes the potent ingredient of the conventional cough mixture. Such a mixture is commonly exhibited in diseases accompanied by cough; that is to say, in pulmonary diseases. In this class of affections a cough mixture is a clinical necessity. Patients demand a medicine addressed directly to the most prominent symptom of these affections, namely, to the cough. Very frequently the only indication for treatment which exists in such cases is the exhibition of some remedy to allay the cough. As a consequence of this demand and of this indication, it is almost universal practice to administer in such diseases some compound or mixture containing a preparation of ipecacuanha, scilla, senega, sanguinaria, or some other of the expectorants.

It is proper to ask, therefore, upon what grounds this common practice rests? Are these grounds good and sufficient? Is this practice based upon the results of clinical experience, or is it supported alone by the arbitrary and fallacious classifications of the *Materia Medica*?

The natural history of the most common of the pulmonary diseases, acute, simple bronchitis, embraces a duration of from ten to twelve days. It may be divided into two stages; during the first stage, a period of from three to five days, the sputum is transparent, scanty and viscid; during the last stage the sputum becomes abundant, opaque and muco-purulent. This is the expectoration of acute simple bronchitis

when the disease pursues its course untreated. I have many times verified it and have records of many cases. If now the described desirable effects of the expectorants follow their administration, they should be appreciable in the comparatively simple inflammation mentioned. That is to say, in other words, the first stage of an acute simple bronchitis should be shortened, or, if you please, the duration of the affection should be shortened. If this putative effect of the expectorants obtains, the stage of scanty and viscid sputum should not endure so long, and the stage of free expectoration should appear earlier than is the rule in cases untreated. Does this result follow in cases treated by the expectorants? I have records, also, of many cases of acute simple bronchitis treated by the expectorants; a comparison of my record of cases so treated with that of cases entirely untreated demonstrates the result of the administration of the expectorants in this inflammation to be *nil*. This comparison shows no diminution in the duration of the first stage, and no diminution in the duration of the affection. In my experience, therefore, the reputed action of the expectorants in acute simple bronchitis is merely a superstition. The disease runs its course precisely as though untreated. In consequence, my employment of these remedies would rest, not upon good and sufficient grounds, not upon the results of clinical experience, but upon a fallacious classification of the *Materia Medica*, and upon custom which makes laws by no means invariably wise. And the same is true of my observations regarding laryngitis, pleuritis, and pneumonitis; these affections run their course uninfluenced by the administration of the expectorants. If these affections run their natural course, if their cough is uninterrupted, uninfluenced by the administration of these remedies, then despite a therapeutic legend, the usefulness of the expectorants in these inflammations is not warranted by clinical experience.

The study of the effect of the expectorants in chronic diseases of the pulmonary structures abounds in difficulties which are absent from that of the acute diseases. It may be aphoristically said that the intensity, duration and frequency of cough is in proportion to the difficulty of expectoration; and that this latter is in proportion to the scantiness and viscosity of the sputum. The cough mixtures, of which the potent ingredients are the expectorants, are addressed directly to the cough; they are administered for their putative action, the modi-

fication of the inflamed mucous membrane, resulting in a sputum increased in quantity and decreased in viscosity. That is to say in other words, they are administered to "loosen the cough." The question to be answered is, does clinical experience demonstrate that this effect follows the administration of the expectorants in the chronic pulmonary diseases?

The difficulties to answer this question are many. They are the ever-varying conditions of the sputum, as to quantity and viscosity, which belong to the natural, as well as to the clinical history of these affections. The intrinsic causes productive of these varying conditions, are the changes involved in the progress and retrogression of these diseases, and in their complications. The extrinsic causes active to the same end are innumerable; prominent among them are atmospheric changes as regards temperature, humidity, and direction of the wind, and changes in the life and habits of the patient. Other difficulties emanate from the desponding or hopeful or petulant patient; the subjective descriptions of cough and sputum, the subjective certainty of improvement or decline, of restoration or destruction. Superadded to these difficulties are those generated by the unscientific conclusions of the physician, whose laudable desire to be useful, whose veneration for time-honored and unquestioned propriety, are prone to picture to him good results where none exist, and to make natural changes appear as consequences of his therapeutics. These difficulties beset the way of the clinical investigation of the effects of the expectorants in chronic pulmonary diseases. They constitute effective bars to entrance into, and exploration of, this field,—bars unsurmounted and yet unsurmountable. Therefore, to the question: Does clinical experience demonstrate that the putative good effects of the expectorants follow their administration in chronic pulmonary diseases? we have to answer: This is still undetermined. And from this it follows that the customary exhibition of the expectorants in these affections rests, not upon results of clinical experience, but upon an honored classification of the *materia medica*.

Let us consider other effects of the expectorants. They increase the action of the skin and that of all secretory and excretory glands. In other words they effect a derivative revulsion: they produce a plethora of the abdominal viscera, the glands and skin, and a corresponding anæmia of the thoracic

viscera. Is this action of the expectorants desirable in the pulmonary diseases? There is no clinical evidence to prove this action a beneficial one in the acute pulmonary affections; there are grounds to justify the belief that, in chronic pulmonary affections, this action is an unfavorable one. The chronic pulmonary diseases embrace in their morbid anatomy blood stasis, œdema, infarction, hypertrophy, atrophy, degeneration, abscess, necrobiosis, etc., processes and conditions which have to do, not with an increased blood supply, but with a blood supply which is diminished. The presence of the greater than normal quantity of blood in the pulmonary structures is not an active congestion, like that of the first stage of a croupous pneumonia, but a passive one like that of a protruding hemorrhoid. Such processes and conditions thrive upon a diminution of the arterial blood supply, for the reason that this involves the presence of an increased quantity of venous blood. In short, as stasis is increased by a diminished arterial supply, and as stasis is a factor, as well as a cause and an effect, of the destructive processes and conditions constituting chronic pulmonary diseases, its diminution instead of its increase should be the object sought to be attained by treatment. From this consideration a rational conclusion, repeatedly proven correct by clinical experience, is established. It is that, in chronic pulmonary diseases, derivative revulsion is an injudicious measure of treatment; that it is a depressing measure; and that its results, like those of all antiphlogistic treatment, are bad.

If this effect, the diversion of blood to other parts, is desirable or is desired in any case of pulmonary disease, other remedies than the expectorants will produce it much more energetically; but it is not for this effect the expectorants are employed; this effect is secondary, minor, incidental only, and quite unimportant. This effect has not established and does not maintain the customary exhibition of the expectorants. This is accomplished solely by their putative action, to increase the quantity and to decrease the viscosity of the sputum,—to “loosen the cough.”

Finally, we have to consider one other action of the expectorants. This, also, is an action, which has not established and does not maintain their customary exhibition; this action, also, is secondary, minor, incidental only, and receives no attention.

This effect is nausea. Nausea is a powerful antiphlogistic. A nauseated patient is

subjected to a potential modification of his nervous system, which breeds disturbances throughout the whole economy. This is manifested by a thready pulse, a cool surface bathed in clammy sweat and cold extremities, by pallor with bloodless prolabia, and a relaxation of the whole muscular system, including often the sphincters. In the nauseated patient life appears to be at its end. Nausea is one of the most energetic immediate sedatives, to which free bleeding alone can be compared. This is nausea to the point of emesis. It is not this point, however, which is reached in the administration of the expectorants, excepting those instances in which it is desired to vomit the patient; the exhibition of these remedies does not reach this point of nausea. Pronounced nausea is not produced by the proper dose of an expectorant, or if it be, the dose is diminished. Nevertheless, a degree of nausea is a result of the employment of these remedies, and this is more or less manifest according to the size of the dose and the susceptibility of the patient. The administration of expectorants results in a degree of nausea, the existence of which is readily appreciable in the physiological state; in the pathological state its existence is most obviously made manifest by the destruction of an already impaired appetite, by the substitution, for a limited power of taking nutriment, of loathing for all food. This I have frequently verified by the alternate administration and withdrawal of these agents in the same patient. Further, by the exhibition of the expectorants to healthy persons, some malaise, a pasty mouth, a furred tongue, complete anorexia, and epigastric tenderness, are produced in the course of a very few days. These symptoms belong to the physiological effects of the expectorants; these symptoms also constitute the semiology of a mild sub-acute gastritis. The obvious inference is that the latter affection is a consequence of the exhibition of the expectorants.

Let us apply these considerations to the management of pulmonary diseases. Are these depressing and spoliative effects desirable, let us ask, in phthisis? An answer is obviously unnecessary. Yet what is more common than to administer some cough mixture containing an expectorant, during the course of this affection? It is expedient, a matter of course, routine. An indication exists for, and the patient demands, some remedy addressed directly to the cough; the time-honored expectorant is chosen; its putative expectorant effect is of such import-

ance that its perturbing and spoliative effects are forgotten or ignored.

Equally injudicious is this treatment when employed in chronic bronchitis. An affection which frequently entails upon the patient a dilated heart, and the pathological changes of which depend largely upon blood stasis, contra-indicates the exhibition of every agent which numbers among its affects a sedation of the heart and a diminution of nutritive supplies. The consequences of such a remedy, though they may be long endured, and though they may be difficult to measure, are certain to follow its administration: they are debilities which in and of themselves may be effectual bars to a recovery. Yet more pernicious is this treatment when employed in the pneumonia of old age, which disease is frequently a process of chronicity. As a disease imperatively requiring, above all else, most energetic supporting treatment, one in which all depressing measures are clearly contraindicated, its proper management debars the use of the expectorants; and if these remedies enter into its treatment this therapeusis deserves the title which its result confers upon it.

The exhibition of the expectorants in the acute pulmonary diseases which are without danger to life can be objected to only on the grounds that their expectorant action is observed to not follow their administration, that their revulsive action is too feeble to be of service, and that as nauseants the worst they accomplish is to increase somewhat the patients' discomfort and debility. If our therapeutic resources do not embrace a better treatment for the cough of an acute simple bronchitis, for instance, then no more potent objections than those cited may be made to the administration of expectorants, perhaps; and yet it is conceivable how, particularly in the young, the old and the feeble, this treatment may be a causative factor in the extension of a bronchial inflammation which terminates in catarrhal pneumonia. It is conceivable how the depressing effects of expectorants may constitute the essential, because the necessary, factor which induces an extension and prevents a resolution of inflammation; how these effects may constitute the metaphorical feather which breaks the camel's back. If this be true it is a grave objection to this treatment which must be added to the trivial ones.

In another class of acute pulmonary diseases, namely, those in which danger to life is by apnoea only, the trivial objections to the employment of expectorants can alone be urged, provided this treatment is not

allowed to displace proper and more energetic measures. In such affections we are not concerned with asthenia; we know the patient to be safe as far as exhaustion is concerned; hence no grave objection to the use of the expectorants exists, and the trivial ones are only to be remembered. These objections become potent however in all acute pulmonary diseases in which the danger is from asthenia. That is to say in other words, in all such diseases in which, if they end fatally, death is caused by the exhaustion of the patient. A class of diseases of which Dr. Flint has said, "The ending is a question to be decided by the tolerance of the patient; if his tolerance hold out, the ending is in recovery; if it do not, the ending is in death." This class embraces the majority of cases of acute pulmonary diseases, and their proper treatment presents this pre-eminent indication, to strengthen and to lengthen the tolerance of the patient. If the tolerance of the patient hold out the ending is in recovery; if it do not the ending is in death. The tolerance of a patient is not strengthened and lengthened by the exhibition of the expectorants, but is, on the other hand, weakened and shortened by it; and, again, it is conceivable how this weakening and shortening, be it ever so limited and difficult to measure, may constitute that factor in a case which determines a fatal ending.

TRUE AND SIMULATED INSANITY IN THE CRIME CLASS.

BY DR. WM. DUFFIELD ROBINSON,
Physician in Chief of the Eastern State Penitentiary.

Abstract of a paper read before the Philadelphia
Neurological Society.

In the general population there is a distinct class known as the "*Crime Class*," and most State Prison offences are committed by this class. They seldom reform, but end in death, lives passed in crime and infamy. They have as little control of their natural inclination to wrong doing as a drunkard has over his desire for liquor. They are seldom given to rum-drinking and rarely permit themselves to become intoxicated. They have little sense of honor among themselves, and see little, if any, moral wrong in their crimes, regarding the man who brings them to justice as worse than themselves. They do not believe in sexual purity, and are given to excessive venery. They squander their money when they have it, have little fear of death, and in many cases are infidels. They form strong

but capricious and unstable attachments. The class includes persons of all grades of intelligence and education. With them crime is a monomaniacal infatuation. They are distinguished by abnormal shrewdness and cunning, either inherited or developed by life-long practice in evading detection. Each devotes himself for life to his own special line of criminal work.

As a class they are deficient physically and mentally; 20 per cent. have had syphilis before they are 40 years old; neurotic diseases are common among them; they are frequently the subjects of epilepsy, and mental diseases prevail among them in a far larger proportion than among the general inhabitants. Fully 10 per cent. develop some form of mental disease before death. Three or more deaths from tubercular diseases occur in a family in $76\frac{1}{4}$ per cent. of such convicts.

The criminal tendency of individuals of this class is almost always inherited, and they have scarcely any control of it.

About 6 per cent. of convicts show a strong inherited tendency to insanity, and over 17 per cent. of the convicts in the Eastern Penitentiary of Pennsylvania show family crime histories. Where two or more members of a family are convicts, they almost invariably show the distinctive characteristics of the crime class.

During the five years I have been physician to the Eastern Penitentiary, I have had to deal with 3500 convicts. Of these 245 were insane upon admission, 40 developed insanity during their incarceration, and 20 simulated insanity. Among the rest were to be found many who were feeble minded, epileptic, idiotic, or with imperfectly developed intelligence.

Many different forms of insanity prevail among convicts, the most usual being (1) delusions of attempts to introduce poison in their food; (2) delusions of bodily torture by electricity—this class rarely recover, and autopsies reveal decided cerebral lesions; (3) delusions of persecution and threatened bodily violence; (4) religious exaltation; (5) homicidal mania.

Many insane criminals have been criminals before they became insane: they are not criminals because of insanity, but independently of it, and they would be equally criminal if not insane.

Simulation of insanity is rarely met with by the general practitioner, since it is confined almost exclusively to prisons, the army, and the navy, where alone a motive for it exists.

It would be hard (if possible), to make the

general practitioner or specialist in nervous diseases believe how deceptively an ignorant, illiterate criminal can play the part of a lunatic. I have seen twenty cases in which the simulation would puzzle or deceive any physician. The efforts have lasted for days or months, and in many cases I could not have believed that the insanity was not real, had not the patient eventually confessed his simulation and abandoned it.

These subjects never claim to be insane. They usually first threaten suicide or make a safe pretense at attempting it. If this fails in securing for them what they desire, they soon claim as facts what is necessarily false. These false beliefs and delusions they persist in, often adding others of correlated character.

While some do such simulation badly, each does what he thinks will be most likely to make you believe him demented. A prolonged study of any one of them, will in time create a doubt as to its genuineness, to the unprejudiced observer. Insanity is sometimes produced by *continued* effort at simulating, which overtaxes the brain.

From my observations I would ask your attention to the following few cases:

Case 1—A convict began his masquerade about a month after reception by a claim of delusions and by violent outbreaks of violence and passion. After a few months he had reduced himself to a most disgusting and deplorable condition by his acts and filthy habits, in spite of constant efforts to keep him cleanly. He seemed to have arrived at the last stages of dementia, and a commission of our most prominent expert specialists in mental diseases, appointed by the court, declared him to be unquestionably insane. A month later, after an encounter with his keeper, in which he was for the first time punished, he asked to be put in another cell to work, and said his insanity was all a simulation, in the hope of removal to an asylum. From that hour he never showed the slightest indication of mental disease during the next six years.

Case 2—The Emma Bickel case need only be mentioned to demonstrate how easily a claim of insanity may be supported by medical testimony, although the subject is perfectly sane. Several murderers have recently been declared insane by experts; but when that failed in its purpose, and execution became inevitable, the last days of several of them were noted for entire absence of insanity or delusion, and full appreciation of their deeds, responsibility and impending punishment.

Case 3—An Englishman received as a convict a few months ago, soon after reception showed signs of delusional insanity, followed eventually by apparent apoplexy, very correctly simulated. Etherization, with a show of intended application of actual cautery, entirely and permanently cured the apoplexy and insanity as soon as the stage of ether intoxication had been reached.

Case 4—An intelligent farmer, guilty of murder, whose mental soundness was questioned, was not hung, but the grade of his crime was reduced to murder in the second degree. He was recently received to serve an eight-years' sentence in the penitentiary. On reception he was apparently in the last stages of dementia. Being convinced that it was not genuine, I assured him he would not be removed to an asylum, and advised him to give up his play, and behave like a man. A little rough usage by speech and a couple of shakings, in a few days convinced him that his attempt had failed, and he suddenly gave up the play, and has since been a perfectly sane, intelligent man.

Case 5—Dr. J. Wm. White, in one of the annual reports of the penitentiary, describes a case of a man who went on to the most loathsome and filthy practices of the badly demented, but who afterward acknowledged it all a masquerade, and ceased the pretence.

Case 6—The convict Taylor was not thought to be insane by any member of our profession, or the laity, whose study of him had been careful and continued over some months. His last days indicated his sanity, and he pleaded for pardon for the charges which he had made, and which he said he knew were false. The autopsy in his case revealed no brain lesion, but a brain characteristic of the low crime class.

Medical testimony has lost much of its proper influence over jurymen, probably caused by the bitter partisan position which experts permit themselves to take, imposing their varying opinions as positive facts on every one where opportunity offers.

Should the court conduct the mental investigation of prisoners, instead of either the prosecution or defense, it would do much toward elevating medical testimony to its proper place, and prevent its so degenerating in the estimation of the laity, as often to be successfully ridiculed.

—An Appendix to Neale's "Medical Digest," including the years 1882-3-4-5 and the early part of 1886, has just been published, and brings this valuable work as nearly as possible down to date.

BRONCHITIS FROM MECHANICAL IRRITATION.

BY T. C. SMITH, M. D., OF AURORA, IND.

The following case is of interest, as showing how easily we may sometimes be placed in error in diagnosis and treatment, and indicates how very serious consequences may result without our even suspecting the true exciting cause.

Bertha C., aged 5 years, is usually healthy and robust, though sometimes troubled with obstinate spasmodic cough resulting from cold and former tonsillitis. This, however, could be allayed by the active use of expectorants—chiefly bromides—or syrup ammon. iodid. She was brought to me the last week in February, 1887, with a very severe spasmodic cough that caused her mother to think she had an attack of pertussis. This I did not believe. Physical examination caused me to pronounce it a case of sub-acute bronchitis. There was slight febrile excitement, considerable "nervousness," pulse 110, cheeks flushed, increased respirations accompanied with considerable lifting of the shoulders at every inspiration, and a disposition to cough on expiration; there was no marked cyanosis. The respiratory sounds were loud, well marked and dry. The sibilant and sonorous râles were loud and distinct with both inspiration and expiration. The expectoration was white, tough, not very adhesive. A few times it was tinged with blood. The dyspnoea was considerable on exercise and at night on going to bed. The cough mixtures failed to give satisfactory relief, though they were persistently used, and as strongly anodyne, anti-spasmodic and expectorant as was safe to give. I should have mentioned before that resonance was fairly normal all over both lungs, being perhaps a little clearer on the right than left side.

A month of treatment availed nothing for real improvement. The faithful parents were becoming discouraged, and were apprehensive of chronic lung disease. Finally the child had an unusually severe spasm of coughing and threw out of her mouth a little brown triangular object, quite a half inch on each of its three sides, and very sharp at one point. Inspection proved it to be a piece of hazelnut shell that the child had drawn down the trachea a month before. Her mother distinctly remembered the time when the child seemed to choke a little and cough severely while eating these nuts, but as she soon ceased to be troubled for that

time, it did not occur to her that any part of the shell had gone into the bronchia. After its expulsion the cough ceased at once.

This case reminds me of one that was reported by—I believe—Dr. A. T. Keyt, to the Ohio State Med. Society, about 1872, where the case was diagnosed as tubercular phthisis, and was soon expected to die, when, all unexpectedly, a splinter of hard wood was expectorated and a fairly rapid recovery followed. I give this from memory, and believe I have stated it correctly, as then reported.

ACUTE MANIA CURED BY HEROIC TREATMENT.

BY H. V. SWERINGEN, A. M., M. D., FORT WAYNE, IND.

A young Irish woman. Married twelve or thirteen years. Has six children living. Had several abortions. Naturally anæmic. Ambitious and industrious. Has done all her own work except during periods of confinement.

I have given her, with decided benefit, the usual remedies prescribed for anæmia, chlorosis, leucocythemia, neurasthenia, etc., etc. But as soon as she felt better they were discontinued until a relapse would occur, when, after bearing it as long as she could, she would again apply for medical aid, and so on *ad infinitum*.

About nine or ten weeks after the birth of her last babe which now (June 21) is about three months old, she had one night a very peculiar mental attack, which aroused her household and neighbors.

She labored under the delusion that her husband, a locomotive engineer then out on his run, was killed. In spite of the assurances of her friends to the contrary, she would not be comforted, but screamed, lamented and cried at a furious rate, until a short time before my visit on the following morning, when she seemed to recover her usual composure, but it was quite plain that something was radically wrong with her mind.

While she answered my questions rationally enough, she was in what is called a "nervous" state, with an anxious, unnatural expression of face.

In answer to the usual questions from friends, I told them that her condition was due, in my opinion, to the fact that she did not have blood enough in her body to nourish her brain, and that as a result, it had lost its equilibrium, the cerebral cells having be-

come irritated, disconnected, their continuity interrupted, etc., etc., or words to that effect.

The idea of puerperal mania, or insanity, suggested itself; but I could find nothing in the case to support it other than the facts above given.

I requested the friends, however, to watch her very closely day and night, telling them she would be apt to kill her babe, throw herself in the cistern or river, or enact some other fearful tragedy.

She passed the day fairly well, but in the night again became delirious or maniacal, requiring restraint, the attendants being obliged to hold her in bed, from which she would occasionally start or rise up suddenly seeing something horrible to look at: a fire burning up a family, or a child drowning, or sights of this nature.

I considered the bromides contraindicated in the case, for reasons which are at once apparent to the reader, and endeavored to control her excessive, obstinate wakefulness by food, stimulants and tonics. But she became wholly indifferent to the entreaties of her friends, and refused to eat or drink any and all preparations offered to her.

I gave her various hypnotics, sedatives, nervines, foods, digestants, etc., which her husband, who seemed to have the most control of her, occasionally succeeded in coaxing her to swallow, but without any appreciable effect. I obtained the best results from the hypodermic injection of a third of a grain of morphine; but unfortunately they were only temporary. I tried to get some hyoscyamine, intending to use it in the same manner to the extent of one hundredth grain; but there was none to be had in the city, I am ashamed to say. I telegraphed to Chicago for it, but even in that great City of the West I failed to obtain it.

I remember to have used it successfully in a very aggravated case of chorea in a young married woman in a distant town where the attending physician, satisfied with having administered the prescribed remedies in the prescribed doses without effect, folded his arms and looked on as a mere passive spectator, leaving the case entirely to nature.

In the meantime my patient became exceedingly noisy and violent, having broken the sash of the window at the foot of her bed. Prior to this she was comparatively quiet; indeed at times she was unusually so. This, as we subsequently learned was for a purpose, illustrating the peculiar cunning of the acutely insane. She at times *pretended* to be asleep and when she thought her attendants

were dozing she made sly efforts to leave her bed and room. Occasionally she caught a word spoken by one of the nurses, when she immediately began to repeat it rapidly, even singing it at times, ever and anon breaking out in a familiar tune.

It had now come to be a desperate case. Her husband gave her up as hopelessly insane, and the friends began discussing the propriety of sending her to the State Asylum. It was time *something* was done, and done quickly. I was yet hopeful that if I could put her to *sleep*, and keep her asleep *continuously* for 24, 48 or 72 hours, she would awaken very much improved if not entirely rational.

I would then be satisfied at least that I had done my whole duty, or that a prolonged sleep would avail nothing. We were now entering into the 4th or 5th night, and the question was *how* to get her asleep. Two attendants were holding her in bed while she was alternately screaming, singing and making violent efforts to get away.

Now comes the most interesting, important and instructive part of the case, viz: its therapeutics, the effect of which, although not wholly unexpected, was surprisingly successful.

I had a desperate case before me, and resolved upon a corresponding course of treatment. Had my patient died, it is questionable if I should have reported the excessive dose I gave her; but she lived, and immediately improved, after the artificial sleep induced by nearly a whole grain of morphine injected into her arm, followed at once by chloroform inhalations. She slept until morning, when she awakened perfectly rational, took some nourishment and again went to sleep.

She thus slept and wakened for several days and nights, occasionally talking "a little off," as her husband expressed it; but on the whole constantly improving, although she remained very weak. I am quite certain she could have taken double the dose given, without serious toxic effects, in the condition she was in when I gave it to her.

It has been my experience in these cases that *small* doses only aggravate the condition we seek to control, and a tolerance for very large doses is established by the very nature of the case.

There are physicians who would no more exceed the dose recommended in the books, than they would cut off their own fingers.

It is right that we should have some standard, some rule of guidance, and some safe limit in posology; and the physician has

no business, perhaps, to violate on his own responsibility in a case of this kind such a limit in using toxic remedies. But one large, heroic, positive dose is worth a million small ones, which serve only to increase the trouble we are trying to relieve. There is much to learn yet in what may be called exceptional posology in exceptional cases. Circumstances alter cases; I believe it was the *size* of the dose that cured my patient.

REPORTS OF SOCIETIES.

THE SIXTEENTH CONGRESS OF GERMAN SURGEONS.

[Continued from p. 780.]

Sterilized Dressings.

DR. SCHLANGE, of Berlin, thinks that to insure an absolutely aseptic condition of the various materials for dressing wounds, it is best to sterilize them by exposure to a jet of steam at a temperature of at least 100° C. (212° F.)

PROF. VON VOLKMANN, of Halle, does not see any necessity for such procedure. It is well-known that bacteria will colonize under the best antiseptic dressings, and it is impossible to kill every single coccus. The human body is not a test-tube, but it has a certain power of resistance against cocci, and therefore it is sufficient if the surgeon has *clean hands*, uses *clean instruments*, and sees that the wound and its surroundings are *thoroughly disinfected*. On this iodoform-gauze is packed, and covered with moss or some other *desiccating* material. No tissue impermeable to fluids, such as rubber-tissue or mackintosh, should be interposed, for these favor the development of micro-organisms. Dry dressings will promote healing with absolute certainty by reducing the number of bacteria and the poisonous ptomaines produced by them.

PROF. VON BERGMANN, of Berlin, prefers to use sterilized dressings because they protect the wound from microbes, which give rise to infection by direct migration, e.g. erysipelas.

VOLKMANN mentioned the fact that among other cases, he has treated more than 300 cases of compound fracture without any death or any case of erysipelas.

BERGMANN thinks that this is no proof that such infection is *impossible*.

DR. LÖFFLER, of the Imperial Sanitary Board at Berlin, has found that the material used for antiseptic dressings—stored away in great masses for an emergency by the direction of the army officials—is as good as ab-

solutely sterilized if the middle of the packages is taken as a test. Only the most external layers of these compressed packages occasionally contains a few germs capable of being developed.

Value of Iodoform as an Antiseptic.

DR. DE RUYTER, of Berlin, has made some experiments in conjunction with Dr. Bearing to disprove the attacks made by Drs. Heyn and Rovsing, of Copenhagen, on the utility of iodoform as a dressing for wounds. He admits every thing that has been alleged as far as iodoform, as a *dry powder*, is concerned; but he has shown that in the secretion of wounds the drug is always decomposed, and a certain chemical combination is formed between iodine and albuminoids in the secretion, and especially the ptomaines produced by bacteria. In sterilized blood iodoform remains unchanged.

That the decomposition of iodoform is produced by the ptomaines, which in turn are rendered innocuous by the chemical combination thus engendered, is apparently paradoxical; yet, the incomparably beneficial and unprecedentedly reliable action of iodoform is without doubt due to this peculiar property, that it is only a tative when decomposed by the secretions of the human body.

It must be remembered that solutions of the element (iodine) itself in similar proportions have not been found to act as well as solutions of iodoform of the same strength. The best action is secured by a solution of iodoform, in alcohol and ether, which is the most rapid means to sterilize dressings.

In the discussion: PROF. VON VOLKMANN stated that he felt glad to see iodoform vindicated. The results published by the Copenhagen investigators were so diametrically opposed to all surgical experience that such vindication was sure to come, and he was glad it had come.

DR. SANGER, of Magdeburg, corroborated the findings of Drs. De Ruyter and Behring by relating his experience, showing that even the poison of anthrax is destroyed by continued action of iodoform on the pathogenic bacillus. In his opinion it is the decomposition of the iodoform, which favors this germicide action. In wounds, primarily made aseptic, iodoform does all that is claimed for it.

PROF. BRUNS, of Tübingen, reported the favorable results he has obtained by injecting iodoform solution (10 per cent. in glycerin and alcohol) into all kinds of cold (tuberculous) abscesses. He has found that of 54 patients 40 were cured and the microscopical

examination of the walls of the abscesses by Prof. Nauwerk showed that the tubercles are arrested in their growth, the bacilli disappear, and the infectious walls of the abscess necrose, or undergo fatty degeneration, by the establishment of normal vascular granulations. The action of iodoform Prof. Bruns therefore designates as *specific and antibacterial*.

Transplantation of Skin.

DR. WAGNER, of Koenigshuette, illustrated the covering of defects on the arms by using portions from the skin over the thorax, by a case of extensive burns on the arm and forearm of a patient. He gives the rules laid down by the late Prof. Maas:

1. The thorax and arm must be immobilized with plaster of Paris dressing.
2. The superficial granulations on the part to be covered must be pretty deeply removed.
3. The flap to be used must be dissected off, following closely the distribution of the vessels, even if a decided turn has to be given to the base of the flap.
4. The flap must be stitched very accurately to the margin of the defect, and it may be approximated closely to the granulating surface by a few deep sutures.
5. A thick layer of boracic acid ointment ought to protect the exposed portions of the flap from becoming necrotic through desiccation.

6. The base of the flap ought to be divided in from ten to fourteen days.

He presented some patients on whom he operated in accordance with these rules with excellent result.

One of these was a laborer who had had the skin taken almost entirely off from his right arm. Two transplantations were made, first from the right and then from the left side of the thorax; the first about four months after the injury, the second about six months later. The result was very gratifying. Sensibility was acquired in the arm almost fully; but even mobility was restored to a limited extent, although there had been a fearful loss of muscle substance. His experience in this and similar cases leads him to consider careful suturing of the flap to the margins of the wound unnecessary, close apposition to the granulating surface being much more important.

WAGNER thinks that this method of transplanting skin is a great achievement in plastic surgery, and points to various conditions heretofore deemed almost incurable, such as large old ulcers of the leg, etc.

Prof. HELFERICH, of Greiswald, reported a case similar to those of Wagner; he has,

however, followed the advice of Prof. Thiersch, and studded the fresh granulating surface with small pieces of epidermis.

One point of importance is to protect the base of the flap from pressure which might endanger circulation.

Dr. HANS SCHMID, of Stettin, advises an early operation in these cases, especially when joints are implicated, as he has had a case in point. It is the best means to insure the greatest possible mobility of the limb.

Uranoplasty and Staphylorrhaphy in Early Infancy

was advocated by Prof. WOLFF, of Berlin. He has operated during the last two years on 24 cases of cleft-palate, 14 of the patients being below five years of age. In a very few cases only a second operation was necessary, and the condition of his little patients was invariably excellent, and remained so throughout the whole treatment. These favorable results Wolff ascribes to his methodical practice of using wound compression; and, in the after treatment, copious irrigations of the parts while the patient's head is hanging down over the end of the table.

In addition, in the majority of his cases he never made use of an obturator, and then only for a time. The speech in almost all the cases is very distinct, and has a normal and agreeable *timbre*, nearly all the nasal twang disappearing. He was able to present a half dozen of his patients, the youngest being 15 months, the oldest 8 years old. The earlier the surgeon ventures to operate, the better are the results, especially as to speech.

[To be concluded.]

Treatment of Syphilis.

In the discussion of the general treatment of syphilis by the Paris *Société Médicale des Hôpitaux*, M. Martineau gave a resumé of his practice, as follows: "This virulent constitutional affection should be treated in three ways: 1, with Mercury; 2, with Iodine; 3, with Sulphur. As regards the mercurial treatment, M. Martineau greatly preferred the cutaneous, and particularly the hypodermic method of its introduction. He employed a mercuric ammoniacal peptone (formula of Delpech) containing ten milligrammes of the sublimate. M. Martineau has made not less than 180,000 injections since 1881. There is nothing whatever objectionable in the method employed; the action is quick and most efficacious. The injections are made in the

back and may be given every two or three days. After a month of this treatment M. Martineau, for another month, gives by the stomach, daily, a teaspoonful of ammoniacal peptone (equivalent to five milligrammes of the sublimate). This method has great advantages over that of the injection of insoluble salts. The explanation of the method of the use of sulphur was deferred until the next meeting."

Cremation by the Bourry System.

The cremation society at Zurich, Switzerland, one of the best organized associations in the world, has adopted the Bourry system, which is described as follows: "Like Siemens, Mr. Bourry allows only heated air to communicate with the body. In both systems the corpse burns directly; no flame is to be seen singeing the body, but it burns itself by the abundance of hot oxygen which surrounds it. Bourry uses carbonic acid gas, prepared in a coke regenerator, for heating the crematorium. During the process of cremation he uses mainly chimney gases for heating the air before it touches the corpse, which allows a more economical use of the heat. It is of great advantage that the chimney should be thirty-five feet high from the base of the cellar, so that it is fully covered up by the building. The ashes fall, without being touched, by an almost automatically working apparatus, into the urn. The dissolution of the body does not take place in the dark, unseen and uncontrolled, but the whole action is clear and open. Bourry and Venini place the crematorium, which has the shape of a sarcophagus, and which can be approached from all sides, in the midst of the hall in which the service is to take place. There is a little window on the back of the sarcophagus through which one can see the process of cremation, which is completed within one to one and one-half hours, without smell or smoke. The process is solemn and beautiful, and avoids every unæsthetic manipulation."—*The Sanitary News*, May 14, 1887.

—Prof. Tumas points out in *Tratch* that calomel has an antiseptic action on bile. He finds that bile, when mixed with calomel, will remain unchanged for several days at 59° F.; while a specimen unmixed with calomel became rapidly putrid and turned to a reddish color.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Treatment of Epistaxis by Counter-Irritation Over the Hepatic Region.

In a letter to the *London Lancet*, Alexander Harkin, M.D., F.R.C.S., thus emphasizes the value of counter-irritation in epistaxis:

I was much pleased to observe in a letter from your Paris correspondent, dated April 27th, that at a recent meeting of the Academy of Medicine M. Verneuil read a communication upon the treatment of certain forms of epistaxis by counter-irritation over the region of the liver. In the first case related by M. Verneuil, quinine, ergotine, and digitalis had all been tried in vain. In the second, plugging had failed. The third had been the subject of chronic nephritis, with secondary affections of the heart and liver, and the cavity of the nose had been plugged without effect both with ergotine and the perchloride of iron. M. Verneuil's treatment, which was immediately and permanently effective, consisted in the application over the region of the liver of a large blister. M. Verneuil had at first thought that the method was entirely his own, but from bibliographical research it turned out that it had been anticipated to a certain extent by Galen, who says that large cupping glasses applied to the hypochondriac region arrest nasal hæmorrhage. To me it is very satisfactory to learn that a mode of treatment practised by myself successfully for many years, and reported in *The Lancet* of Oct. 30th, 1886, with cases in illustration, has also been advocated by so eminent an authority in Continental medicine, and as far as he was concerned, independently of any suggestion from another. I am quite sure that, in his case any more than my own, the dictum of Galen had nothing to do with its origination. It is of more importance that the remedy, which is undoubtedly of the utmost value, should be more generally adopted, especially when its application is urged not upon merely empirical grounds, but in accordance with accepted pathological teaching. That your correspondent did not appear to be aware of my previous pronouncement on the subject arose possibly from the fact that my publication did not take the form of a monograph with specific heading, but as a portion of a paper treating of congestion of the liver, and protesting against the impolitic interference

of modern surgery with the sanitary efforts of Nature when through the medium of hæmorrhage from the hæmorrhoidal veins or the mucous lining of the nostrils she endeavors to lessen the turgescence of an important viscus. In illustration of my views, I gave the particulars of a case of vicarious bleeding from the under lip, which arose immediately after the de-ligation of hæmorrhoidal tumors with excessive bleeding, ultimately cured by blistering over the liver; of a second example, in which dangerous and profuse hæmorrhage from piles was immediately cured by a similar remedy; and then, in pursuance of my theme, appended the cases of three young men suffering from epistaxis, who were instantly relieved by blistering over the hepatic region. A remarkable case, which occurred during the recent riots in Belfast will further illustrate the subject: While paying my morning visit to a straw lodge, temporary barracks improvised for the members of the Royal Irish Constabulary, and accompanied by one of the officers, I found one of the men in bed with a handkerchief saturated with blood, which had flowed from his nose during the greater part of the previous night. On satisfying myself of the nature of the illness, I painted the man freely with the liquor epispasticus over the region of the liver, prescribing no other remedy but rest in bed. On our revisiting the man next day, he informed us that from the moment the blister began to pain him the hæmorrhage declined, and left him altogether a short time after. To quote from my paper: "The frequent occurrence of epistaxis in youth is evidently due to the excitement and hyperæmic condition of the liver and digestive organs during the period of active growth and the constant demands upon its functional activity. The liver at this stage closely approximates to the condition in after-life, which is the causal factor in the development of piles, and as such is equally amenable to treatment in accordance with etiological principles; the derivative that cures the hæmorrhoidal flux as certainly puts an end to the epistaxis, the outcome of hepatic congestion."

Influence of Infused Beverages on Digestion.

Dr. James W. Fraser has studied experimentally the action of our common beverages on gastric and intestinal digestion. These are his conclusions:—(1) It is better not to eat most albuminoid food-stuffs at the

same time as infused beverages are taken, for it has been shown that their digestion will in most cases be retarded, though there are possibly exceptions. Absorption may be rendered more rapid, but there is a loss of nutritive substance. On the other hand, the digestion of starchy food appears to be assisted by tea and coffee; and gluten, the albuminoid of flour, is the principle least retarded in digestion by tea, and it only comes third with cocoa, while coffee has a much greater retarding action on it. From this it appears that bread is the natural accompaniment of tea and cocoa when used as the beverages at a meal. Perhaps the action of coffee is the reason why it is usually drunk alone or at breakfast—a meal which consists much of meat, and of meats (eggs and salt meats) which are not much retarded in digestion by coffee. (2) Eggs are the best form of animal food to be taken along with infused beverages. Apparently they are best lightly-boiled if tea, hard-boiled if coffee or cocoa, is the beverage. (3) The caseine of the milk and cream taken with the beverages is probably absorbed in a large degree from the stomach. (4) The butter used with bread undergoes digestion more slowly in presence of tea, but more quickly in presence of coffee or cocoa; that is, if the fats of butter are influenced in a similar way to oleine. (5) The use of coffee or cocoa as excipients for cod-liver oil, etc., appears not only to depend on their pronounced tastes, but also on their action in assisting the digestion of fats.—*Journal of Anat. and Physiol.*

Nasal Vertigo.

The following conclusions are drawn from an interesting work by Dr. Joal (du Mont Doré):

I. There exists a nasal vertigo, true vertigo, *a naso laeso*.

II. It belongs to the group of reflex vertigoes, and should be classed with gastric, laryngeal, and uterine vertigo.

III. Irritation of the branches of the trigeminal innervating the mucous membrane of the turbinated bones and of the septum is the cause of vertigo and of other nasal neuroses.

IV. Irritation of the trigeminal passes through the medium of the sphenopalatine ganglion to the vaso-motor nerves, whence comes circumscribed anemia of the brain, with vertigo.

V. Vertigo is induced by the following causes: 1st. Nasal inflammation (due to odors, irritating vapors, snuff, and grasses, when flowering); 2d. Acute coryza; 3d.

Chronic catarrh, especially in its hypertrophic form; 4th. Polypi of the mucous membrane; 5th. Catarrh of the posterior nasal cavity.

VI. Vertigo is induced chiefly by nasal affections of apparently slight consequence.

VII. Nasal reflexes are most common with gouty subjects.

VIII. Vertigo may show itself alone or accompanied by other nervous phenomena: visual trouble, *muscae volitantes*, hemicrania, nausea, vomiting, nervous excitability, hypochondria, sluggishness of intellect, nightmare, spasmodic cough, dyspnoea, increased secretions, syncope, weak pulse, and pallor of the face.

IX. To form a diagnosis, it is necessary to examine the nasal fossa of the person suffering from vertigo.

X. Investigation of nasal vertigo will diminish the number of cases attributed to gout, rheumatism, anemia, congestion, as well as to cerebro-cardiac neuropathy.

XI. The vertigo will cease when the nasal affection to which it is due has been cured.

Santonate of Atropine.

The difficulty that is experienced in preserving solutions of atropine, owing to the formation of mucors which are highly objectionable in ophthalmic practice, has led M. Bourbelon to endeavor to obtain a stable compound. He believes he has accomplished this end in the employment of santonate of atropine, the solution of which produces no irritation when applied to the eye, whilst its power of dilating the pupil is the same as that of atropine sulphate. One drop of solution of atropine santonate containing 1 part in 2,000 of water dilates the pupil in six minutes, and the action is maintained for a period varying from ten to twenty-four hours. Atropine santonate has not been hitherto obtained in a crystalline state. It appears in the form of a white powder which has no hygroscopic properties. It is requisite to observe that the santonate and its solutions ought to be preserved in flasks of yellow glass, in order to avoid the action of light and the formation of photosantonate acid. It may be borne in mind that a valuable suggestion was made some years ago by Dr. Aquila Smith for the preservation without deterioration of solutions of atropine, which consisted in using as a menstruum the camphor water of the Pharmacopœia; the only objection to which is that it causes slight smarting when first introduced into the eye. This, however, soon passes off, and has not been attended, in any case hitherto observed, with troublesome consequences.

Innominate Aneurism—Ligation of Common Carotid and Sub-clavian Arteries

—Recovery.

At a recent meeting of the College of Physicians of Philadelphia, D. H. R. Wharton reported a case of aneurism of the innominate artery, cured by distal ligation of the carotid and sub-clavian arteries. The patient was a man 42 years old, who came under Prof. Pepper's care, in the Hospital of the University of Pennsylvania, in November, 1886. After the diagnosis was established he was transferred from the medical to the surgical ward, and came under the care of Prof. Ashhurst. On Nov. 13, he was operated upon by Prof. Ashhurst, who cut down upon and ligated the right common carotid artery, just above the omohyoid muscle, with a stong cat-gut ligature. The right sub-clavian artery was next exposed and ligated in its third part, just outside the anterior scalenus muscle, with similar material. The wounds were closed with silver sutures, drainage tubes being introduced, and the wounds dressed with oiled lint. The whole right arm was wrapped in cotton, to maintain its temperature. There were no symptoms of disturbance of the cerebral circulation by the cutting off of the supply of blood from the right carotid artery. In a few days the aneurismal tumor was smaller and firmer, and its pulsations less forcible. The dysphagia and dyspnoea, of which the patient had complained, were also very much lessened. On January 13, 1887, two months after the operation, the patient was dismissed from the hospital.

Dr. Wharton reported that he had found the records of thirty-two cases of simultaneous double distal ligation of the right carotid and subclavian arteries for innominate aneurism, followed by recovery in twelve cases, death in sixteen cases, and temporary improvement in four cases.

The case reported, and operated on by Prof. Ashhurst, is one of the most brilliant of these cases, and fortifies the opinion expressed by him, that the method of simultaneous double distal ligation is preferable to the operation on one vessel at a time. In speaking of the manner of performing the operation, Prof. Ashhurst, and others who spoke after him, dwelt upon the importance of exposing as little of an artery as possible in ligating it.

The patient was shown at the meeting in a condition which was a remarkable contrast to that in which he was, immediately before he was operated upon.

The Uses of Sulphate of Sparteine in Cases of Morphine Habit.

M. Ball and Dr. Oscar Jennings, after considerable experience in severe cases, have found the best course of treatment for tiding over the difficulties of the time of the compulsory abandonment of the morphine is by hypodermic injection of sulphate of sparteine in doses of from one-sixth to one-third of a grain. This acts as an immediate cardiac stimulant. They do not find sudden and complete suppression of the use of morphine in such cases always advisable, but give some occasionally in dangerous collapse. They testify also to the usefulness of a few drops of a solution of nitro-glycerine put on the tongue as giving momentary relief in moments of crisis.—*The Practitioner*, June, 1887.

Treatment of Ophthalmic Headache.

Giles de la Tourette and P. Bloch, pupils of M. Charcot, have recently made known the views of their eminent master on this subject. Féré has already described the different forms which ophthalmic headache may assume. It differs clearly from other headaches by many symptoms which may be styled specific. Mr. Charcot admits of two varieties of ophthalmic headache—the one, simple, consists solely of pains in the head and visual disturbance; the other, "headache with complication," presents, in addition to the former symptoms, a transitory aphasia, more or less pronounced trouble of the sensory and motor nerves of the limbs and side of the face. In simple ophthalmic headache with transient amblyopia under the form of hemiopia and scintillant scotoma, the prognosis is favorable; the affection is annoying but not alarming. It is far different in the compound form; when aphasia supervenes, when the patient experiences formication on one side of the body and symptoms of paresis and even epileptiform attacks both he and those around him may well feel alarmed. If the crises are frequent he may be obliged to give up his occupation. Finally, it has even been found that each of the above cited symptoms—hemiopia, aphasia, sensory and motor disturbances—after having shown themselves ephemerally, may increase in duration or become chronic. It is therefore of service to learn that Charcot had obtained marked success by a bromide treatment applied in the following manner: The patient should be powerfully, continuously and for a long time, impressed. These important indications may be fulfilled

as follows: The patient is given 30 to 45 grains of bromide each day of the first week, 45 to 60 grains of bromide each day of the second week, 60 to 75 grains of bromide each day of the third week, 75 to 90 grains of bromide each day of the fourth week, and then re-commence the same series. According to the mitigation or otherwise of the attacks, diminish or augment in like ratio the doses; but the treatment should not be suspended before a complete and permanent cessation of all the phenomena occurs. The minimum duration of this treatment will never be less than three or four months.

Bisulphide of Carbon in Pulmonary Disease.

Wallace A. Briggs, M. D., writes as follows to the *Sacramento Medical Times*, July, 1887:

Carbon bisulphide, whose virtues in enteric fermentation Dujardin-Beaumetz has so highly extolled, has more recently come into extensive use in the treatment of chronic pulmonary troubles. It is not my purpose here to discuss the value of the remedy as much as to call attention to a simple and, I believe, efficacious method of its administration, viz.: that of Dujardin-Beaumetz in gastro-intestinal fermentation already referred to. In this way I have employed it for several weeks, and seemingly with all the advantages to be derived from gaseous rectal injections, which are certainly more troublesome to the physician and more repugnant to the patient. The formula I use is ordinarily the following:

R. Carbon bisulph. pur.....50 gms.
Aqueæ menth. piper.....2000 c. c.
M. ¹

This is to be thoroughly shaken and, after settling, is ready for use. Only a small part of the bisulphide will dissolve, and the bottle may be frequently replenished by filling it with mint, gaultheria, or whatever aromatic water is preferred, and thoroughly shaking and settling as at first. The dose is from two to six ounces, with an equal quantity of water or milk, four or five times a day. In one case of chronic bronchitis with bronchiectasis, a very marked improvement in cough, expectoration, and strength has been coincident with the use of this solution. Other cases of chronic pulmonary trouble, including one of chronic, or perhaps subacute, broncho-pneumonia, have seemingly been favorably influenced.

¹ [For all practical purposes this mixture is in the strength of one fluid ounce of bisulphide to the quart. Bisulphide of carbon, when freshly made and pure, is much less unpleasant than that ordinarily obtained. —EDS. REPORTER.]

Treatment of Whooping-Cough.

Cadet de Grassicourt states, that according to his experiments, grindelia robusta is not a specific in whooping-cough. Exhibited as an etherial extract in doses of 20 to 50 drops a day, it may, in certain cases, diminish the number of paroxysms, and can be employed when other means have failed. M. Bilhaut had reported more satisfactory results but one must take into account in this species of inquiry differing circumstances which investigators too often neglect; such as whether the attack is mild or severe, and if the disease is in its early or more advanced stage. Syrup of narceia, recently advised by Labarde, painting the posterior fauces with cocaine, bromide of potassium, and breathing compressed air, are to be remembered as having been successfully employed. The advantages of change of residence in the decline of whooping-cough are conceded by everybody, and frequent change of rooms simply is often attended with good results. In this case it is advisable that the chambers of the invalid should each time be disinfected with sulphurous fumes. M. de Grassicourt does not think it advisable to permit whooping-cough patients to go out often at the acute period, particularly when less than three years old, for fear of broncho-pneumonia. How long whooping-cough is contagious is not decided; it is likely that contagion is possible so long as the paroxysms are clearly marked. The assertion of an authority in infantile pathology that whooping-cough is not contagious after the second month, when the cough persists, is debatable. It is probable that transmissibility ceases when the paroxysms are short and supervene at distant periods. But it is impossible to fix the precise date.

Napelline in Facial Neuralgia.

In a paper on napelline in facial neuralgia, M. Grognot adduces the following case by way of illustration. He states that he was called to see a young girl suffering from severe pain extending over the entire head, which felt, she said, "as if it were pressed in a vise." The pain, however, was greatest on the right side in the parietal and frontal regions, and immediately above and below the eye it attained its maximum intensity. There were no tears, but, according to the patient, there had been in previous attacks. The tongue was slightly coated, but there were no caries of the teeth on the side affected. The author prescribed one granule, containing $\frac{1}{2}$ grain of napelline, every two hours. On the first day the pa-

tient took ten granules; during the evening the pain disappeared. Although the pain had not returned the next morning, the patient was advised to take four granules and two the following day. Two months later the patient's neuralgia re-appeared, and she took eight granules. The next day he found the neuralgia had disappeared, and since that time the health of the patient has been excellent.

Napelline is an alkaloid, obtained from the aconitum napellus. An account of its chemistry appears in the *Pharmaceutical Journal* for 1872, p. 245. It is mentioned in the Supplement to Neale's "Digest." It is said to occur as an impurity in amorphous aconitum.

Tubercular Laryngitis.

M. Hering, of Warsaw, records twenty-nine cases of laryngeal tuberculosis treated by scraping. He divides these cases into three groups. 1st. Nine cases of tubercle in which after one year and three months the cicatrix remained healthy. 2nd. Nine cases of recurring tubercle, again treated by scraping, with three cures. 3rd. Six cases of ulceration of the nose, pharynx, and tongue. The general health was bad. In two cases there was partial cicatrization until the time of death.

REVIEWS AND BOOK NOTICES.

[Those sending Books for Review will oblige our readers by always stating publication price. In the case of Reprints, authors are requested to state the conditions upon which copies may be obtained by those of our readers interested in the subjects treated.]

NOTES ON CURRENT LITERATURE.

—The first edition of Mr. Christopher Heath's well-known "Dictionary of Surgery" has been exhausted, and a new edition is shortly to be issued.

—Dr. G. E. De Schweinitz, of Philadelphia, sends us a very interesting Series of Cases, illustrating various forms of hemianopsia and other irregularities of the field of vision. It is reprinted from the *Journal of Nervous and Mental Diseases*, May, 1887.

—"The Uses of Adhesive Plaster in Orthopædic Surgery" is discussed in a very clear and practical way by A. B. Judson, M. D., of New York. The pamphlet before us is reprinted from *The New York Medical Journal* of June 4, 1887.

—It is pleasing to our national pride to note that the only important German Dental

Journal (*The Journal für Zahnheilkunde*), is one published by a society of doctors of dentalscience who were graduated in America.

—A semi-romantic interest attaches to the medical activities of the Orient, and we are glad to welcome a new journal from Constantinople, *The Hospital Gazette of the Ottoman Empire*. The June number informs us that Zoëros Pacha has instituted a laboratory for antirabic inoculations, and is about to apply the method in the case of a boy aged fourteen.

BOOK NOTICES.

Practical Urine Testing. A Guide to Office and Bed-side Urine Analysis. By Charles Godwin Jennings, M. D., Professor of Chemistry and Diseases of Children, Detroit College of Medicine, etc. 16mo, pp. 124.

This is a handy volume, containing a brief statement of the constituents of normal urine and the substances found in disease of the genito-urinary apparatus, together with the various processes for qualitative and quantitative analysis. A number of cuts illustrate the sedimentary deposits which are found in the urine. Altogether, the book will prove helpful to those to whom it is addressed.

Transactions of the Texas State Med. Association. Annual Report of the Special Committee on Surgery, 1886. Compiled and edited by George Cupples, M.D., etc. Quarto, pp. 26.

This interesting report contains elaborate tables of the surgical work done in Texas during the year 1886. It was prepared after distributing 3,000 circulars asking for statistics throughout the State, to which sixty-six surgeons replied. The resulting report is creditable to the zeal and enterprise of the committee and to the skill of the surgeons of Texas.

The Diagnosis and Treatment of Hemorrhoids, etc. By Chas. B. Kelsey, M. D., Surgeon to St. Paul's Infirmary for Diseases of the Rectum, etc. 16mo, pp. 78. Detroit: George S. Davis, 1887. (The Physicians' Leisure Library, No. 1.)

This little paper-covered book is the first of a series of twelve small monographs, which are being published by Mr. George S. Davis, at the rate of \$2.50 a year, or twenty-five cents for a single number. If for this price the purchasers always get as valuable a production as that by Dr. Kelsey, we think they may be congratulated.

THE Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record, -	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The edition for this week is 5,000 copies.

TRUE CIRRHOSIS OF THE LIVER, VS. CARDIAC CIRRHOSIS.

The following points with reference to the so-called "nutmeg liver," now seem agreed upon by histologists.

It is the mottled appearance of the liver in certain stages of cardiac cirrhosis which gives it the name of nutmeg liver; the color is due to the mode of distribution of the blood.

At the onset of the lesion the hepatic gland presents nothing abnormal. At an advanced period the tissue becomes firmer and denser, the parenchyma is bogged with blood, and the blood-stasis continuing, the hepatic veins swell even to their capillaries. If at this period you take a section of the liver you see the nutmeg appearance above alluded to; there are dark spots corresponding to the dilated intra-lobular veins, and relatively clear spots corresponding to the compressed peri and interlobular veins, and green spots due to biliary stasis.

The hepatic tissue is more resistant than natural, but the lesions are not yet great, and the cells are still centres of an active nutrition. Soon, however, these cells are choked out by the distended veins and capillary net-work, and the atrophy, giving place to connective tissue and granules.

As the disease progresses, the connective

tissue contracts, and the liver diminishes in volume (atrophic stage of the nutmeg liver); then the organ takes a granular aspect. It is at this point of the disease that it is apt to be confounded with true cirrhosis. Cardiac cirrhosis, however, is a sort of soft atrophy, while true cirrhosis is a hard atrophy; in fact the cardiac liver never attains the consistency and firmness of true sclerosis. In the latter disease, moreover, the vascular distention begins with the periphery; while in the former it is the central venous radicles which are first affected, and the peripheral are involved only secondarily.

Cardiac cirrhosis at the onset consists of a circulatory trouble without lesion. Sclerosis is characterized by a development of connective tissue, which thickens and proliferates, forms adhesions, and contracts more in some places than in others, and gives a peculiar lobulated appearance to the liver. On section the liver is hard, sometimes even lardaceous, and creaks under the knife. There are numerous salient granulations between the thickened prolongation of Glisson's capsule; the tissue has a tawny yellow color; sometimes the section is clear and shiny.

The hepatic cells, normal in certain points, are destroyed or fatty in others. Little by little, owing to retraction of the cellular tissue, the glandular parachyma is choked out and destroyed.

HEROIC TREATMENT.

In this number we publish an interesting report of a case of acute mania, which was cured by the combined use of a hypodermic injection of morphia and chloroform inhalations. This is practically the method of "mixed narcosis," recommended some years ago by Prof. Nussbaum, for producing anesthesia in surgical operations. Nussbaum injected a quarter of a grain of morphia, about fifteen minutes before beginning the inhalation of chloroform. In this way he secured a quiet and prolonged narcosis with the use of a comparatively small quantity of the chloroform. The effect of the morphia was two-fold: it acted as a heart-tonic, counteracting the depressing influence of the chloroform; and it prolonged the state of insensibility which the chloroform produced. The method has not secured universal adoption; but it is one of great value in tedious surgical operations, especially when chloroform is used instead of ether. It is also a very useful method to be employed in acute mania, or tetanus with convulsions, or in those cases of ideo-motor excitability which are often mistaken for hydrophobia.

NEW TEST FOR WATERED MILK.

Szilasi, according to the *Lancet*, of June 11, has recently proposed a new test for pump-water in milk. It is based on the fact that sulphate of diphenylamine is colored blue by the action of an exceedingly dilute solution of a nitrate. As well water always contains more or less nitrates, its presence in milk can be detected. The test is thus carried out: Twenty minims of sulphate of diphenylamine is placed in a small porcelain vessel, and a few drops of the milk to be examined are added to it. If the milk contain even 5 per cent. of average well water a blue tinge will gradually distinctly appear. Sulphate of diphenylamine is very cheap, so the test may be readily tried.

ENGLISH DOCTORS DISAPPOINTED.

The profession in Great Britain is a trifle hurt at what it considers a slight in the relatively few titles conferred upon medical men at the Royal jubilee. No baronets at all were chosen from the medical ranks, and only three knighthoods were conferred. This may all be very well, and not really unimportant, but we think that the physicians of America are to be congratulated in that they are removed from the temptation of aspiring for tinsel. *The Medical Press and Circular* of June 29, 1887, says: "To us it seems rather a poor reward for a life largely spent in ministering to the sufferings of a gouty aristocracy to receive only a knighthood, and we are almost betrayed into a hope that some sharp in the near future will open the eyes of the responsible parties to the enormity of their conduct."

TREATMENT OF OZÆNA BY ANIMAL GRAFTING.

In a research upon "Animal Grafting with the Skin of the Frog, in Losses of Cutaneous and Mucous Substance," undertaken along with Dr. Dubousquet-Laborderie, Barataux publishes observations upon ozæna, atrophic rhinitis with ulcerations, in which he obtained a complete cure by engrafting the skin of a frog over the ulcerated surfaces. He has thus treated eleven patients having ozæna and ulcerated non-specific rhinitis. In all these subjects he employed ten to twenty grafts, of which more than half have succeeded, and all the patients have derived much benefit from the treatment. He has always succeeded in obtaining a smooth mucous membrane. He takes the frog's skin from the interdigital membrane, the nictitating membrane, the belly, the lateral parts, by scissors, and places upon the raw surface with forceps, or by a special pipette.

NOTES AND COMMENTS.

THE MODERN TREATMENT OF COMMON DISEASES.

Amenorrhœa.

Chloride of ammonium (gr. ivss—gr. xv several times daily) is commended by Anstie and Cholmeley as an emmenagogue. As an emmenagogue and to relieve menstrual colic, Pitschaft recommends borax, though some doubt its efficacy:

R Boracis.
Aque amygd. am..... āā 3 j
Aque melisse..... 3 iv
M.—A tablespoonful hourly.

A famous emmenagogue is the elixir pro-prietatis Paracelsi, composed of:

R Aloe.
Myrrh..... āā 3 ss
Croc *..... gr. xv
Spirit..... 3 v 9 ij
Acid. sulphur. dil..... 3 ss

* [Trousseau says it is a fact of public notoriety that women engaged in picking saffron suffer from frequent attacks of uterine hemorrhage.]

The iodide of iron and saccharated iodide of iron are also widely used. Brera recommends a vaginal injection of water of ammonia, gtt 5—15 in 3 xv—3 iv of mucilage or milk. Kopp prescribes the following:

R Inf. summitat. sabinæ..... 3 vj 3 iij
Boracis..... 3 j
Sacch. alb..... 3 vj
S.—One tablespoonful three times daily.

Tavignot's prescription is:

R Phosphori..... gr. iss
Ol. amygdal.
Ol. cacao..... aa 3 ij
Flor. malvæ pulv..... q. s. ad pil. No. 100.
Sig.—4-6 pills twice or three times daily. [*Dose too large.*]

In suppression or retention of the menses, Fuchs gives:

R Ol. sabinæ..... 3 ss
Ol. terebinth. rectific..... 3 viiss
M. S.—Apply to the inner surfaces of the thighs.

Lebert's formula is:

R Ol. sabinæ.
Ol. rutæ..... aa 9 ij
Sacch. albi..... 3 vijs
Dissolved in aque dest..... 3 v
Add syr. sacch..... 3 vijss
M. S.—One tablespoonful every two hours.

As an emmenagogue in chlorosis, Oesterlein advises:

R Myrrh.
Aloes.
Ferri pulv..... aa 3 j
Extr. valerian..... q. s. ut ft. pil. No. 100.
M. S.—Five pills three times daily.

Common Errors in the Treatment of Skin Diseases.

Dr. George H. Fox, of New York, read a paper on this subject before the Montreal Medico-Chirurgical Society. The great error made by practitioners in treating skin diseases, he said, is failure to treat the patient: the disease is treated, not the patient. He considered attention to diet as most important. There should be a radical change both in the quantity and quality of the food. A dietary should be given the patient. The majority of the patients improve on starvation diet. He advised his patients to increase the quantity of fluids, and decrease the solids; to eat less and to exercise more. He gets the best therapeutical results from a vegetable diet in the treatment of inflammatory skin diseases: a meat diet congests the skin, a vegetable diet lessens congestion. He is in the habit of restricting meat in winter, and forbidding it in summer. In giving directions to patients, it is better to tell them exactly what to eat, instead of what to avoid. Water should be taken sparingly with meals, and in quantity after meals. Of local applications very few are needed. Arsenic, Dr. Fox said, is used too much by general practitioners in the treatment of skin diseases, and is a much overrated remedy.

The Treatment of Internal Hæmorrhoids by Injection.

Dr. Q. A. Shuford, of Tyler, Tex., sends the following communication to the *Medical Record* of June 25, 1887: "In the treatment of internal hæmorrhoids by submucous injection, it is necessary, in the first place, to have an instrument that can be introduced with the least amount of pain, and so constructed as to expose as much of the mucous membrane as possible. When a tumor is discovered, the speculum should be manipulated so as to bring the centre of the tumor into plain view, and the needle should have a guard near the point, so as to prevent it from entering too deeply. For small tumors I inject from three to five drops, and for larger ones from five to eight drops of the following mixture: Rub well together one drachm of salicylic acid and one and one-half drachms of glycerine, and add two drachms of carbolic acid; then rub together one drachm of borax and one and one-half drachm of glycerine, and mix the two thoroughly, allowing the mixture to stand until clear. The chemical changes and *modus operandi* of this combination I do not know; but I do know that internal hæmorrhoids treated in this way become atrophied, shrink

up, and peel off without pain, inflammation, or suppuration. I have never had any trouble nor heard any complaints from patients so treated. The two essential points in the treatment of internal hæmorrhoids are: first, an instrument that will bring the parts to be treated into view, and that without pain; and, second, a remedy that will completely destroy the pile, while leaving the mucous membrane in a healthy condition. An interval of from eight to ten days should be allowed to elapse between the injections, so as to give the mucous membrane time to become toughened. The injections cause almost no pain, and do not prevent the patient from pursuing his ordinary avocations." Dr. Shuford reports several cases treated after this method, and adds that he has treated nearly one hundred, of varying degrees of severity, and in none has he seen any inflammation or suppuration following the injections.

Warm Ether as an Anæsthetic.

Dr. M. W. Hobbes advocates, in the Cincinnati *Lancet-Clinic*, the advantage of warming ether previous to its administration in the production of anæsthesia. He and Dr. Taylor have tried the method in upward of thirty cases, and he writes that the patients not only came under the influence of the drug more readily, but they also recovered more rapidly and pleasantly from the anæsthesia than patients generally do who have been brought under its influence in the ordinary way of administering ether cold.

Sedative Compound.

The following formula is commended by J. S. Dorset, M. D., Superintendent Texas State Lunatic Asylum:

M.	Hyoscine hydrobromate, 1-50 gr.
	Paraldehyde
	Oil almond..... aa, 2 dr.
	Chloroform..... 10 m.
	Oil cinnamon 2 m.

M.
This medicine given at bed-time in drachm doses, in a great number of cases, is all that is necessary to secure a quiet, refreshing night's rest. The patients are not so nervous the next morning and are ready to take a good breakfast. He submits this formula to the superintendents of lunatic asylums for a fair trial, as a substitute for the chloral, which we feel is not good for the already diseased brain of a lunatic. He states that it is of especial value in wild, noisy cases, when sleep cannot be induced without much danger.—*Texas Courier Record*, June, 1886.

CORRESPONDENCE.

Improvements in Leg Holders.

The following interesting correspondence is self-explanatory. Incidentally it illustrates the value of the REPORTER as a medium for the interchange of practical ideas by practical physicians.—EDITORS OF THE REPORTER.

DR. THOS. B. MCBRIDE:

Dear Doctor:—In THE MEDICAL AND SURGICAL REPORTER for June 4th., I notice a cut and description of your apparatus; or what some authors have termed a Gynæpod.

By some strange coincidence our thoughts bent on the same object, have brought us to almost identically the same result; and as I was interested in the description of your appliance, thought that possibly you might be in mine, so take the liberty of writing you. Two years ago next October I brought my class in Gynæcology the apparatus that I was then using, and had made myself; which consisted of a straight hickory rod which was passed under the knees, and fastened around the neck by a band of webbing similar to yours. My objection to this appliance was that it required a little too long time to disengage, should emergency arise, and had to be carried as a separate bundle, and the less appearance of paraphernalia brought into the sick room the better the effect upon the patient. I set about to improve it, and a year ago had made the apparatus which a number of physicians in this city are now using. The principle is the same, the rod passing under the knees, instead of being of wood, is of iron tubing, nickle-plated, bent at each end, as in your cut; in the centre is a hinge which allows it to be folded together when not in use; the buckles for regulating the length of webbing are at juncture of webbing with strap; at the extremity of each strap is a steel snap which clasps into a ring at each end of horizontal rod, which may be unclaspd in less than a second if necessary.

To the left end is a little appliance in which to insert, when wanted, an upright rod with hook at top to hang a fountain syringe to, for irrigation, (or, as I frequently apply it, for checking hemorrhage by hot water); a Sim's speculum may be held in place by an elastic band from centre of horizontal bar. The whole apparatus fountain, syringe and all, I carry in my hand bag with the other instruments.

Yours cordially,

JOSEPH HAVEN.

Chicago, Ill., June 13th, 1887.

PROF. JOS. HAVEN, M. D.:

Dear Doctor: Your favor of the 13th duly received. As you say, it is by a strange coincidence we should both have centred our thoughts on the one idea and the outcome be so closely allied. When I showed my apparatus quite a number expressed surprise that it had not been thought of before, as it was so simple. But now I have to yield that you have had your invention in use before I even thought of mine, as it was only last January I had the first made. I must concede also that you have added to the utility of yours by the several improvements mentioned. The idea of a hinge was suggested to me by a number of physicians, and it has been added since about May 1. The cuts published do not show this, as they were made from my original apparatus. Another change was made by adding to the length of the ends of the semi-circles, making them extend from one to two inches above the level of the shaft. Again: The arrangement by which your apparatus is fastened is superior to mine, but I find no trouble in disengaging it by simply lifting the thigh out of the crutch. I take the liberty of handing your letter to the Editors of the MEDICAL AND SURGICAL REPORTER for publication, as this is about all the benefit we, as physicians, derive from being inventors. In fact, doctor, I am out of pocket and lost considerable time, in getting my appliance to its present imperfect state. I am, very truly yours,

THOS. B. MCBRIDE.

Homœopathy.

EDITORS MED. AND SURG. REPORTER:

Sirs:—I notice on page 34, volume lvii., No. 1, July 2, 1887, of your paper a note headed, "Homœopathy as it is." Please allow me to make a few comments upon it.

The *Medical Times* is not and never has been a homœopathic journal: it is of the worst type of *mongrel*. It is too true that it is almost impossible to find a teacher of homœopathy in our so-called Homœopathic Medical Colleges,—this is the reason why there is such dense ignorance of what homœopathy is among medical men at large, and why it is almost impossible to find homœopathic physicians who are truly such under the age of 35 or 40 years.

Unprincipled and ignorant men who do not know the first principles of the law of cure, claim the name and shout for it because they know it "pays;" and their "broad

and liberal" methods and principles are the strongest proofs of their ignorance and laziness.

"High-dilution homœopathy" is a misnomer—there are no "high dilutions." The educated homœopath never uses the word "dilution:" that is the stamp of ignorance of the fundamental principles.

Please do not advocate the teaching of pseudo-homœopathy of the Allen, Hughes and Dudgeon stripe in colleges. But if you would seek to elevate the medical profession, or give it a knowledge of what homœopathy is, let the Organon of Samuel Hahnemann be taught by a competent teacher who knows and understands it *himself*, and you may rest assured that "we" most emphatically "*do* hold that homœopathy *is* the *exclusive* and *only* law of healing."

H. HITCHCOCK, M. D.

Newark, N. J., July 6, 1887.

[The above letter was sent with an urgent request to publish it in the interest of fairness. We do so with pleasure, as we desire that everyone who is concerned in such a discussion shall have a chance to present his views in a fair and temperate way. Of course we do not thereby endorse the views of our correspondent.

—EDS. OF THE REPORTER.]

Fees of Veterinarians.

EDS. MED. AND SURG. REPORTER:

Please see page 767, No. 24, 1887, MEDICAL AND SURGICAL REPORTER, and note what is said about the remuneration of veterinary surgeons.

Allow me to say that the paragraph in question is calculated to cruelly deceive young men who may incline to the idea of becoming veterinary surgeons.

From personal observation in a number of Western States, I must say that it is a rare exception for a veterinary surgeon to collect \$100 per month, and many do not collect half so much for purely professional work, and are *forced* to give some attention to other matters in order to secure a living. Doubtless, in *some* of the Eastern States, veterinary surgeons are better paid; but, in the West, such men, now, are *pioneers*, and must submit to a pioneer's lot or quit the profession.

Of course I do not refer to *irregulars*, but "regular" graduates of first class veterinary colleges.

Fraternally yours, J. C. SMITH.

Austin, Texas, June 17, 1887.

"Sweet Are the Uses of Adversity."

An esteemed and philosophical correspondent in another State sends us, without comment, the following jotting:

"It occurs to me that the poverty of physicians, which is proverbial, is simply in accord with Divine or Natural economy. The physician who becomes financially independent becomes less valuable to the community in which he resides. In proportion as he increases in wealth does he decrease in importance as a physician. Few practitioners would bear the ills and perplexities of their practice if situated so as to live independent of it. There are, however, wealthy specialists whose practice continues to be lucrative and not as annoying as that of the general practitioner, who find it pleasant and profitable enough, to keep abreast with the progress of their specialty."

NEWS AND MISCELLANY.

A Clergyman on the "Faith Cure."

In a recent sermon on this subject, Rev. E. C. Ray, of Hyde Park, Ill., says: "Apparent cures are often followed by a relapse, temporary improvement by permanent decline. From reported cases of cure we must deduct many of unreported relapse: it is not in human nature, when a wonderful cure has been published abroad, to follow it up with an account of the relapse coming afterward. Mistaken diagnosis accounts for many supposed cures. Physicians often, patients more often, mistake the nature of a disease. Temporary swellings are called malignant tumors or cancers (thus cancer-doctors get their reputations); hysteria simulates almost every other disease, so as to deceive even the most elect of doctors; dyspepsia produces symptoms of heart-disease or other deadly illness. There can be no question that a large proportion of faith-cures and mind-cures, and a considerable proportion of cases under ordinary medical treatment, are cases of mistaken diagnosis, the disease being less serious in its nature than was supposed. Mistaken prognosis accounts for many cases; mistake as to what would be the outcome of the disease if no curative methods were employed. It is a truth seldom recognized by patients, though well known to physicians, that in most cases not hopelessly fatal from the start, there is from the start a strong tendency toward recovery. Dr. Austin Flint, Sr., than whom perhaps no abler physician has lived in this land, always urged upon his students the truth

that not drugs, but *vis medicatrix nature*, the healing-power of nature, is the means of recovery. The wise physician and nurse seldom attempt more than gently and humbly to assist Nature in her curative processes. Let me add the statement of a conviction derived from some years of such close scrutiny of medical practice of various schools as a pastor has good opportunity for,—a conviction agreed to, I think, by most physicians:—The benefit of medicine is often not its direct action upon the disease or upon the body, but its action upon the mind, and through that upon the nervous system and the whole body, stimulating faith, hope, expectation of recovery, good cheer, which are probably nature's mightiest remedial assistants."

Transplantation of the Cornea.

Dr. T. Webster Fox, of Philadelphia, sailed Wednesday last to visit the clinic of Von Hippel, who has recently succeeded in transplanting the cornea of the chicken upon the human subject in three cases of corneal leucoma. A full report upon this operation, together with Dr. Fox's own experiments, will be published in an early number of the REPORTER.

Hygienic Handwriting.

Schubert, of Nuremberg, has made a careful study of various kinds of script, and the bearing which the use of each has upon the hygiene of the eyes among children, and the following are his conclusions:

As a practical conclusion to be drawn from his observations, Schubert lays down the rule that all children should be taught a perpendicular handwriting. Even if the erect median position of copy book be not actually better than the oblique median, still the teacher cannot tell when inspecting writing done at home what absurd position may have been adopted in writing it, if the child is permitted to write anything but perpendicular letters. These latter can only be executed in the erect median position. It may be possible for adults to write more rapidly a slanting than a perpendicular hand, but children are not required to write rapidly, but in a manner that does not tend to deform their vertebral columns or their eyes. In many countries now-a-days, and in times past, perpendicular handwriting alone obtains, and Schubert appends a series of fac similes of German handwriting in every century from the 8th to the 18th inclusive. From this it is seen that slanting letters were not adopted to any extent until the 17th century.—*Ophthalmic Review*.

Condensed Pharmacy.

Some of the Paris pharmacists feel uneasy about the growing popularity of the medicinal alkaloids. They say that the time is not far distant when Sydenham's notion that the active usefulness of an entire drug store would sometime be carried around by doctors in the heads of their canes, is likely to be realized. The signs of the times certainly point to a future for medicine, in which composite drugs will be cleared of their useless components, and it does seem possible that the 8 ounce bottle prescription business may fall off a little. But as people become acquainted with the proper uses of the alkaloids they will certainly employ them much more frequently than they now use the massive mixtures of the older codices. A better instance of this than is shown in the growing popularity of citrate of caffeine, to which your correspondent has already referred, could hardly be cited. And then the pharmacist does a great deal of business with which the prescriptions of doctors have nothing to do. This kind of trade will increase with the exigencies of civilization. No living pharmacist will see the day when doctors will carry drug stores in their hats.—Paris correspondent of *Pharmaceutical Record*.

Terrible Mortality in New York City.

The deaths reported to the New York Health Board, on July 3d, numbered 256. This is the largest figure for one day since 1876.

Duties of the Druggist.

A correspondent of the *Western Druggist* in 1886 raised the question whether it was justifiable for a pharmacist to alter an excessive dose prescribed by a physician when uncertain whether such dose was prescribed, and unable to settle the matter by inquiry of the physician. As the following New York decision shows, this is not only justifiable, but it is the pharmacist's legal duty: A New York lady gave a pharmacist a prescription for a large quantity of laudanum, and at its foot was the following request by the physician: "Please give to bearer sixty drops in the store." The pharmacist declined to administer such a large quantity. He gave the lady ten drops because she was in pain; she begged him to give her such a dose as he would not be afraid to personally administer to her. Soon after these events the lady began a suit against the pharmacist in the Court of Common Pleas. She claimed \$10,000 damages, alleging that if he had given

her sixty drops of laudanum as requested she would have been saved from a miscarriage and its effects. The defence was that the ten drops of laudanum given by the druggist could not have affected her more than to temporarily lessen her pain, and that a pharmacist is not bound to personally administer dangerous drugs upon the order of a physician, his duty being simply to prepare medicines under the direction of physicians. Judge Beach sustained this view of the duty of a druggist, saying that a druggist would incur liability to indictment for manslaughter for having knowingly administered a drug or medicine which produced death.—*Western Druggist*.

Items.

—The *Lancet* computes that between five and six hundred individuals were treated for various casualties during the procession in London on Jubilee day.

—Some hilarious young men at Pittsburg dosed the drink of one of their companions so largely with croton oil "in fun" on the Fourth that he has since died.

—"Do you rectify mistakes here?" asked a gentleman, as he stepped into a drug store.

"Yes, sir, we do, if the patient is still alive," replied the urbane clerk.

—"In the interest of the health of the community," a New Yorker informs the sanitary authorities of his city "that on Friday last a large snake came through the faucet."

—Bystander—Doctor, what do you think of this man's injuries?

Doctor—Humph! Two of them are undoubtedly fatal, but as for the rest of them time alone can tell.—*Texas Siftings*.

—Dr. W. Allan Jamison and M. Alexander Edington, of Edinburgh, announce in the *British Medical Journal*, of June 11th, that they have discovered a specific bacillus of scarlet fever which they claim is the specific cause of this disease.

—The chief of police of Chicago has issued orders giving the vehicles of physicians precedence at bridges, along with the mail and patrol wagons, ambulances and fire apparatus.

—To hear the doctors talk, one would suppose ice-cream to be a compound of deadly poisons, among which ptomaines, oxide of zinc, lead and various adulterants find prominent place. But it rather upsets one's faith again to see the same doctors quietly swallowing large quantities of the dangerous stuff.

—An instance of the late Senator Carpenter's wit, and at the same time a striking illustration of "the ruling passion strong in death," occurred when he lay on his death-bed. He inquired of his attending physician what was the matter with him, and when the doctor informed him that it was "a stoppage of the colon," the Senator remarked, that "I am glad it is not a full stop."

—Apoplexy, induced by excessive laughter, was given at the inquest as the cause of the death of a young woman, in Sheffield, England, lately. She had been highly amused at the predicament into which a neighbor got, and broke into a fit of laughter which continued until she fell to the floor unconscious, death following shortly afterwards.

—A NEW KIND OF INSOMNIA.—A professor in a certain college, who complained of insomnia, was advised to consult a celebrated physician. He did so, and the latter, after a thorough examination of all the vital organs, pronounced the professor absolutely sound. "I am at a loss," the doctor said, "to account for it. You seem perfectly well. Perhaps something is preying upon your mind?" "Oh, no," said the professor, "nothing at all." "Perhaps you have some business cares?" "No: nothing of that sort." "And yet you say that you get no sleep at night?" "Oh, no! I never said that. I'm all right at night; but it's insomnia in the daytime that bothers me!"

—Statements have been made at various times that the seeds found in ancient Egyptian tombs have germinated, but it is pointed out by Mr. George Murray in *Nature* that competent botanists have universally condemned as worthless the evidence given in support of the alleged germination of mummy seeds. For example, the mummy wheat of one well-known traveller grew up as oats (!) a plant which was unknown to the ancient Egyptian, but which is now cultivated in the country. The Arabs are understood to mislead travellers.

—The recent serious and nearly fatal illness of Prof. Billroth, from which he is now convalescent, consisted at first in a sharp attack of bronchitis which confined him to his bed. Then acute pneumonia supervened. These conditions, combined with fatty degeneration of the heart, brought about a state of alarming prostration. He appears to have derived most benefit from inhalations of pure oxygen, which were prepared for him every day.

—Lanolin was official in a Madrid Pharmacopœia in 1797.

OBITUARIES.

DR. HENRY CARPENTER.

Dr. Henry Carpenter, oldest practicing physician and head of his profession in Lancaster county, died on July 9, 1887, in the 68th year of his age, of paralysis. He was first stricken on April 13th, and received the third fatal stroke July 3d.

Dr. Carpenter was born on December 10, 1819, in Lancaster. He came from a race of physicians. The hanging lantern, dated 1698, now in his possession, was brought over here by his paternal ancestor, Dr. Henry Carpenter (Zimmermann), who came to Germantown from Switzerland in that year, and moved to West Earl, in 1717.

Dr. Carpenter graduated at the Pennsylvania Medical College in February, 1841, when he returned to Lancaster, and began practice in the office which he occupied during all of his practice, and which his father formerly occupied as conveyancer. He was one of the founders of the Lancaster County Medical Society in 1844, Secretary from its organization for many years, and its President in 1855. He was Secretary and Vice-President of the State Medical Society, and one of the Board of Censors for the Eastern District of Pennsylvania. After he was fully started in his profession he discovered that the obstetrical forceps then in use, those of Hayden, Smellie and Baudelocque, were not all that could be desired, and in 1843 he drew plans for forceps that were manufactured for him in Philadelphia by Mr. Gemrig, and which he used for forty-four years. His early training rather cultivated a taste for obstetrics, and, while he had no specialty, he nevertheless had a very large obstetrical experience; those in his own individual practice, together with consultation, amounting to nearly 5,500 cases. While Dr. Carpenter devoted much time to obstetrics and gynecology, he was a practical surgeon in the most general acceptance of the term, having operated extensively in almost every affection which calls for surgical interference. He was never connected with any of our public hospitals, and therefore his extensive experience in operating for strangulated hernia seems the more remarkable. Up to July 1, 1871, the ledger shows that he had 246 cases, and these embrace every variety of this affection. One of the most brilliant operations he ever

performed was the ligation of the gluteal artery, and so far as we have been able to discover there is no record of this having been done before in the State.

DR. LOUIS BOUDINOT HUNTER.

Louis Boudinot Hunter, Medical Director of the United States Navy, died recently in this city at the age of eighty-three. He was a native of New Jersey, and entered the Naval Academy in 1828, and in 1833 was attached to the frigate Hudson, of the Brazilian Squadron, as Assistant Surgeon. At the outbreak of the Rebellion he was Fleet Surgeon in the service off the coast of Brazil. After some service on the Retiring Board, he was rendezvoused at the Navy Yard in this city from 1863 to the fall of 1864, when he sailed as Fleet Surgeon of the North Atlantic Squadron. From 1866 to 1879 he was stationed at the Philadelphia Navy Yard, on the Board of Examination, and from 1872 to 1873 was attached to the Gray's Ferry Naval Asylum, being retired in the latter year with the rank of Medical Director, U. S. N.

DR. LEWIS B. HUNTER.

Dr. Lewis B. Hunter, medical director on the retired list of the U. S. Navy, died in Philadelphia on June 24th, at the age of 83 years. Dr. Hunter was a native of New Jersey, and was appointed an assistant surgeon in the Navy in January, 1828.

Changes in the Medical Corps of the Navy for the week ending July 9, 1887:

Medical Inspector, A. Hudson, detached from the "Trenton," and awaits orders.

Medical Inspector, W. K. Scofield, ordered to relieve Medical Inspector Hudson on the "Trenton."

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from July 3, 1887, to July 9, 1887:

Major Wm. S. Tremaine, Surgeon, ordered for examination by Army Retiring Board, at Governor's Island, N. Y. Harbor. S. O. 155, A. G. O., July 1, 1887.

Capt. J. O. Skinner, Assistant Surgeon, granted leave of absence for six months on surgeon's certificate of disability. S. O. 151, A. G. O., July 1, 1887.

1st Lieut. H. S. T. Harris, Assistant Surgeon, will be relieved from duty at Ft. Ringgold, Tex., upon the return of Assistant Surgeon W. F. Carter, and will then report to Commanding Officer at Fort McIntosh, Tex., for duty. S. O. 73, Dp. Texas, June 27, 1887.

ORIGINAL DEPARTMENT.

LECTURE.

ADDRESS ON OPHTHALMOLOGY.

BY C. S. TURNBULL, M. D., OF PHILADELPHIA.

Read at the Thirty-Eighth Meeting of the
Pennsylvania State Medical Society, at
Bedford, Pa., June 29, 1887.

Although the title of this address as announced would lead ophthalmologists to expect a specifically special paper on the subject, I have deemed it more fitting to bear in mind, and will attempt to answer the queries so often put by visiting colleagues: "Well, doctor, what is new on the eye?" With this idea in view, therefore, I present a *mélange* which at least will be practical, and, I hope, instructive, as I quote experience with especial reference to diseases of the eyes of children.

Red eyelids, so-called "weak eyes," with or without crusts, and loss of lashes, barometer-like, indicate faulty vision, or an error of refraction. Marginal eczema, as this form of inflammation of the lids is called, can be temporarily cured by local applications, but will be apt to return, because an error in refraction is generally the remote cause, and glasses must be fitted to remove the eye-strain.¹

As a local application, nothing is better than what is known as the "yellow salve," which is made as follows:

R Muriate of morphia.....1 grain
 Yellow oxide of mercury... 2 grains
 Vaseline.....3 drachms

S.—Mix thoroughly and dispense in a paint tube.

Unless this salve be properly applied, it is apt to be too stimulating, and will aggravate the trouble it is intended to relieve. Each evening the eyelids must be thoroughly bathed with warm water, until the crusts can be removed without tearing out the eyelashes. Having thus cleansed the lids from all secretions, they must be carefully dried with a soft linen cloth. Then the edges of the lids are to be thoroughly anointed with a small scrap of the ointment—a piece the size of two pins' heads. The following morning any superfluous salve may be gently wiped away with a dry cloth.

A "stye" or abscess of the Meibomian follicle is often a symptom of a *strained eye*, and, unless Job's comforters are cropping out all over the body, the sight should be carefully tested. Furuncles of the lids are to be treated the same as when found on other parts of the body, but must not be mistaken for styes. Neglected styes are the constant source of *tumors of the eye-lid*, and no such abscesses of a gland should be allowed to slowly subside into a deformity, when by hot applications or by free incision they can be evacuated spontaneously.

Obstructions of the tear duct are generally caused by irritation, and extension of inflammation from nasal disease, or by exposure. Most obstructions are at the mouth of the tear duct (punctum), and seldom

¹ As a warning to slovenly parents, Baudry (Arch. d'Ophth., 1885, Vol. VI., p. 55) notes the *transmission of syphilis* to two children by adults, who tried to remove with saliva the crusts along the margins of the lids due to blepharo-conjunctivitis. In both cases the chancre was situated near the inner canthus, once above and once below, near the lachrymal points.

require more than the slitting of the canal. Obstructions caused by nasal disease have their origin at the nasal end of the duct, and are usually accompanied by blennorrhœa of the lachrymal sac. Such cases call for treatment which, to be of avail, must be started in the nose. The secret of the successful treatment of inflammation of the tear sac and multiple stricture of the duct, is free slitting of the canal, and division of the mouth of the sac down through the bony foramen. In the majority of cases, astringent collyria, such as sulphate of zinc, 4 grains to 6 drachms of water, and thorough inunction of the nose, inside and out, usually effects a cure. More harm than good comes of the use of most forms of probes. Small probes are dangerous, as they make false passages, but where there is a decided stricture, free division and large probes make radical cures.

For the *removal of foreign bodies* from the cornea, we are blessed in the possession of "muriate of cocaine." With a two per cent. solution of cocaine, we can anæsthetise the eye and remove a deeply imbedded foreign body from the most sensitive cornea, without being obliged, as was formerly the case, to have resort to the speculum to hold the lids, the fixation forceps to hold the eye, and an assistant to hold the patient.

Concerning squint, or "cross-eye," much may be recommended as of practical worth, and laurels are likewise to be won in the *non-operative, or atropine*, treatment of young children. A few anatomical points must be recognized at the outset.

1. A pair of flattened eyes with a tendency to converge, deeply set in the head, more or less close together,—suspect *far-sightedness*.

2. A pair of prominent, bulging eyes, widely separated, with a tendency to diverge,—suspect *near-sightedness*.

3. One eye alone or both eyes alternately, or it may be at the same time, apparently attempting to hide behind the nose, means *convergent squint*, usually with far-sightedness, or far-sighted astigmatism, as a cause of defective sight.

4. One eye, or perhaps both eyes at the same time, wandering to the outer angle of the lids, towards the temples, means *divergent squint*, usually with near-sightedness, or near-sighted astigmatism, as a cause of defective sight.

Of course, there are exceptions to every rule. According to Stilling (Arch. f. Augenhk., Vol. XV., p. 73), strabismus consists in relinquishing binocular fixation, and placing one eye in its natural position of

equilibrium. If this is convergence, convergent strabismus results; if divergence, divergent strabismus; if it is a parallel position of the axis, an absolute strabismus cannot result. In the majority of cases of hypermetropia, convergence is the position of equilibrium, in myopia it is divergence.

The family physician is often called upon for an opinion concerning the nature of a *squint suddenly noticed* in some little one; but he is usually at a loss how to advise or account for the deformity. It will be noticed in making the squinting child turn its eyes to one side or the other, that one eye will be possessed of more power to move, in extreme excursions, than the other. The eye possessing the greatest mobility is usually the squinting (non-used) eye. In order to compel service in the non-used eye, we usually dilate the pupil of the better eye, using for this purpose a four-grain solution of atropia, one drop every three days. Care should be taken at first, after throwing all work on the squinting eye and, as it were robbing the child of the sight of its good eye, that enough vision is secured to answer all ordinary purposes. By this method, usually practiced upon children between the ages of six months and four years, I have often been able to secure binocular vision and cure the squint; and, in cases where the sight has been very poor in one eye, been able to convert the squint into the "alternating form," which variety is the most successfully treated by operation.

If a child has been neglected up to its seventh or eighth year, and the squint is a decided one, there is nothing left to be done but to operate. *The success of all squint operations* depends upon the amount of sight retained by the squinting eye or eyes. If the squint be an alternating one, we may expect success and binocular vision. Concerning other cases of convergent or divergent squint, our success will be in accordance with the amount of vision which can be obtained from either eye, be the vision natural or acquired by the use of glasses. When there is no useful sight in the squinting eye, as is frequently the case, we operate simply for cosmetic effect, and must be satisfied with limited success. No other anæsthetic than cocaine is necessary in the case of adults or larger children, and this is a great comfort, as the operator can avail himself of the assistance the patient can render by moving the eyes as directed.

It is all important that patients should thoroughly understand the ultimate results sought when advising or operating for a

squint. Such an operation improves the vision only at times; generally it does not, but on the contrary impairs it for a greater or less length of time. When the squinting, non-used eye is called into use, and its indistinct image is fused with the distinct image of the fellow eye, it causes blurred and often, at the same time, decidedly painful vision. This unfortunate condition is known as muscular asthenopia.

Muscular asthenopia causes impaired vision, painful vision, or both. The pain caused by this sort of strain is of the same sort as that which we feel in the muscles of the arm and shoulder after carrying a heavy load. The muscles involved are the ciliary muscles (of the iris) and the motor muscles (of the globe).

Headaches in school children, which are generally frontal, although they may be referred to the occiput, are usually caused by defective sight, and only rarely by diseased eyes.

Acute diseases of the interior of the eye are rarely noticed in children until there is actual loss of sight and irreparable damage. Their onset is insidious, as there are necessarily no external symptoms. Children are more observant than people usually suppose, and we should not fail to give ear to their oftentimes significant remarks. Clouds and motes, with corruscations, flashes of light, and kaleidoscopic displays of rainbow colors, suggest retinal or choroidal irritation, and mean danger, as does the red signal light to the railroad man.

Photophobia, or dread of the light, *without accompanying conjunctival or corneal irritation*, means retinal irritation, and calls for prompt investigation and treatment.

Photophobia, with conjunctival or corneal irritation, on the other hand, is an ordinary symptom which can be readily accounted for and locally treated. This brings us to the consideration of—

Phlyctenular ophthalmia which, next to the purulent form, is the most annoying, harassing, and dangerous variety of eye disease to which children are subject. I will attempt to paint a picture frequently to be seen in the office of the family physician.

Fancy a baby, between the ages of six months and three years, carried into your office; the child is either screaming or has its face tightly pressed against its mother's shoulder; one little hand frantically clutches the dress of the mother, while the other with equal force clutches a pretzel, a stick of candy, or a piece of unripe fruit. Seating herself with a sigh, the weary mother forcibly

drags the screaming child from its shelter, and endeavors to turn its face towards you. The face picture is typical; the eyes are closed spasmodically tight by the swollen eyelids, and scalding tears run down over the cheeks, because the swollen nose cannot provide for the overflow; while, most significant of all, is the *swollen upper lip*, which looks as if recently stung by some insect.

The mother's complaint is, "Doctor, I cannot get anything done about my house; this child takes my entire time; when I am not nursing it, it is either screaming or sleeping with its face buried in the pillow; I am compelled to keep the room dark, and am quite unable to please or manage the child." Casual questioning elicits the following routine history, which goes to prove that it would not be much out of the way to term this condition *reflex gastric ophthalmia*. The digestion is always disordered and the appetite capricious; the child is given both tea and coffee and very little, if any, milk; sweet things *ad libitum*, roast meats, boiled potatoes, pie, and a long list of always indigestible food. The child always sleeps on its face, and the only time either it or its mother seems to be able to secure any rest is from sundown till bedtime. As a rule such children, to use an inelegant but expressive phrase, are "bosses of the situation;" that is to say, "spoiled." They sleep with their faces buried in the wet pillow, which acts as would a warm poultice, and encourages congestion and swelling.

Treatment in this disease depends upon the care and patient pains the doctor is willing to bestow, the faithfulness of the mother, and the firmness she proposes to exercise in the execution of the doctor's orders. It is essential that the child should be fed regularly upon simple food, such as milk, broth, soft boiled eggs, and rare meat. Starchy foods are to be avoided. Sweets of all sorts, as well as tea and coffee, are to be tabooed. The apartments must be kept dark and the child made to lie on its back. When this plan of treatment is once thoroughly instituted, half the fight is over.

Locally the "yellow salve" is to be rubbed on the edges of the eyelids at bed time, and oxide of zinc ointment may be used for the excoriated nostrils and face. Solution of atropia, one to four grains to the ounce, may from time to time be dropped into the eye, according to the age of the child, and also depending upon the amount of lachrymation. A 2 per cent. solution of cocaine may be used, or a salve made of vaseline and cocaine and atropine in combination.

Constitutionally I never fail to prescribe the following mixture to be taken at bedtime, with an occasional dose of calcined magnesia because of the especial inactivity of the liver in all such cases:

R Powdered blue-mass. 10 to 30 gr.

Syrup of rhubarb. 1 to 2 oz.

M. Sig.—Shake well, and give a teaspoonful or more at bedtime.

After this has been used for a week or two, I order five drops or more of the syrup of iodide of iron, three times a day, never forgetting to prescribe bromide of potassium, and syrup of lettuce, (Aubergier's) or some equally good sedative mixture.

In very young children, during dentition, or where flatulence and constipation are persistent and annoying, I cannot laud too highly the old *mistura foetida comp.* (De-wees's Carminative). I have described the appearance of the child, taken for granted the condition of the eyes behind the firmly-closed lids, suggested treatment, and given explicit directions; but I have purposely said nothing until now as to how one should make an intelligent inspection of the eyes proper, that is, of the conjunctiva and cornea. You will find that after a mother has been compelled to assist you in holding her child, whilst you force the eyelids open, she will, as a rule, be so thoroughly demoralized, that in her anxiety to pacify it and get out of your office, she will be quite sure to forget all that you have told her. For this reason a few directions as to the method of holding such children, so as to examine and treat their eyes under circumstances such as we have just mentioned, will not be out of place. The trick is well worth knowing, as a good-sized unruly child, with a weak mother and an inexperienced doctor, where the eyes are to be forcibly examined and then treated, is a veritable "bull in a china shop." The person holding the child is to sit directly opposite the physician, their knees touching. The child is to be laid on its back, its body resting on the assistant's knees. Both of its feet are to be turned to one side and tucked under the assistant's right arm; this leaves the assistant's hands free to hold those of the child. To protect the doctor's knees a heavy towel is spread over them, and upon this the patient's head rests. In extreme cases the patient's head may be pushed down and held firmly between the doctor's two knees. His hands are then free so that he may commence by instilling cocaine-solution (rarely satisfactory) and, with thumb and forefinger, or with any good lid-retractor, he can forcibly open the eyelids and expose the globe. In

the disease under consideration, he will find a pustule on the conjunctiva, or the cornea, or it may be on both, or the corneal pustule may have developed into an ulcer. The pupil is always contracted, and it is needless to say that photophobia is marked and lachrymation profuse. In either condition the treatment is what I have suggested, excepting one other reliable hygienic point which I have thus far neglected to mention. The morning sponge-bath is a most valuable addition, and still better is the therapeutic shock to be obtained by alternate spongings with hot and cold water. In the case of larger children, frequent dippings of the face in a basin of cold water will assist materially in controlling the spasm of the eyelids.

This disease is essentially one which occurs in summer, and when as it generally does, it accompanies dentition, or gastric or intestinal disease, is greatly to be dreaded.

Scrofulous ophthalmia. The only disease of the eye for which the disease just described might be mistaken is what is known as *scrofulous ophthalmia*. This insidious inflammation commences with what appears like a pink nodule, or phlyctenule, on the conjunctiva, and might readily be mistaken for the disease we have just described. Close inspection will show that the red spot on the conjunctiva is not a pustule, but a glandular swelling accompanied by little or no conjunctivitis, photophobia, or lachrymation. In the majority of cases, as a guide to diagnosis, we have the scrofulous physiognomy; i.e., flat sunken nose, and notched teeth. Should this red spot have been in existence for some time, there will likely be shading from it a cloudy patch of more or less density caused by infiltration between the layers of the cornea. This disease may or may not be accompanied by iritis, which in every instance is plastic. One characteristic point, and never absent symptom, is the peculiar coppery red appearance of the inflamed conjunctiva at the limbus, between the cloudy spot and the inflamed gland. Arlt called this "*lymphatic inflammation of the cornea, or scrofulous keratitis*," and always insisted upon inherited syphilis as its cause. I feel satisfied, however, that this form of eye disease is seen in tuberculous subjects as well. It usually occurs between the ages of eight and thirty-five years, more frequently at the age of puberty. In any case there is one form of treatment, which in my hands has proven almost a specific. I have adopted the German method, and in prescribing I always commence with mercury, which I *gradually* push to salivation, and follow it with the

iodide of potassium, *gradually*, repeated for emphasis, creeping up from five to sixty grains three times a day. In some cases, for children between the ages of eight and twelve years, I have administered as much as one-sixteenth of a grain of the biniodide of mercury every hour for from one to twelve months, and at the same time used inunctions of blue ointment twice daily without being able to notice the slightest constitutional effects. Nevertheless I feel fully satisfied that these peculiar cases, not only do well, but thrive upon a well-managed course of mercurial treatment. As a precaution I always see that parents or guardians understand that cases such as we have described will require months, yes, even years of prolonged and tedious treatment, and incessant looking after.

Opacities of the cornea, the "cataracts" of the laity, if unaccompanied by conjunctival irritation, must be regarded as we regard scars upon the body, and are in a general way incurable. They may not be discernible save by oblique illumination, but all cause badly impaired vision and strabismus or squint. If they should be the cause of poor sight in a hyperopic eye, the squint will likely be a convergent one, and *vice versa*. They also cause dread of strong light, and are oftentimes a source of annoying and constant pain, and therefore in treating corneal disease, do not be satisfied when all redness leaves the eye, but when the opaque spot remains on the cornea continue your active treatment until nature fills in a clear cornea, and removes the cicatrix.

Concerning *cataract* operations much may be said. Every operator is an advocate of his own method, or it may be of his modification of somebody else's method. Suffice to say, that the percentage of success, in a general way, is so great that we are fully justified in assuring our cataract patients of having eight chances in ten of success. The more unruly or complicated cases are more operated on in a conservative manner. A preliminary iridectomy is made, in two or three weeks later the cataractous lens is extracted, and by this means the operation is robbed of most of its dangerous elements. On the other hand in uncomplicated cases the more heroic and skilful operators do not interfere with the iris; i. e., make no iridectomy, but remove the lens through the dilated pupil, being bold enough before commencing the operation to wash the eye and its tutamina with soap and water, and inject an antiseptic solution into the eye.

In operating for cataract we must be par-

ticularly careful where solutions of cocaine are used as a local anæsthetic, and not expect to do more than render the conjunctiva and cornea anæsthetic. If we use enough of a two per cent. solution of cocaine to affect the iris, there is risk of having the corneal flap shrivel, and I have concluded that unless an operator be satisfied with anæsthesia of the conjunctiva and cornea, he must frequently sacrifice an eye. I seldom bandage an eye after cataract operation now, preferring to use adhesive plaster (as first suggested by Dr. R. J. Levis) cut into ovals to fit the upper lid.

Cataracts are artificially ripened by massage, when for several reasons we do not wish to wait for Nature; and a puncture of the lens or a preliminary to iridectomy is often made for the same reasons.

In examining the eyes of those past middle life, a two per cent. solution of cocaine is the safest, and therefore the best mydriatic, because of its evanescent character and its tendency to reduce intra-ocular pressure. In private as well as clinical practice, I use cocaine, in two per cent. solution, for all preliminary examinations, never using any other mydriatic, except when I wish to paralyze the accommodation. Solution of atropine is too heedlessly used, and the number of cases of atropine glaucoma are steadily increasing, as can be found out by looking up the literature of the subject.

For glaucoma we have a potent local remedy in the form of "eserine," the alkaloid of the extract of calabar-bean, which may be instilled in solutions of varying strength (gr. $\frac{1}{8}$ to $\frac{1}{4}$ to $\frac{3}{4}$) and by this means an eye may either be cured or at least kept under control until the surgeon is able to operate (make an iridectomy, paracentesis of the anterior chamber, etc). In fact, numbers of cases have been entirely cured by the instillation of this drug alone.

In detachment of the retina occurring in myopic eyes I have had most gratifying success by treating this condition as if it were a traumatic sub-retinal effusion, due to other causes than myopia, and employ a full specific course with absolute rest. I can recommend the use of mercury pushed to constitutional effects, both by pill and by inunction, followed by iodide of potassium, not forgetting to recognize the like effect of jaborandi internally, or pilocarpin hypodermically.

In the selection of spectacle frames (note I do not say spectacles) opticians are universally careless and those who prescribe glasses are often culpably negligent. If the spec-

tacles are intended for reading and *near work*, the bridge-piece is oftenest made *shallow* so that in casting the eyes down, the lower edge of the lens is in the way, and seeing over the top of the glasses is an impossibility. If the spectacles are for near work they should have a deep bridge-piece, which will enable the wearer to drop the eye for reading, &c., and have it strike the centre of the glass, and the next moment, without moving the head to look over the glass, and in the distance. If on the other hand the glasses be for distance, they should have a *shallow bridge-piece*, and be set well up, in front of the eyes, so that the wearer cannot do otherwise than look through them for the distance, and under them while walking, &c. Where double lenses are used, the upper half for near vision their manufacture must in every case be intrusted to a skilled optician. Each half glass must be ground from a whole lens in order to secure a proper optical centre. One half of a lens will not do. The great want of care displayed in the manufacture of this form of glass has been the cause of bringing it into disfavor.

Protective glasses are best made of "No. 4, London smoke" glass. Too light a shade does not offer protection enough, while on the other hand, too dark a shade causes a severe and sudden transition from dark to light. Oculists for many reasons prefer the smoked, that is dark glass, and so, if left to themselves, do the majority of persons. Take for instance, one hundred purchasers of protective glasses, as they select them from the vendor on the sunny seashore, and ninety of them will select the dark or "London smoke." Green at one time, copying after nature, was the fashionable color. Afterwards everything was "blue-glass," but experience has selected the smoked.

There is another sort of protective glasses; that is those worn to keep foreign bodies from damaging the eyes. For this purpose glass and mica, as well as wire gauze, has been used, especially in the older countries; but I am sorry to say our mechanics do not seem to know how, or to want to take care of themselves. In this country of profligate waste of money and life I am compelled to enucleate many damaged eyes, in the course of a year, which might have been saved by protective glasses.

To protect the eyes from the electric light, a glass is made, or rather spectacles are made, of a yellow or amber colored glass, which color has been found to absorb the irritating rays.

COMMUNICATIONS.

TREATMENT OF RINGWORM OF THE SCALP.

BY HERMAN B. ALLYN, M. D., OF PHILADELPHIA.

Ringworm of the scalp is an essentially chronic disease, since no case tends to spontaneous recovery; and, though a few may seem to remain stationary, in general the disease when left to itself may be said to grow progressively worse. It is, moreover, one of the most rebellious to treatment in the whole range of curable diseases.

The obstinacy of the disease seems to me to arise from two causes: first, because the spores of the *microphyton* are not so susceptible to the action of germicides as the spores of some other skin diseases; and, secondly, —the much more important reason—because germicides cannot easily be brought into contact with the spores, situated as they are in the shaft and root-sheaths of the hairs.

All children below the age of puberty are about equally susceptible to the disease. If a child were exposed directly to the contagion, and did not develop ringworm, I should be inclined to think it a personal idiosyncrasy. On the other hand, adults are nearly, though not quite, exempt. My own experience does not lead me to think that syphilitic or scrofulous children are more apt to develop the disease than healthy children; but in the scrofulous it spreads with much greater rapidity. Nor do I think that it is usual to find, in the scrofulous or syphilitic child, the disease in a peculiarly obstinate form.

Inasmuch as methods of treatment that have proven efficacious in the advanced stages of the disease would be so much the more curative in the earlier stages, I do not think it advisable to go over the list of remedies that would be applicable only to the less obstinate cases, such as iodine, sulphur, etc., etc., but will speak of those which may be considered applicable to the disease in general. The treatment, as in other skin diseases, is general and local.

General treatment consists in (1) the isolation of the cases; (2) good food, fresh air, exercise, bathing of the whole body, etc.; (3) regulation of digestive derangements, such as constipation, which, just as in eczema, tend to aggravate the disease; (4) the treatment of any constitutional condition, such as struma, syphilis, anemia, and the administration of general tonics when the system

is below par. In this connection it may be pertinent to remark that light-haired boys show the good effects of cod-liver oil better than dark-haired boys.

Local treatment is, however, by far the most important. The hair should be shaved from the scalp regularly once in two weeks. This enables the medical attendant to examine the head rapidly, and at the same time to detect any new spots in their earliest stages. Besides, when the head is shaved there is less danger of fresh spots developing. As a rule, lotions are more serviceable than ointments. As regards epilation, I think it is in all cases of decided advantage, because it at once removes great quantities of the fungus, and leaves the evil, so to speak, more porous. Many cases can, however, be cured without epilation, and as it is often painful it is not always wise to insist upon doing it.

Of the various lotions that have been used, I have found that suggested by Mr. Harrison, in the *British Med. Journal* for September, 1885, the most generally useful. It consists of two solutions, of which the following are the formulæ:

- R Potass. iodidi.....3jss;
Liq. potassæ.....ad. fl. ʒijj.
M. Sig. "No. I."
- R Hydrarg. bichlor.....gr. iv;
Sp. æth. nit.....ad. ʒj.
M. Sig. "No. II."

Moisten a rag held in a pair of dressing forceps in the first solution, and rub on the affected parts. After a short interval the second solution should be rubbed in, or simply daubed on, in the same way. The treatment is an ingenious one, producing the biniodide of mercury in contact with the spores, the skin, root-sheaths and hairs having been previously softened by the liquor potassæ. The second solution should be made up fresh at least every three days, as the bichloride precipitates, and the solution then becomes not so effective—just why, I cannot say, unless it be on the general principle that a clear solution is more penetrating than a mixture. As can readily be imagined, the treatment is a painful one. When thoroughly applied, as it should be, it makes the scalp very sore; but when not too much of the first solution has been used, the sores remain clean and healthy looking, and readily heal up. When the solutions have been used too freely, yellowish or greenish-black crusts form on the scalp, and are not easily washed off. This is more apt to occur when the hair has not been

kept short. Cosmoline, or, still better, an ointment of ammoniated mercury, ten grains to the ounce, well rubbed in, loosens and softens these crusts, so that a soap and water bath readily cleans the scalp. It is also a good plan to occasionally discontinue the solutions, and rub the scalp for two or three days with some mild ointment, such as the one suggested; this serves to keep the scalp in better condition for receiving germicides, while the soothing ointment sometimes makes a wonderful change for the better in what perhaps before seemed a very disheartening case. Besides, by intermitting active treatment for a short time, until the scalp recovers its tone, one can better tell just what progress his treatment is making toward cure. From this it may be inferred that sometimes treatment may be too active.

While this treatment is in the average case of ringworm highly successful, there are objections to it. Its painfulness has been referred to. This may be stopped, after the application of the second solution, by a four per cent. solution of cocaine; but, unfortunately, cocaine will not relieve pain before or after the use of the second solution. It has also been urged that relapses are more common under this treatment than under others. Time is the only thing that under any treatment will inevitably tell whether a case is cured. Perhaps relapses have seemed more common, because this treatment works more rapid improvement than any other, leaves the parts cleaner, and hence leads the unwary to infer that the disease is cured. I must admit that I have on several occasions been unable to find any ocular evidence of disease, and yet the cases have relapsed. The only safe rule is to subject each case, dismissed as cured, to daily inspection for six weeks or two months.

There are several classes of cases, however, that will not yield to this treatment alone. One class is characterized by a tough, thickened, hypertrophic condition of the superficial layers of the scalp, produced, in my cases, by the constant irritation of the treatment just referred to, which has, nevertheless, not cured the disease. Those parts affected by the disease are seen elevated above the surrounding scalp. On these liquor potassæ inflicts little if any pain. It is in such cases that I have found salicylic acid very useful. A very convenient formula for its use is that commonly employed for corns:

- B. Acid salicyl.....3j;
Ext. cannabis Ind.....gr. xx;
Collodii. q. s. ad.....f. ʒj.
M.

This should be painted on for three days, then an effort made to tear it off. If this is successful, a tenacious strip comes away, on the undersurface of which are adherent a number of whitish, diseased hairs, full of the trycophyton—it epilates, in other words, as well as softens, the superficial layers of the scalp.

I have also used the salicylic acid with ether, instead of collodion, but it is not as effective. If the solution is not stronger than forty grains to the ounce, the cannabis Indica may be left out, which is in some respects an advantage, as green spots on a child's head do not enhance its beauty. Salicylic acid may also be used in the form of an ointment, an excellent formula for which was suggested to me by Dr. James Simpson:

R.	Acid. salicyl.....	3j;
	Sulph. precip.....	3ss;
	Bals. Peruv.....	f3j;
	Adipis.....	3j.

M.

Having made the scalp sufficiently tender and absorbent by the salicylic acid, the first solutions may be again used, or an ointment, alternating the treatment as local conditions indicate.

I have also used chrysarobin, but without success, though the trial was not sufficiently thorough to enable me to express an opinion as to its actual value.

Another class of cases that resists Mr. Harrison's treatment is characterized by small, circumscribed, non-elevated, uninfflammatory patches, varying in size from a small pea to a three-cent piece. There may be several of these scattered over the scalp. In one case in particular the hairs, were unusually firm and embedded much more deeply in the scalp than is ordinarily the case. Here the solid stick of nitrate of silver has given the best results. It is best applied in this way: Having rubbed the patch with the moistened stick, allow the patient to go without treatment for several days; then tear the black crust from the scalp with a pair of flat forceps, apply a drop or two of four per cent. cocaine solution, and reapply the nitrate of silver. By persisting in this treatment, intermitting when local conditions demand it, the disease can be eradicated.

In yet another class, in which Mr. Harrison's treatment either fails or inflicts a degree of pain out of all proportion to the amount of benefit secured, I have found ointments answer best. Of these, the most effective is an ointment of the biniodide of mercury, ten or twelve grains to the ounce

of lanolin and olive oil or lard. It is very much better than the oleate of mercury. Care must be exercised not to make it too strong, or else a stinging, burning pain results, which grows worse rather than better, and is in this respect unlike the pain inflicted by the two solutions. Olive oil will, however, relieve the former pain when gently rubbed into the scalp.

The objection to all ointments is that to be effective they should be rubbed in thoroughly every day, and the head not washed oftener than once in two weeks. As a consequence, more time and patience are required in the treatment, the child's head is apt to look dirty, new spots are more difficult of detection, and pillow-cases and hats are soiled unless protected. These things could be endured if ointments were more efficient; but as a rule they are not. Still, in choosing whether to use an ointment or not, it must be remembered that there is great difference in the skins of people as to the readiness with which ointments are taken up. In some the skin absorbs it as a sponge does water; in others it cannot be made to take it up. If, for instance, a child suspected of showing syphilis did not improve with rapidity upon Mr. Harrison's treatment, and its skin absorbed ointments readily, I should expect the greatest benefit from the treatment by biniodide of mercury in lanolin. In one case presenting the above conditions, I had a most gratifying result. In this connection it may be stated that I never saw the slightest trace of ptyalism produced by either the solutions or biniodide ointment.

Some cases are met with in which there are a few diseased hairs scattered among a large number of healthy ones, like weeds in a field of tassel corn. Time and again the disease will be thought cured, only to show itself after a longer or shorter interval. In some of these cases, if the head be clean shaven, the disease cannot be detected. Epilation and the persistent thorough use of whatever germicide has been found by trial to give the best results, offers the best prospects of success.

By the use of the methods of treatment described above, I have been able, in the past year, to cure eighteen cases of ringworm of the scalp in the Infirmary of Girard College, none of the boys showing any sign of relapse for at least two months. Of the number remaining under treatment at the expiration of that time (12), four seemed almost cured, and all but two or three were markedly improved.

ANASARCA WITH RECOVERY.
WITH NOTES OF A CASE DUE
TO HEART TROUBLE.

BY JNO. A. STAMPS, M. D. WALLACEBURG, ARK.

Until within the past few years the family physician's diagnosis of "a bad case of dropsy," and especially if caused by "heart disease," sounded the death knell of the patient, and caused the poor unfortunate and his friends to relinquish all hopes of any amelioration of the unpleasant train of symptoms. During the past few years there have been important advances made concerning our knowledge of this disease, and instead of using merely empirical treatment, we try to determine the cause, and having discovered this to adopt a treatment founded upon scientific principles.

The causes of anasarca are numerous, for instance; anæmia, especially that form occurring in young girls—cholrosis, diseases affecting or involving the secreting structure of the kidneys, as Bright's disease, scarlet fever, etc.; morbid state of lungs, by which the circulation through the pulmonary vessels is impeded, as in the pressure of morbid growths, etc.; and a very frequent and significant cause is heart disease, the result of inflammatory and other processes.

The cause of the dropsical effusion in my case was clearly traceable to heart disease or disturbance.

As this form is generally produced by some process which renders the heart incapable of performing its office of receiving the blood from and propelling it to every part of the body, and as a disturbance of the equalizing power of this organ would invariably lead to local congestions, we would expect these congestions and dropsies to show themselves first in the parts most dependent, or farthest from the driving force. Consequently among the earliest symptoms of the approach of this condition are a puffiness of the eyelids, œdema of the feet and hands, which as the disease progresses gradually becomes more extensive, until in all probability every tissue and organ of the body becomes more or less œdematous. The following case illustrates what I have said:—

Mrs. —, 34 years old, was married at 18, and has had 6 children. She enjoyed good health until 1878, when her 5th child was 2 weeks old, when she began to suffer with palpitation of the heart. This continued to annoy her at irregular intervals until 1884, when she discovered that her feet, ankles and eyelids were swollen. As she was then

in her 5th month of pregnancy, she paid no attention to this, thinking it would be all right when she was delivered. But one month after the birth of her child general dropsy developed and continued until I saw her, three months later. I found her feet, face and abdomen considerably bloated, she had shortness of breath which was especially marked when reclining, her liver and spleen were some what enlarged, her skin and conjunctiva were marked by jaundice. I gave her:

R Digitalis.....gtt. x
Potass. iodid.....gr. x
Tr. ferri chloridi.....gtt. x

every four hours in water, and in the course of two weeks succeeded in reducing the effusion to a minimum.

As soon as she had improved sufficiently she engaged in the performance of her household duties with the result of a speedy return of the anasarca, which proved to be more rebellious than ever.

She suffered much with dyspnœa and pains in her spine and limbs; she saw specks and a smoky film before her eyes. Upon examination I found her heart enlarged and there was a very audible, rather soft mitral systolic murmur. Her urine contained a considerable quantity of albumen. Her liver was enormously enlarged, reaching from the spine of the right ilium to the umbilicus, and was very much thickened.

On the 3d of April I was called and found her suffering with excruciating pain caused by suppression of urine. I introduced a catheter and found her bladder empty, and then ordered warm sitz baths and gave her 15 drops of tincture of digitalis and a drachm of jaborandi every three hours. In a short time her kidneys began acting profusely and the treatment was discontinued. On the next day there was a repetition of these symptoms, with the same treatment and the same results. The next morning I was called in haste, and found my patient semicomatose, with every symptom of uræmia. I had to act promptly, and decided that the eliminating action of the skin could be aroused sooner than that of either the bowels or kidneys, so I gave her 10 gr. doses of Dover's powder, watching the effects very closely. After two or three hours her condition improved, and I gave smaller doses of Dover's powder, with a dose of sulphate of magnesia, and digitalis and nitre. On the next morning she was much better, but still troubled with the anasarca. I now ordered citrate of potash and jalap, with iron, digitalis and iodide of potash. Under this

treatment all of the effusion disappeared, and I substituted for it iron, quinine and strychnine. After several light relapses she finally recovered and has enjoyed good health for the past two years, becoming pregnant the seventh time, and carrying the child to full term. I attended her in her labor, which was very difficult, requiring the administration of chloroform. Upon examining her heart, I was surprised to find no murmur whatever. She was fully under the influence of chloroform for 30 minutes. I never saw a heart behave better. She recovered from the effects of the labor quickly and without any serious complications or the least indication of a return of the anasarca.

LIGHTNING-STROKE FOLLOWED BY ACUTE BRIGHT'S DISEASE.

BY J. E. FREE, M. D., BENEZETTE, PA.

John O., a farmer, 35 years old, was putting his horses in his barn, when it was struck by lightning. He at once lost consciousness. When it was recovered, a few minutes after the accident, he found the horse on his right had been instantly killed, and the one on the left was struggling to regain its feet.

The barn was on fire, and the realization of his dangerous situation induced him to make an extra effort to escape into the open air. A short distance from the barn he met his wife coming to see if he was alive. She led him to the house, and then went back and managed in some way to put out the fire.

The living horse was not much the worse from its contact with the electric force, but seemed to be anxious to get away from the scene of the disaster. It was turned out to pasture, and soon recovered entirely. The dead horse was as soft as jelly, partly owing to the fact that every large bone in its body was comminuted. A short time after the accident the man was able to converse intelligibly, and stated that the last thing he remembered he was unbuckling the throat latch on the horse which was killed. Upon recovering consciousness, his attention was attracted by the struggles of the horse on his left. He was not conscious of any appearance of lightning or noise of thunder.

His right arm, which was closest to the horse which was killed, was numb. Paralysis of sensation was complete, while the power of motion was retained. This condition was only noticed from the elbow to the finger tips. The left leg from the knee to ends of toes, presented the same phenomena. To relieve these symptoms the arm was rubbed

with "*Magic Oil*," and it was supposed that its effect was beneficial, because the surface in the course of an hour presented a hyperæmic appearance, and began to show signs of returning sensation. The leg was not treated at all, and it improved in the same way.

Three hours after the accident the writer arrived on the spot, and found the injured man standing at the front gate. His face was flushed, his eyes congested, and altogether he appeared to be laboring under strong mental excitement. When he attempted to walk to the house, his left foot dragged like an ataxic patient's. The effort necessary to get from the gate to the door caused a mild choreic spasm, which subsided as soon as he sat down. He said he was sleepy, but had been advised not to lie down. As soon as possible he was put to bed, and a weak sedative solution administered, more to satisfy his mind than for any expected therapeutic effect.

The pulse was 100; temperature, 102°; respiration, 23.

No pain was complained of.

If it had not been for two ideas which were not altogether irrelevant to the occasion, he would have soon passed into a sound sleep. The dead horse was one he had been working on trial with the intention of buying, and his conscience was much exercised on the subject of the responsibility for the damage. The other source of disquietude was in regard to an accident insurance policy. He wanted to know if the company would pay him for loss of time if he should become disabled after having been able to walk. With much persuasion he was finally quieted enough to go to sleep.

On the following morning the patient was stiff and sore, and said he felt as if he had been beaten all over. The numbness in the arm and leg had somewhat abated, and he was able to get about the house without aid. A severe headache supervened during the day, and persisted for several days, when the characteristic symptoms of acute interstitial nephritis developed. At present, about one month from the time of the accident, he is rapidly improving.

—The London *Lancet* defines "moderate drinking" as that which is indulged in to the extent that the individual has a clean tongue, a good appetite, a slow pulse, a cool skin, a clear head, a steady hand, good walking power, and light, refreshing sleep.

PETECHIÆ AFTER PNEUMONIA —
REPORT OF A CASE IN PRIVATE PRACTICE.

BY A. A. NEFE, M.D., OF WHETSTONE, OHIO.

On Jan. 12, 1887, I was called in to see Ord. H., aged four and a half years, son of a farmer in good circumstances. Family history: Father rheumatic; mother healthy, but has two or three small lipomata. No *specific* history on either side. Boy has good food and water, and lives in a healthy locality. On examination I found pneumonia of right lung, which progressed so well that I discharged him Jan. 23rd. During the progress of the case there was delirium, and extreme nervousness, as manifested by screams and convulsive jerkings, when the patient was touched, or when there was the least noise in the room. I regarded the case as one of cerebral pneumonia. On Jan. 23rd I noticed ten or twelve spots. They were about the color of what is ordinarily termed a "blood blister," and they caused no discomfort, had no surrounding redness nor swelling, and as there were no indications of hemorrhagic diathesis, I paid but little attention to them, thinking they would disappear of their own accord. On Jan. 27th the father of the boy came to my office, saying his son was covered with the spots, which he termed "boils." They were larger, elevated and darker than before, and now caused considerable *itching*, but no pain. I gave him the following:

R. Tr. ferri chlor f ʒ j
Liq. pot. arsen. f ʒ j s
Aque q. s. ad. f ʒ j

M. Sig.—Half a teaspoonful *in water* after meals and at bed-time.

For the itching I gave the following:

R. Acid. carbolic..... grs. xx
Acid. tannic..... grs. x
Glycerinæ..... āā fl. ʒ j

M. Sig.—Apply on lint as needed, to relieve itching.

Jan. 29th his father requested me to go and see him, saying that while some of the spots were drying up, others seemed to be forming. The itching was relieved. On my arrival, I found the boy sitting up playing with his brother. He said his legs hurt him when he walked. His pulse was 92; his temperature 99.2° (Fahr. ;) his respiration 24. His appetite was voracious, and his bowels regular as to frequency, but the stools looked like a mixture of grumous blood intimately blended with mucus. Upon inquiry I found that the stools had presented this appearance

for two days, but as it began about the time of the prescribing of the iron mixture the family thought its appearance was owing to the medicine. That it was not, is shown by the fact that it disappeared during the continuance of the iron.

I will now attempt to describe the spots, though they should be seen to be appreciated. They varied in size and color according to location. Those on the face, scalp, trunk, and in the mouth, were about one line in diameter but not elevated. They were of a dark-red color, if of more than twenty-four hours duration, more recent ones being paler. Those on the extensor surfaces of the limbs, especially on the forearms and legs, were about four lines in diameter, and about two and a half lines high, above the surrounding surfaces. The large ones were of the color of venous blood, afterward getting darker. Upon cutting into two of the larger spots there oozed from the more recent ones a little bloody serum. The other peeled off in layers like the coats of an onion, finally disclosing a small coagulum, dry and dark. These large ones, in form, resembled half a filbert placed with its cut surface on the skin. There must have been at least fifty on the head and face, while on his entire person there were fully three hundred. The patient said the cutting caused no pain, but tickled his leg.

The treatment already mentioned was continued, and in about a week new spots ceased to appear, but those already formed still remained. To-day (June 30th) the boy is enjoying good health. The spots, though not so prominent, are still there, and of a darker color, except those on his head and face, where there is only a pink stain, remaining to show their former site. Those in his mouth have entirely disappeared.

In conversation with a number of physicians I have found but one, Dr. Ridgeway, of Galvin, Ohio, who has seen such a case. Neither do I remember having seen such a case recorded. In Dr. Ridgeway's case, the administration of tr. ferri chlor, sufficed to limit the occurrence of the spots, as it did in my own, but they had not entirely disappeared in a year from their occurrence.

Thinking the case worth recording, I have given its main features as nearly as I can. I would like to see such cases written upon, so that we may know what has been tried and with what success.

A tooth immersed in a solution of the tincture of iron in eight parts of water has its enamel entirely destroyed in one hour.

HOSPITAL NOTES.

MEDICAL DISPENSARY OF THE UNIVERSITY OF PENNSYLVANIA.

Reported by M. HOWARD FUSSELL, M. D.

Acute Nephritis.—Phthisis Pulmonalis.

Thomas W., laborer, aged 19. Mother and aunt dead of phthisis.

Shortly after his mother's death, the patient came to the dispensary complaining of nervousness. He would awake in the middle of the night and be forced to get up and dress. There could be nothing found to account for this, save probably fear, which he expressed, that he was going to die like his mother. The man's physical condition, to all appearances, was excellent. He made two or three visits to the dispensary, and was lost sight of for almost a year.

In August, 1885, he returned with the following history: Has been very nervous since last visit. Four weeks ago, after working in the quarry all day, was attacked with stiffness and soreness across loins; had no chill; has *never had any œdema*. Urinates five or six times daily. After each act of urination passes a few drops of blood. He sweats at night; his appetite and strength are failing; has a slight cough.

On examination his temperature was 102°. A urethral stricture, tender, was found one inch from meatus. Examination of the chest negative. Fingers clubbed.

Urine, examined the day after first visit, was found to contain an abundance of albumin, blood, blood-casts, and dark granular casts.

Visits were made at intervals of two days. At each visit the temperature was found above normal, and the urine still contained blood and casts. One week after first visit increased fremitus; slightly prolonged expirations were noted at left apex. On the 26th of August there were evident signs of consolidation of left apex.

The case was again lost sight of until October 16th (had been "doctoring with Kickapoo Indians"). Softening was evidently taking place in the diseased lung. Patient was anæmic, wasted, sweats, has hectic, no appetite, is unable to work. Urine still bloody and contains casts. Has had no œdema.

December 4th. Is failing rapidly. Small cavity at apex. For the first time he has been persuaded to bring sputum, which contains myriads of tubercle bacilli and much elastic tissue. The urine still contains casts.

After this the case ran a rapid course. In February, 1886, I was called to see him at home. He was suffering greatly. A pyopneumothorax had developed, and the patient died. A post mortem was unfortunately denied.

I am led to report this case from the curious association of acute inflammation of the kidneys with phthisis pulmonalis. From the history and examination of the case, it would appear that the inflammation of the kidneys began at least five weeks before there were any physical signs in the lungs. In all probability the renal trouble was tubercular in nature, and the entire malady, disease of lungs and kidneys, was the result of a general outbreak of tuberculosis. The lung signs were delayed because of the greater difficulty of demonstrating the disease in the chest. The treatment was unsatisfactory, not only because of the virulence of the disease, but because of the irregularity of attendance of the patient.

INFIRMARY FOR NERVOUS DISEASES.

CLINIC OF PROFESSOR OSLER.

Reported by DR. C. W. BURR, Resident Physician.

Case of Supra-orbital Neuralgia in Chlorosis—Cure with Blaud's Iron Pills.

This case illustrates two points: The occurrence of severe neuralgia in chlorosis and the rapid improvement in blood-condition, with cure of the neuralgia, by the use of Blaud's pills. The patient is a girl, seventeen years old, well-built, without any history of malaria. She has been very pale since last October, and is now (May 18, 1887) extremely chlorotic. She feels weary, sleepy, and has severe neuralgia. The pain is chiefly in the right forehead, over the eye; sometimes over both brows. The attacks come on about nine A. M., and last two or three hours. She has not had a free week for many months. The face flushes, and on several occasions she has vomited during an attack. Menstruation is not very regular, but is painless, and the flow is scanty. She is short of breath on exertion. She has tried many remedies for the neuralgia, without effect. Hæmic murmur at the base of the heart. Hæmoglobin, estimated with Fleischl's apparatus, at 37 per cent. Ordered Blaud's pills, three to be taken, three times a day.

May 25th—Patient has had no neuralgia for three days, and looks and feels better.

June 1st—No return of neuralgia. Patient

looks remarkably well. Color good. Is not so short of breath.

June 8th—Patent continues well. Does not look like the same girl. Hæmoglobin 80 per cent. Ordered to continue the nine pills daily for another week.

June 15th—Is practically cured. Says she has not felt so well for more than a year. Pills reduced to three daily.

REPORTS OF SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, June 22, 1887.

H. AUGUSTUS WILSON, M.D., IN THE CHAIR.

DR. J. M. BALDY, read a paper entitled
The Relation of Pyosalpinx to Puerperal Fever.

Until within a few years the term "Puerperal Fever" has been applied to certain conditions of the parturient woman without conveying any very definite idea as to the exact pathological lesion involved. As in microscopy we designate everything that we are unable to recognize by the general term "molecular debris," so in the parturient woman we have been in the habit of applying the meaningless term "Puerperal Fever" to a set of symptoms, the origin and source of which we knew not. As usual in such a condition of ignorance, an innumerable number of theories sprang up on the subject—the most widely accepted of which was probably that advocated by Fordyce Barker, viz., that it is a specific febrile disease.

Thanks to the zeal of bacteriologists, we can state without hesitation that the disease is of undoubted septic origin. I have no intention of entering into an exhaustive discussion of puerperal septicæmia, but shall try to add something to our knowledge of the particular subdivision which may be called puerperal pyosalpinx.

The belief that some puerperal fever cases are cases of septic salpingitis is by no means new. Martin, in a recent investigation, found the microorganisms of puerperal septicæmia in seventy out of two hundred and eighty-seven cases of inflammation of the tubes.

Schræder held that septic endometritis of the uterus did not extend to the tubes, *as a rule*; but he qualified this opinion by following it up closely with the remark that *occa-*

sionally the endometritis did go on to a purulent salpingitis. Säger has recently stated "that salpingitis septica, coexisting with severe puerperal septicæmia has never as yet given the surgeon an opportunity to remove the principal focus of disease by extirpation of the tubes. It is possible, however, that under certain circumstances such a procedure might be indicated." Even before these words of Säger's were in print the opportunity to remove the principal focus, and, I may say, in this case the only focus, of disease, *had* occurred and had been taken advantage of by the surgeon, as witness the following case:

M. P., 23 years old, was delivered of a male child after a tedious but normal labor, some four years ago. She made a good recovery, and has never suffered from a pain or ache in her abdomen since—she has, in fact, considered herself a typically healthy woman. On February 3d, last, I was called to attend her in her second labor, and found a dead child, with the placenta and membranes, lying between her thighs. Her bare arms, chest, and legs were exposed in a room without a fire. On the second or third day she had a chill, a rise of pulse and temperature, tympanitic and tender abdomen. These symptoms abated somewhat, and I lost sight of her for several weeks. One month from the date of her confinement, I was again summoned and found that she had been suffering ever since I had last seen her; this time she was so emaciated that I hardly recognized her. Her temperature was over 102°, her pulse over 130; she was having chills and creeps, hectic, night sweats, and sleepless nights; her abdomen was swollen and tympanitic, and intensely painful; her bowels were loose and her stools fetid; micturition and defecation were both painful—she was evidently fast approaching death. An examination of the soft parts showed no signs of a recent tear; the uterus was subinvolved, and on the left side there was a large boggy mass, firmly adherent, tortuous, and extremely tender. The right side was tender, but no tumor could be detected. Abdominal section was advised as the only hope of saving life, and the proposition was eagerly accepted by both the patient and her friends.

Dr. Joseph Price saw the case with me and confirmed my opinion of immediate operation. I operated on the fifth of March (the delay being necessary in order to have her surroundings cleansed); Dr. Price, of Philadelphia, Dr. McMurtrie, of Danville, Ky., and Mr. Eckman, of Scranton, Pa., being present and assisting. The right tube and ovary were found healthy and were not removed. The left tube was found almost as large as the uterus and firmly adherent in all directions, especially to the bowel, from which it was separated with the utmost difficulty. An abscess of the cellular tissue was ruptured while breaking up the adhesions, and pus welled up through the abdominal incision. Both tube and ovary were removed. A large cheesy mass on the bowel at the point of adhesion was trimmed down with scissors and an application of Monsel's solution made to the bleeding points. After a free irrigation a drainage tube was put in and the incision, which was only one and a half inches in length, was closed with three deep silk sutures.

On examination the tube was found to be distended with pus; the ovary was broken down and contained

pus. The patient rallied quickly from the ether, and had no shock. Her pulse fell to 80 and her temperature to almost normal within twelve hours, and remained so until about the seventh day, when the drainage tube was removed. Up to this time she had done as well as possible. There had been little or no pain, no catheter, bowels opened naturally; no drugs of any kind had been administered. The day after removal of the tube her pulse began to rise, as also did her temperature; pain developed in her left ovarian region, and she began to have hectic and cold creeps. About the eleventh day there was a free gush of pus from the tube tract and she began to improve again from that moment. A rubber tube was inserted and passed deep into the pelvis and the abscess was washed out twice daily. The discharge gradually diminished and the tube was again removed. The wound is now completely healed and the patient is a well woman.

That these cases exist much more frequently than we have any idea is certain, and that oftentimes a life, otherwise doomed, can be saved by operative interference is but a natural conclusion. Mr. Tait mentions four deaths from this cause in Queen Charlotte's Hospital, as verified by post-mortem examinations, and says that "these cases during life were all regarded as puerperal fever." Sanger comes forward with two cases which have come to his knowledge in which the over-distended tubes burst and discharged pus into the abdominal cavity, with death on the fourth day after confinement in one case, and on the twenty-first day in the second case. Who can doubt that, in the light of our present surgical knowledge, if these cases had been recognized and operated on, the women would have all survived? The day has passed, I hope, in which we will allow a woman to die of pus in her abdomen without at least proposing an abdominal section, not merely as a last resort, but as an early means of relief and safety. It is by no means to be held that because a parturient woman has an inflammation of her tubes, she is to be rashly submitted to the knife of the surgeon. I have, within the past few months, seen a woman who presented an elevated temperature, with anorexia, restless nights, and other general symptoms, and whose tubes, on examination, I found enlarged and painful. Under careful treatment this local trouble all subsided, and with it the general symptoms disappeared and the patient made a satisfactory recovery. These mild cases, however, often go on to a chronic condition, when unrecognized and neglected, and the woman eventually falls into the surgeon's hands to be relieved of a pus-tube, and then generally gets the credit of having had a gonorrhoea at some period of her life, or else drags out a miserable existence until she dies of her trouble, or some other disease puts an end to

her suffering. The following case fairly illustrates this:

Maggie F., thirty-one years old, married thirteen years, has had one miscarriage and five children. Had always had good health until her last confinement, six or seven years ago. At this time she had a slow and tedious "get up." Her physician told her that she had "an inflammation in her stomach." She was confined to bed for several months. She has never been well since that time; has been constantly losing flesh, suffered from pain, and has generally felt wretched, not able to work half the time. I was called to attend her on the 31st of March last, and found her suffering with peritonitis, of which she had been getting gradually worse for the past three or four weeks. An examination disclosed a pyosalpinx firmly bound down and extremely tender. I made an abdominal incision and removed a large and densely adherent tube and ovary, both filled with pus, from the right side. Recovery was uninterrupted, and she has been relieved not only from her peritonitis but from all her old sufferings. The last time I saw her she told me she was feeling more and more like herself, and was fast regaining her former weight.

The only regret I have in either of these cases is that I did not remove both appendages. The case M. P., has recently had an inflammatory attack in the remaining tube, from which she has recovered, but I am afraid the time will come when another operation will be required. I think where pus is found that both sides should be removed always, whether one-side is apparently healthy or not, the patient being willing, of course.

Whether or not this disease arises *de novo*, or, having already existed from other causes, has simply a new inflammation added by the puerperal condition, must be determined by careful investigation in each case. Hecker, as early as 1878, mentions two cases in which an old pyosalpinx was lit up by the puerperal state, and Sanger adds another from his own practice in which the salpingitis had a prior existence. In the case of M. P., the patient was apparently perfectly well up to the time of her last confinement, but the adhesions were of such a firm character that it is safe to presume that there was an old inflammatory trouble prior to this time. It is impossible to imagine the formation of such organized bands in so short a space of time. At her first confinement she had "an inflammation in the stomach" and that was the probable beginning of her trouble. She undoubtedly has had tubal disease ever since (probably pyosalpinx) and has not suffered enough inconvenience from it to seek advice. This is often the history of these women; they complain of pain and general ill-health, loss of flesh, anorexia, and sleepless nights, etc.,

but oftentimes they do not even suspect the real origin of all their trouble. The result in the case of this particular patient is a valuable lesson of the dangers of such a neglect, and is an additional reason why the diseased structures should always be removed when recognized.

Of course, the possible contagion of gonorrhoea can never be eliminated excepting by a microscopical examination. In both my cases, although the trouble seemed very clearly to have arisen at the time of confinement, yet the chances of gonorrhoeal infection both before and after pregnancy are not to be denied; however, in lieu of a microscopical examination, the chances are all in favor of a purely puerperal origin. But whatever the source, the results are the same, and it is only by prompt measures we may hope to save some of these cases. It is no longer surprising that even under the most careful antiseptic treatment of the uterus, vagina, and person of the patient, as well as the person of the attendants, that still patients are lost from septic poison.

This disease has been recognized and operated on at least four times in Philadelphia; one case was operated on just two weeks previous to mine, by Dr. Longaker, in which a pyo-salpinx was removed, the patient dying on the second day. I may state here that this operation was delayed three or four days after an abdominal section had been urged. Dr. Joseph Price has since operated twice, and in one case found more than a quart of pus in the abdominal cavity; the case, unfortunately, came into his hands too late and the patient survived only two days.

These cases, though few in number, certainly teach us that the work done in this direction is encouraging, and although a large percentage of the patients have died, it only warns us of the extreme importance of an early diagnosis and prompt surgical interference. It becomes our imperative duty in every case of post-*puerperal* trouble to make a thorough investigation on the appearance of the first symptoms, and should a fulness be found on either or both sides of the uterus, accompanied with pain on touch and with constitutional symptoms of gravity, there should be no hesitation as to the course to pursue. This being secured, our present high mortality of one woman out of every hundred delivered in large cities, as recently stated in a statistical paper on lying-in charities in the United States, must be very largely diminished and the fatal results now surrounding our parturient women must become infinitely less.

DR. B. F. BAER exhibited a fibroid tumor of the uterus, and made some remarks relative to

Hemorrhage at the Menopause.

This tumor was removed yesterday from a woman forty-two years old. About a year ago she began to lose more than the normal amount at her periods. Soon after, she suffered from attacks of metrorrhagia twice a month, sometimes almost to syncope. At times she would flow continuously for two weeks. Finally, in the intervals, she began to have a fetid, watery discharge. She was pale, emaciated, and cachectic.

Now, such a history often indicates the presence of cancer, but not always. It *never* means that the woman is simply near the menopause. A great deal of harm has been caused by that idea. In this case the physician thought that the hemorrhage was due to the menopause, and did not consider it necessary to make an examination. But finally the patient insisted upon it, in order to find out if there were not a local cause. He then made the examination, and diagnosed the case correctly. I saw the case in consultation, and removed this fibroid tumor, which is ulcerated at the base, and hence its fetid discharge.

I have known many instances where patients have been put off by the statement that the hemorrhage was due to the change of life, and almost bled to death from a pathological cause. Several years ago I reported a marked case of this kind, which was easily cured by the removal of a small polypus from the neck of the womb.¹ At first the hemorrhage was said to be menopausal. After a time the patient became cachectic, and the case was pronounced to be one of cancer. As cancer is properly regarded as incurable, it was considered unnecessary to submit the patient to an examination. This patient was cured by the removal of a fibroid polypus! I have actually known a patient to die from repeated hemorrhages caused by a benign disease, where the bleeding was at first attributed to the menopause, and, finally, to cancer. I believe that great harm is often done by physicians putting patients off with the statement that the hemorrhage at this period of life is the result of the change of life, instead of seeking for the real cause.

DR. G. B. DUNMIRE referred to the case of a patient who nearly lost her life because of his reluctance to examine unmarried women. The examination was put off until

¹ The Significance of Metrorrhagia, etc. Amer. Journ. of Obstetrics, Vol. xvii. No. 5, 1884.

he was compelled to make it, because of the frequent and continuous menorrhagic attacks and the anæmic condition of the patient. He found a small vascular polypus, which was removed, and the patient recovered.

Cirrhotic and Cystic Ovaries.

DR. J. M. BALDY exhibited some specimens of cirrhotic and cystic ovaries, removed from Mrs. S., under the care of Dr. Wolfe, of Skippack, Pa. The patient married four years ago, at which time she was in perfect health. Shortly after marriage she had a miscarriage; since then there have been several. Since the first miscarriage, she has suffered pain constantly, and the menses have been profuse. Dr. Wolfe recognized a tender mass posterior to the uterus. Dr. Baldy found a prolapsed ovary, enlarged, adherent, and very tender. The patient bled for three days after the examination, and suffered great pain, as she had always done before under examination. Dr. Baldy removed both ovaries last Thursday. Since the operation, the patient has been doing well. On the sixth day her temperature was 99.8°, and her pulse 72.

CHICAGO MEDICAL SOCIETY.

Stated Meeting, May 2, 1887.

THE PRESIDENT, W. T. BELFIELD, M.D., IN
THE CHAIR.

DR. CHARLES T. PARKES reported two cases of

Excision of Cervical Glands.

One was in a child five years of age; the other in a child of twelve. In the first case the mass was on the right side, the glands extending from the ear to the clavicle, there was no portion of the neck unoccupied by more or less of these glands. In the boy of twelve it was even worse, as the photograph shows, the glands extended beyond the midline of the neck posteriorly. The trachea was carried two inches to the right of the midline by these tumors. They interfered with inspiration, and failing to influence them by medical treatment they were subjected to operation and the glands all removed. I have seventy-five of these glands which were removed from the boy of twelve years. As far as the removal of the cervical gland is concerned, it is a very simple operation to remove one gland if it is superficially situated, but when the deeper layer of glands are implicated, glands that are as extensive as these were, it makes a formidable

operation. In the latter operation there was not a blood vessel or a nerve in the neck below the parotid gland that could not be seen. It was a very extensive operation, the most formidable that I ever attempted to do in anything of this kind. The child lost a good deal of blood, notwithstanding the greatest of care. In both cases, after the first incision, the knife was laid aside and not used at all unless necessary. The incision was made over the most prominent part of the tumor and the mass laid open to view at once; subsequently the tumors were removed by scissors, keeping close to the growth. It is a very easy thing to remove a superficial tumor, but it is difficult to safely remove these deeper tumors as they lie along the deeper vessels and in no instance should any tension be made on the tumor. The capsule should be exposed to view and the tumor picked out of its bed slowly. Dr. Van Buren, in his "Surgery," in the chapter on hemorrhage, gives a graphic description of the terrors a young man got into by pulling upon one of these tumors and touching the knife to it while tense. The first case I operated upon early in March; the boy recovered without any difficulty whatever.

DR. CHRISTIAN FENGERS said: In connection with the extirpation of glands of the neck I wish to make a few remarks and show a patient. It is not exactly because this is a case of the same character as Dr. Parkes's but it is more to point out the limits of the possibility of operation on the neck. This case is one of

Secondary Carcinoma from Cancer of the Lower Lip,

which was removed in December, 1884. In April, 1885, the patient came to me with enlarged glands on both sides of the neck and no relapse *in loco*, consequently no tumor on the lip. Those glands were removed on both sides in the carotid triangle. On the right side there was invasion of the facial vein with a thrombus about half an inch long; consequently that vein was ligated below the thrombus, between the thrombus and the jugular, before removing the tumor. The invasion of a vein by any of the malignant tumors is a very grave complication, as we always expect a relapse. In May, 1886, there was a tumor felt on the right side, the same side on which the facial vein had been invaded. This tumor was about the size of a walnut when I removed it. It had invaded the jugular vein so that an inch and a half to two inches of the jugular vein was re-

moved. It is natural that I should consider the case to be a hopeless one, as far as relapse is concerned, even after primary healing of the wounds; but to my astonishment, the patient is well and there is no relapse anywhere. The neck is everywhere perfectly free, and it is one year since the last operation. Before the beginning of the second year after an operation for carcinoma most of them have relapsed; according to the statistics of von Winiwarter, 82 per cent. relapse within the first quarter of the year, the relapses getting very rare in the second year. Thus, when there is no relapse at the end of one year, we commence to consider the patient safe. When we have to deal with malignant tumors in the neck there is a certain limit to operating which we cannot very well pass over.

I will show a photograph of another case which represents the other side of the limit. It was a carcinoma, not secondary but primary, in the lymph glands of the carotid triangle, or perhaps an alveolar sarcoma; I was not able to make a diagnosis. The tumor was in the carotid region and was about the size of an orange, somewhat movable from side to side, and not from above downwards. In these tumors there is a certain amount of immobility that will decide the surgeon beforehand to decline operating. But the amount of immobility is somewhat disputed, as König and Friedel and others who have written monographs on operations in the neck, state that, even if we have a tumor that feels rather immobile, we find that when we get down more and more, the tumor that seemed immovable from the beginning, gets more movable and finally can be got out. In the extirpation of this tumor not only the jugular vein was invaded (it was ligated double and removed) but the sheath of the common carotid artery was invaded. There was no carcinomatous tissue, however, in the wall of the artery itself. You will remember that the artery has a sheath separate from the common sheath, around the artery and the vein. The artery was laid bare to the extent of over an inch on its outward surface. The patient had on the third day a slight hemorrhage, which was not reported, as it was thought it was unimportant, and five or six hours afterwards he had a final hemorrhage which took only about a minute. The microscopic examination of the wall of the carotid showed that there was no invasion of carcinoma tissue, but near to the place where the tumor had invaded the sheath there was an island of granulation tissue in the intima, and this was

the place where the artery ruptured. As to the limits of a possibility of operating, I should put it where the malignant tumor has passed through the vein (which we can always remove with safety providing we keep our wounds aseptic) and into the sheath of the artery. Here we meet with the danger of secondary hemorrhage, and have to resort to ligature of the common carotid, which in itself is a dangerous operation.

DR. C. T. PARKES: It has been said with reference to these cervical glands, by a surgeon of good reputation, that it is always proper to do a surgical operation on them, because if you take out a few of the big ones the little ones get frightened and go away. That has not been my experience. Unless you get out all of the chain of glands that are implicated, the smaller ones are sure to enlarge rapidly soon after the operation. I have several cases in my notebook, one an old man on whom I operated about six months ago. The tumor was of immense size. It was sarcomatous, and among other tissues the glosso-pharyngeal nerve was divided, the dygasticus muscle was torn off, and the lower half of the parotid gland removed under the supposition that it was a part of the tumor, and the facial nerve partly divided. That man recovered. It is not an unusual thing for a patient to recover from these operations on tumors in the neck. It is my belief that a surgeon is not justified in operating on any of them where it is a malignant growth, or of such degree of malignancy that all the tissues are implicated in it, or where the mass is fixed and immovable; because the patient will die either from the operation or the action of the disease. If the attachments of the tumor can be pretty well defined, although immovable, certainly if free and incapsulated, it makes very little difference, because the records show that nearly all the important tissues of the neck have been divided in these operations, sections of veins, arteries and nerves made, without death following. The cases related were merely instances of cervical glands.

—Lightning plays strange freaks sometimes. It knocked a passenger off the platform of a moving car near Tremont, Pa., this summer, and he fell under the wheels and was fatally injured. In Tennessee three ministers and six other persons, attending a funeral, took shelter under a tree, and all were killed; and a whole party of negroes recently shared a similar fate.

PERISCOPE.

Cocaine Anæsthesia.

Dr. Franz Fux, of Laibach, in an article on this subject, published in *Memorabilien*, May 10th, 1887, says:—

Among the advantages of a local anæsthetic may be mentioned: Its entire freedom from danger to the life of the patient, although this danger has now happily been reduced to the minimum in etherization. This is especially true in regard to operations about the respiratory tract, as in tracheotomy. Again, a local anæsthetic can be administered without an assistant. This is of great importance to the country practitioner, who finds it often difficult or impossible to get the required number of skilled assistants to properly give the anæsthetic. So much has been written about the account of the introduction of cocaine that it is not necessary to review all the facts. Schroff, in 1862, first called attention to the astonishing effect of this drug. As soon as Prof. Wolfner made known the anæsthetic power of injections, a great number of ways in which it was used successfully appeared in the medical journals.

The best way to apply cocaine for surgical purposes is as follows: Hydrochlorate of cocaine should be used, as cocaine itself is very insoluble, and the other preparations do not possess the same properties. Even if the drug be dissolved in twice distilled water, the solution soon becomes turbid. This can be avoided by the addition of a little glycerine or of the bichloride of mercury. But the hydrochlorate is so soluble in water that no time is lost in preparing a fresh solution for each operation. There has been much discussion as to the strength of the solution to be used, and the number of points at which the solution should be introduced. Not less than three-quarters of a grain, nor over a grain and a half, should be used. If more than this be used, cocaine intoxication may be produced. This can, however, be readily removed by the use of nitrite of amyl. From four to six injections may be made, rather than to use a weaker solution, and make more injections. The injections should be made with a hypodermic syringe, and in a circle around the part to be operated upon, and they should go in underneath as far as possible. The syringe should be withdrawn gradually, and the last drop emptied as it nears the skin. It is well to wait from eight to ten minutes after the injection before beginning an operation. Anæsthesia produced

in this way lasts from fifteen to twenty minutes, but this period may be prolonged by keeping the part moist with sponges soaked in a cocaine solution.

Cocaine suppositories are useful in spasm of the sphincter ani, and a five per cent. solution may be injected into the bladder before making an examination of this viscus, or in cases of painful vesical catarrh.

Deglutition of Air.

DR. S. K. WILLIAMS, of Foster, Mo., says, in the *Kansas City Med. Record*, July, 1887:

During the years 1880 to 1883 I was frequently called to see a boy some thirteen years old, (when first seen) who had contracted a habit, denominated by his parents, "wind sucking." His custom was to steal away to some secluded spot, then "lying down in a sort of curled up position," viz.: the knees drawn well up to the abdomen, the head inclining forward, and placing a piece of stick or pencil between his teeth, he proceeded to fill himself with air. This he succeeded in doing to a very alarming extent. The stomach would be distended enormously, and pain would be so severe that the services of a physician were usually required. The habit seemed to be a fascinating one, and would be resorted to very frequently, unless he was kept under guard. He was never known to attempt the "filling process" when he knew he was observed.

The habit, or disease, began at the age of eleven, and death took place at about fourteen, during the time he was under my care. Relief was promptly afforded by introducing a tube into the stomach, or when nothing of this kind was at hand, by giving an emetic, and making strong and continued pressure over the stomach during the emesis.

The Use of Santonin.

White santonin is more poisonous than that which has become yellow through exposure to sunlight, though the latter does not show any diminution in its therapeutic properties. The dose for a child of less than two years should not exceed three-fourths of a grain. In all cases it should be associated with a purgative—calomel, for example—to facilitate its elimination. Santonin is innocuous or toxic, in proportion to the rapidity with which it may be eliminated, and this varies in individuals. Lewin and Caspar recommend that it be administered in solution with oil. In this form it is absorbed by the intestines slowly enough to permit a direct and prolonged contact with the worms.—*Journal of Pharmacy*, June, 1887.

Antifebrin, the New Antipyretic.

Dr. Ernst Heusler, in a short and practical article in the *Indiana Medical Journal*, July, 1887, says:—

Antifebrin is a white, neutral, crystalline powder, inodorless, of a slightly pungent taste, readily soluble in alcohol and alcoholic fluids, as for instance in wine, but almost insoluble in cold water; more soluble in hot water. It is a chemical body, which had been known for a long time; but its value as an antipyretic was discovered, not long ago, by Dr. A. Cahn and Dr. P. Hepp, and experimented on in the medical clinic of Prof. Kussmaul, of Strasburg. Its chemical name is acetanilide or phenyl-acetamide, and its formula is $C_6H_5NHC_2H_3O$.

Antifebrin possesses remarkable power in controlling abnormally high temperatures, but does not affect the temperature of healthy persons. Four grains of antifebrin corresponds to fifteen grains of antipyrin, so that in spite of its slight solubility, the new drug acts quite as quickly, and four times more powerfully than antipyrin. With the lowering of the temperature there is also a decrease in the frequency of the pulse, but an increase in volume. It never makes any nausea like antipyrin, and the diaphoresis is moderate in quantity.

Drs. Cahn and Hepp made clinical observations on about one hundred patients in cases of typhoid fever, erysipelas, acute rheumatism, pulmonary phthisis, abscess of the lung, pyrexia in leukemia, pyemia in consequence of cystitis and bedsores, septicemia, and pneumonia migrans.

The effect of four grains of antifebrin is manifest after an hour, and the lower temperature remains, as a rule, from six to eight hours. When the temperature rises again, shivering has not yet been observed to take place, as it does after the use of antipyrin and kairin.

Besides the great advantage of the success of small doses, the absence of troublesome symptoms connected with the stomach, and the relatively small perspiration which ensues, antifebrin is extraordinarily cheap.

I have tried antifebrin in cases of typhoid fever, pneumonia, and pleuritis with very good results. The duration of illness seems not to be shortened, but the lowering of the temperature is surprising.

The febrifuges which were known up to the present time were either phenols (carbolic acids, hydrochinon, resorcin, salicylic acid), or they were bases, and belonged to the chinolin group (chinolin, kairin, antipyrin,

thallin, quinine); but here, for the first time, we have an indifferent body, which differs very much in its composition from the above-mentioned substances.

Antifebrin can be obtained from any first-class chemist, and costs only twenty-five cents an ounce.

Broncho-Pneumonia due to Nematoid Worms.

Dr. J. C. Carrico records, in the *Maryland Medical Journal*, the following case of a child, aged three, who was just recovering from an attack of whooping-cough, and on the previous days complained of chilliness, which was soon followed by fever and much difficulty in breathing:

Upon seeing the little one I observed the breathing to be very rapid, superficial, and labored; respiration 52, pulse 140, temperature 103.4° , and cyanosis extending over the entire face. On auscultation *râles* were found abundant over the chest; but the examination was not satisfactory, owing to the excessive dyspnoea and fretfulness of the child.

From the previous history of whooping-cough, and the initial symptoms of the attack, as well as the sensible signs, broncho-pneumonia was promptly diagnosed, and an emetic exhibited with the most happy results.

The vomiting brought up a full-grown worm, nine inches long, and from that time on recovery took place uninterruptedly.

Removal of the Placenta.

Lasarewitsch, in his clinic and private practice, uses the following method of removing the placenta and membranes.

He waits twenty minutes for their spontaneous expulsion. He then rubs the abdomen over the fundus of the uterus. If the uterus lies in its normal position, that is, in a direct line with the outlet of the pelvis, he slowly and gently pulls on the cord, *without twisting it*, while the nurse holds the uterus in a correct position.

If the uterus has fallen to one side (which happens in his experience in two-thirds of all the cases), and forms an angle with the internal os, he then runs his hand along the lower part of the abdomen just above the symphysis pubis, and presses the uterus into its normal position, and holds it there while the nurse removes the placenta as above described.—*Memorabilien*, May 10, 1887.

Electricity in Gynecological Practice.

DR. ANDREW GRAYDON reports in the *Medical News*, June 25, 1887, a series of cases of retroflexion and antelexion of the uterus, and of chronic pelvic cellulitis much benefited by the systematic use of electricity.

The method of treatment is detailed under the individual cases. In sharp flexions he begins with a flexible electrode insulated to within two inches of the tip, and as soon as the curve of the uterus will allow, this is replaced by a stiff one, similar to a uterine sound, with the same insulation as the flexible one. This he is in the habit of connecting with the negative pole of the faradic machine. Although the choice of poles is *here* a matter of little importance, in galvanism it is. In the case of a retroflexion, the positive electrode is introduced into the bladder. If it be an antelexion, a flexible twisted wire electrode is placed in the rectum. This electrode is insulated up to the point, which is a movable olive, allowing graded sizes to be used. This form of electrode is also found of service in treating constipation, etc., as it will follow the convolution of the bowels with ease and little pain.

The electrodes should always be placed in position before turning on the current or connecting with the battery. In the beginning a painless current should be used, slowly increasing to the point of the patient's comfortable endurance. The current should be turned off gradually by means of the rheostat before removing the electrodes. Neglect of this will cause pain to the patient as the electrode passes over the perineum.

The conclusion Dr. Graydon draws from his work is, that in electricity we have a valuable agent. In uterine displacements, ill-developed ovaries and uterus with amenorrhœa, and in sub-involution, the faradic current may be used with advantage. But the galvanic is more valuable. All who do gynecological work know how stubborn many conditions are, and how slow to respond to remedial measures. Chronic ovaritis, pachysalpingitis, chronic peritonitis, cellulitis, lymphadenitis, and pelvic neuralgia, try the skill and patience of the physician. Electricity promotes absorption of the adventitious tissue, allays pain and irritation, and sets up reparative action. It is within the reach of all physicians, no very extended knowledge is required to be able to use it with safety and advantage; and, although it requires time in its application, the benefits it confers upon a class of patients, in which other treatment is either useless or harmful,

amply repay for any outlay of time and the little expense attending it.

Treatment of Consumption by Hypodermic Injections of Substances Dissolved in Vaseline.

The *Medical News* of June 25, 1887, gives a series of formulæ for the hypodermic use of substances dissolved in vaseline, as proposed by Meunier, of Lyons; which Meunier considers especially adapted to the treatment of pulmonary phthisis, and which he publishes in an article in the *Revue Générale de Clinique et de Therapeutique* for May 19, 1887:

1. Eucalyptol.....1 part.
Liquid pure vaseline.....4 parts.

This solution affects the bacilli but little, but lessens fever and secretion, especially in bronchorrhœa; in small doses it is a tonic.

Dose forty minims twice daily.

2. Phenol (carbolic acid) pure.....1 part.
Eucalyptol.....1 part.
Liquid pure vaseline.....18 parts.

Eucalyptol is employed to aid in dissolving the carbolic acid, which is sparingly soluble in vaseline.

This solution diminishes the number of bacilli, and replaces with advantage the preparations of creasote which disturb the stomach; it lessens fever.

Dose, one injection daily of eighty minims, or two of forty minims.

3. Iodine.....1 part.
Liquid pure vaseline.....100 parts.

Beneficial in scrofula, tuberculosis, asthma, and tertiary syphilis.

Dose, forty minims night and morning, daily.

4. Eucalyptol.....20 parts.
Iodoform.....1 part.
Liquid pure vaseline.....80 parts.

In infectious diseases, phthisis pulmonalis, and chronic bronchitis.

Dose, forty minims twice daily.

These solutions may be used in phthisis in rotation in periods of five days each. The reason of rotation is to avoid the cumulative effect of eucalyptol, which is manifested by depression and loss of appetite of the patient. These solutions influence, to some extent, the life of the bacilli.

With microbes in the drinking water, tyrotoxin in ice-cream, malaria in water-melons, Bright's disease in beer, and paralysis in iced tea, wherewithal may the thirsty soul refresh itself in summer time?

Treatment of Severe Burns by Continuous Baths.

W. J. LAWRIE, M. D., of Ayr, calls attention in the *Edinburgh Med. Journal*, July, 1887, to the treatment of burns by Hebra's water-bed. The bed is simply a form of bath, well suited to hospital practice, from its simplicity and efficiency, while the patient requires at the hands of nurses scarcely any attention. It is not cases of burning only that may be treated in this way—all diseases associated with loss of epidermis, viz., sloughing ulcers, erysipelas, pemphigus foliaceus, etc., which are associated with severe pain, supply excellent examples. The entire absence of pain and apprehension on the part of the patient, associated with the removal of old dressings and application of fresh ones, is a marked and favorable element in treatment by the bath. The wounded surfaces are continuously out of contact with the air, and as they are not covered with any form of dressing, the discharges escape at once into the water, and the wounds are kept clean. There is scarcely any limit to the time patients may remain in the bath; in more than one case they have been continuously submerged for 385 days and nights, only leaving the water for functional purposes.

In the Vienna General Hospital a separate ward is devoted to their use, and in the Royal Infirmary of Glasgow one has recently been established.

Hebra's water-bed consists of a zinc vessel, constructed in the framework of a bed. In the vessel an oblong iron frame is suspended by chains. The frame is so constructed that the portion where the patient's head is to lie may, by a hinge motion, be raised to an angle with the other part. The whole frame can be raised or lowered by means of toothed wheels. On the frame a thin mattress is laid; the patient rests on the mattress. When the zinc vessel has been filled with water, the bed, carrying the patient, is gradually sunk beneath the surface, taking care, of course, to keep the head out of water.

At first the patient feels the water too hot, upon which it must be cooled. Feelings of rigor now set in, and additional warm water must be added. After this he feels most comfortable—the pains have almost entirely disappeared.

The water-bed does not offer a remedy against the severe constitutional effects of all burns, nor against their fatal ending in all cases. Patients die of extensive burns under

this treatment as under any other, but they die at least free from pain.

On the other hand, the continual bath is an effectual therapeutic agent and a real benefit for patients and attendants during the long period of suppuration. By the ordinary methods such patients cannot be kept in a state of perfect cleanliness, because the dressing of extensive burns requires much time. Lifting and turning, as well as separation of the adhering bandages, are most painful. All of these disadvantages cease on the use of the water-bed. The patient lies and moves as he wishes, sleeps, eats, and enjoys himself according to his tastes. The wounds are always covered, always clean, and granulate normally, indeed often so luxuriantly that they must be repressed.

Hebra's water-bed is the best agent against pain, and the best therapeutic agent. Removal of scabs takes place earlier. Retention of pus is avoided. Danger of septicæmia and erysipelas is reduced to a minimum, fever ceases, sleep and appetite return.

A Consideration of the Results in 327 Cases of Tracheotomy, Performed at the Boston City Hospital from 1864 to 1887.

Drs. R. W. Lovett and John C. Munro, in the July number of *The American Journal of the Medical Sciences*, present an elaborate detailed study of the results of tracheotomy at the Boston City Hospital. They show that the results of operation in the series of cases studied are above the average in spite of the predominance of bad cases. They show that young children are especially liable to have extension of the diphtheritic process to the bronchi and lungs; in fact, that the chances are three to one that if they die they will die of suffocation. That, in Boston, tracheotomy at the hospital is most fatal at those times when diphtheria is most fatal in the whole city, and incidentally, that the mortality percentages from croup and diphtheria in the whole city vary by the month in unison. The cases with membrane in the pharynx at the time of operation are more likely to die than those where it is not present. That the mortality per cent. after tracheotomy rises steadily as the operation is done on the first, second, third, or fourth day of the difficult breathing. The nasal discharge, albuminuria and enlargement of the cervical glands, are symptoms of less moment than the character of the discharge from the trachea tube, which is the most important index of the progress of a case, and the recovery-rate varies nearly 50 per cent.

Treatment of Piles by Dilatation.

In the *Gaz. des Hôpitaux*, M. Verneuil publishes a note on the treatment of piles by dilatation. According to the author, ninety-eight cases out of a hundred may be radically cured by this simple process. The duration of the treatment scarcely ever exceeds eight days, during four of which the patient remains in bed, and during the remaining four days in his room. Piles of six, eight, ten, twelve, and fourteen years' existence have been completely cured in this manner. Even in cases in which the disease is complicated with true rectal prolapsus, dilatation should be had recourse to. During fifteen years that the author has practiced this method he has not met with one unsuccessful result. He prefers the speculum to the digital method of dilatation.

Ether as a Parasiticide.

The very simple and effective proceeding of killing pediculi pubis by one single application of ether has first been suggested by Dr. G. P. Thomas, of Alameda, in California. Ether recommends itself in preference to chloroform, which has been employed for the same purpose, as causing less pain and irritation to the skin of this very tender region.

Wonderful Delicacy of the Sense of Smell.

A curious series of experiments has just been completed by Drs. Emil Fischer and Penzoldt upon the sensitiveness of the sense of smell. These chemists used mercaptan and chlorphenol as their odoriferous substances, and experimented in a room of 230 cubic metres capacity. A gramme of the substance was dissolved in a liter of alcohol; 5 c. c. of the solution were again diluted to a known volume, and 1-3 c. c. of the latter solution measured out into a flask from which a fine jet could be directed by the experimenter to all parts of the room, the air of which was subsequently agitated by the waving of a flag. At a given signal a second experimenter stepped into the room, and took his olfactory observation, which was checked by the independent observation of a third person. The astonishing result was arrived at that our olfactory nerves are capable of detecting the 1-4,600,000 part of a milligramme of chlorphenol and the 1-460,000,000 part of a milligramme of mercaptan. The quantity of mercaptan present in the air of the room was 250 times less than the amount of sodium present in the air of

the room in which Bunsen and Kirchhoff made their experiments upon the sensitiveness of the spectroscope, when the sodium lines were just perceptible. — *Scientific American*, June 25, 1887.

NOTES ON CURRENT LITERATURE.

—Drs. Heitzman and Bödecker continue their valuable "Contributions to the history and development of the teeth," in the *Independent Practitioner*. The article for June contains several illustrations of the histology of the foetal tooth.

—Professor Shaler's article on the instability of the atmosphere, in *Scribner's Magazine* for August, will contain reproductions of a number of photographs taken immediately after disastrous tornadoes in the West, which show grades of destruction from centre to circumference of tornadoes, and the explosive effect of air contained in hollow walls.

—Macmillan & Co. announce a work entitled "Romantic Love and Personal Beauty: their development, casual relations, historic, and national peculiarities." The author, Mr. Henry T. Finck (Harvard, 1876), has collected a number of curious facts tending to show that romantic love (as distinguished from conjugal affection) is a modern sentiment, only about six hundred years old. They will publish immediately Sir John Lubbock's volume on "The Pleasures of Life."

BOOK REVIEWS.

Some Preventable Causes of Diseases Among Females. (Supplement Bulletin, North Carolina Board of Health.) By R. L. Payne, M.D., Lexington, N. C.

Our readers may object that the title of this eight-page pamphlet does not make it clear whether the females referred to are of the human species or of some form of lower animals. But on reading the pamphlet they will discover by the warnings against corsets, high-heeled shoes, over education, etc., that it is young women who are intended. The author gives many sensible suggestions—his own and cited from other writers—as to the methods calculated to improve the physical development of American women.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record.	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The edition for this week is 5,000 copies.

ADULTERATION OF FOOD.

Within the past few weeks the city of Philadelphia has been deeply stirred by the discovery of what is still doubtless going on, undiscovered, in many other large cities,—the use of poisonous mineral salts for the purpose of giving a rich color to bakers' and confectioners' wares. This is believed to have resulted in a number of deaths from lead poisoning, and the matter is being investigated by the authorities.

Sharp competition in trade and small profits have frequently induced manufactures to mix with articles of food cheaper ingredients, which, while not positively hurtful in themselves are less pure and less valuable than the genuine article. This, as a matter of course, is a fraud upon the community. But the selling of a deadly poison, with the knowledge that it is to be used as an adulterant for food, or the use of that poison in such adulteration, is something more than a *fraud*—it is a *crime*.

It will be noticed that we draw no distinction between those who knowingly and wilfully furnish the poisonous adulterants, and those who knowingly and wilfully use them. There may be a legal distinction,

although the District Attorney has not yet announced his decision upon this point; but to our mind, *morally*, if not legally, the crime is the same. There is little doubt but that the law will reach those who, knowing that "chrome yellow" or "chromate of lead" was poisonous, used the same to color their bread and cake; and it is to be fervently hoped that it will extend to those who confessedly furnished the same for that purpose.

Apart from the legal aspect of the case, the druggists and chemists who have been engaged in this nefarious business must be tried before another tribunal, by the standard of professional ethics.

As far as developed by the preliminary investigations, they are divided into two classes: those who admit a knowledge of the use to which the poison sold by them was to be put, and those who admit making sales, but deny all knowledge of the purpose for which the poison was procured. With the former class we have nothing to do. They are self-convicted of moral crime by their own admissions. As to the latter, we have some comments to make.

The profession to which they belong is an honorable one. It has at all times deservedly enjoyed the respect and confidence of the community. The individual qualities of intelligence, capacity and integrity are always conceded to it. When, therefore, any member of the profession so far forgets his high office, and prostitutes his superior intelligence, as to habitually sell, day after day, and week after week, to bakers and confectioners as regular customers a dangerous poison, usually used only in the manufacture of paint, without informing them of its dangerous character, without mark or symbol on the package to indicate its office, and without inquiry as to its future use, he must be held to the strictest measure of responsibility, and the presumptions must be wholly against him. To free himself from the imputation of guilty knowledge and guilty intent, these presumptions must be overcome by the most positive affirmative evidence; and failing in this, he must certainly lose the confidence of the community and the respect of his fellow members. We can conceive of no crime more serious, or more dangerous, than the adulteration of articles of daily food, and we trust that the services of the law will be speedily invoked to punish to the utmost those who are proven guilty, and to relieve from unjust suspicion those who are innocent of the most atrocious offense now charged against them.

THE TREATMENT OF HYDROPHOBIA.

The case of death from so-called hydrophobia, which is briefly reported on another page of the *REPORTER*, prompts us to make a statement in regard to the treatment of this disease, which we believe to be timely.

We have carefully studied this subject and have come to the conclusion that the use of morphia and atropia in the treatment of so-called hydrophobia is positively harmful. It does not appear that these medicines have ever saved the life of a patient, and it does appear that they have increased the excitement and frenzy in many cases, and that they have caused death by overwhelming the respiratory centres in some.

In the case which suggests these comments, the *New York Herald* states, on the authority of the attending physician, that after he and a colleague had concluded the case to be hydrophobia, the patient was "kept under the influence of anodynes administered with a hypodermic syringe," and that from hour to hour his vitality lessened, until he "died very quietly, his dissolution being hardly perceptible." This might suggest to the reader that this process was not unlike that observed in cases of poisoning with these drugs.

It was very hard to tell what was actually the cause of death in a case reported in a daily paper, and it is especially hard to feel confidence in reports about hydrophobia in the *New York Herald*. But it is safe to say that no good is to be expected from morphia and atropia, singly or combined, in the treatment of hydrophobia. They cannot do good and they may do harm.

There are two classes of hydrophobia. In one there is some organic disease, and the hydrophobic symptoms are caused by this disease. In this class of cases a correct line of treatment must rest upon a correct diagnosis of the organic disease present. The second class may be held to include cases of lyso-phobia, or the so-called hydrophobia of the imagination, or cases of grave hysteria, which may develop symptoms of hydrophobia, as well as those of other disorders. For this class of cases the treatment must be largely moral. Violence must be met by patience and forbearance, and not made more severe by counter violence. Fear must be met with confidence, anxiety with calmness. Even a rational diversion may be useful. A story is told of an English physician, who was bitten by a dog supposed to be rabid, and who some time after felt symptoms which he believed to be those of hydrophobia. At first he thought he must die; then he said to

himself: "I will not go to bed and give it up. I will go out, and see if I can shake this terror off." He then took up his gun, called his dog, and went out for a day's hunting. He hunted all day, returned home tired out, went to bed, slept all night, and got up well.

It might be a good idea to take any patient with supposed hydrophobia out of his house, away from his doctor and anxious friends, and see what would happen.

An important point in the treatment of so-called hydrophobia is to avoid giving water or food, or anything which the patient does not really desire.

Of medicine little is needed; but if anything is used we would suggest the treatment usual for acute mania, or even a hypodermic injection of $\frac{1}{4}$ grain of morphia followed in ten or fifteen minutes by chloroform inhalation. Overpowering or repeated doses of morphia are to be wholly avoided. But we believe that all cases in which there is no serious organic disease will yield to moral measures used with judgment and with assurance.

CLUB RATES.

The principle of club rates is a sound one. It is an expression of the fact that in order to increase his business, a publisher is willing to diminish his profits on individual items.

There are several ways of going about this. One way is to offer inducements to new subscribers. This we do not think fair to the thousands who so faithfully stand by the *REPORTER*.

Our way is to offer inducements to *old subscribers*, and is as follows:

Any paid-up subscriber to the *REPORTER* who sends us the name of a new subscriber, (or any number up to twenty), with five dollars for each name, will be credited on our books with *two dollars* for each name.

This credit shall be utilized in the purchase of any books or instruments at catalogue prices, or be applied to next year's subscription.

This is not unjust to the new subscriber, for, as soon as his name is entered, he can in turn obtain the same benefits by the same procedure.

It is not unjust to ourselves because a subscriber to the *REPORTER* is usually a subscriber for life, and with that fact in view we can afford to send the journal for one year at this price.

THE JOURNAL AND THE ASSOCIATION.

We notice that the *Journal of the American Medical Association* is being published as THE JOURNAL of the American Medical Association. We trust that this does not indicate the Editor's opinion of the relative importance of the Journal and the Association. If it does, we do not wonder that the paper on which the title page is printed has blushed a vivid pink.

NOTES AND COMMENTS.

THE MODERN TREATMENT OF COMMON DISEASES.

Pruritus of the Female Genitals.

The following formula is recommended by Meigs for pruritus vulvæ:

- R Boracis.....3 iv
Morphinæ hydrochlor.....gr. vi
Aque rosæ.....3 viiss
M. Sig.—Bathe the parts affected.

Between the applications, lycopodium or starch flower may be dusted upon the affected parts.

Vaneedem's prescription is:

- R Chloroform.....
Sulphuris.....
Sodii carbonatis.....āā. 3 iv
Morphinæ acetatis.....gr. vi
Vaseline.....3 v
M. Ft. ungt. Sig.—Rub upon the parts.

Lebert's formula is as follows:

- R Hydrargyri bichlor.....gr. viij—gr. xvi
Spt. camphoræ.....f3 viiss
Aque destill.....f3 x
M. S.—Bathe twice daily with the lotion.

For pruritus of the perineum, Hancke gives the following prescription, to be applied by the means of a sponge every two hours. For pruritus of the vulvæ, dilute four-fold:

- R Iodi.....gr. xv
Potass. iodidi.....gr. xl
Dissolve in aque dest.....f3 v
Add alcohol dil.....3 viiss

Pleuck's salve for pruritus pudendorum is made of the following:

- R Ungt. hydrargyri nitratis.....3 viiss
Hydrargyri oxidi rub.....gr. xx
Adipis.....3 iv
M.—ft. ungt.

Cazenave prescribes:

- R Zinci oxidi.....3 ss
Camphoræ.....gr. viii
Amyli.....3 viiss
M.—ft. pulvis. Sig.—Dust upon the parts.

Dr. Thomas, in cases of pruritus due to vaginal leucorrhœa, advises vaginal injections of the biborate of sodium in solution, and once or twice a week he cleanses the cervix thoroughly of mucus, and applies the nitrate of silver occasionally; chemically pure nitric acid is used with the hope of altering the secretion. Copious injections of water are continually used, and a suppository of cocoa-butter containing gr. v. of tannic or gallic acid, is placed against the cervix twice daily.

Trousseau recommends a solution carbonate of potassium (3 iii—f3 iv) for pruritus vulvæ. A formula advised by Fox is as follows:

- R Acetate of ammonia.....3 j
Dilute Prussic acid.....3 iss
Infusion of tobacco.....3 viij

M. Sig.—To be sponged on the part twice a day in pruritus ani or p. vulvæ.

Bartholow recommends the following lotion:

- R Hydrargyri chlor. corros.....1 part
Alum.....20 "
Starch.....100 "
Water.....2500 "

In case the pruritus comes from the presence of animal parasites, a mercurial treatment is advisable. The black or the yellow wash, or mercurial ointment may be used. The common sulphur ointment is powerful enough to kill the ordinary *Acarus scabei*.

Another formula of Thomas is very desirable as a vaginal injection and wash for the vulvæ:

- R Plumbi acetatis.....3 ij
Acidi carbolici.....3 ij
Tint. opii.....f3 j
M. Aque.....0 iv

Another topical application of demonstrated value is:

- R Bismuthi subnitrat.....
Acacia pulv.....āā. 3 ij

M. Sig.—Add water to the consistency of cream, and apply frequently with a brush.

The following is also excellent:

- R Pulv. acaciae.....3 ij
Bals. Peru.....f3 j
Ol. amygdalæ.....f3 iss
Aque rosæ.....f3 j

M.

And the following will be found an excellent lotion:

- R Acidi carbolici.....3 ij
Glycerinæ.....f3 j
Aq. rosæ.....q. s. ad f3 viij
M.—ft. Lotio.

It must not be forgotten that diabetic urine often produces obstinate and severe pruritus, so that examination of the urine is always advisable in such cases.

Hysterical or neurotic pruritus is best treated with a four per cent. solution of hydrochlorate of cocaine.

Ice Cream Poisoning--Electrical Theory.

Dr. George S. Hull, of Chambersburg, Pa., has, after a series of experiments, advanced the theory that ice cream poisoning is due to electrical action which takes place in the ice cream freezer, and which dissolves the zinc.

All of the zinc salts are poisonous, and as the symptoms of ice cream poisoning are those of mineral poisoning Dr. Hull thinks his theory worthy of consideration, and that it is entirely new. The modern ice cream freezer, with its zinc paddle and tin or copper can, would represent a tolerably good galvanic cell, provided the mixture in the freezer would attack the zinc.

Heretofore, the poisonous effects of ice cream have been attributed to impurities to the milk itself, to ptomaines, or to the action of micro-organisms. The most recently accepted theory is that of Prof. Vaughan, of Ann Arbor, the discoverer of tyrotoxin.

Dr. Hull experimented with ice cream materials which were tested and found to be perfectly pure. He reasoned that if any chemical action took place between the zinc paddle and the material in the freezer there would be generated a current of electricity. In conducting his experiments the doctor connected the zinc paddle and tin can by means of a copper wire with a moderately sensitive galvanometer introduced in the circuit. He first experimented with pure cream, which deflected the galvanometer seven degrees at freezing point. Dr. Hull concluded that, if pure cream caused a deflection, the other ingredients of ice cream would probably cause more, and in such case sufficient zinc would be dissolved to make the ice cream dangerous.

As a fact, he found that with half cream and half milk the galvanometer was deflected 25 degrees; with pure milk, 45 degrees; with one half cream, half milk, sugar and vanilla flavor, 58; the same mixture with corn starch, 44; the same mixture with eggs, 80. When these materials were allowed to stand so as to become partially sour, the deflection was greatly increased. Ice cream containing acid fruits or other acids caused still further deflections.

If Dr. Hull's theory is correct, it remains to be explained why most cases of ice cream poisoning occur at picnics. In explanation of this, he states that the cream for outings is generally made the day before, and that the paddle is left in the cream to be re-churned in case of softening. Of course,

the longer the zinc paddle remains in the freezer, the greater the amount of the poisonous zinc dissolved. In making of cream, salt often finds its way into the can, thereby very much hastening the solution of the zinc.

Dr. Hull is still engaged in these interesting experiments.

Surgery of the Spinal Cord.

On June 9th, Mr. Victor Horsely removed a tumor from the dorsal region of the spinal cord. The patient had been seen by Dr. Gowers, who diagnosticated a localised neoplasm, and suggested operative interference. The tumor measured about one inch and a quarter by half an inch; it was situated within the dura mater, and apparently grew from the ligamentum denticulatum of the spinal cord. It compressed the latter severely, causing violent spasms, pain and complete paraplegia. Although the operation was necessarily prolonged, the temperature has never reached 100°, and the wound is now practically healed. The patient has already recovered some power over the bladder, and the spasms and pain are rapidly diminishing. We believe this is the first case of the kind in which an operation has been attempted.

Pasteur's Recession.

M. Pasteur has renounced his intensive method, having found that it did not produce good effects, and has returned to the old system. It would be rather premature to say that, after all, the excitement made about the "radical cure" of hydrophobia was but the impression of the moment; but it cannot be denied that the medical world has considerably cooled down, and that a certain incredulity or distrust has taken the place of the enthusiasm so freely indulged in at the commencement. The papers, strange to say, seldom give any details now, and even cases of hydrophobia cease to be signalized. It would seem that even the canine species has made for the moment a truce with its nobler friends; in any case, such accidents cease to be reported with such effusion as last year. However, the Pasteur Institute has been subscribed to, and the ground bought for its erection. We will see by-and-by if the celebrated *savant* has really found the antidote to such a fearful malady. —Paris correspondent, *Medical Press and Circular*, June 8, 1887.

Death After a Dog's Bite.

On May 25th a little old dog, which had been years in the family, bit Mr. Gurnee, of Haverstraw, on the left thumb. The wound bled freely, and after some delay, Mr. Gurnee called on Dr. W. B. Bayley, who dressed the wound. Two days later, after resting uneasily, the dog died in a fit. Dr. Bayley dissected the body but could not account for the cause of death, and attributed it to a sort of epilepsy caused by old age. The fact that the dog was bitten some time before by a strange cur caused Mr. Gurnee some alarm. On Monday, June 20th, Mr. Gurnee complained of pain in the left hand and side. He slept well on Monday night. On Tuesday his pain was less intense, but his appetite was poor. On Tuesday night he was restless. Thus far only simple remedies had been given, and there was no indication of any serious result. On Wednesday morning he tried to drink, but could not swallow because of the spasmodic twitchings of the muscles of the throat; nor could he wash because of the effect of water on the muscles of his body. After several of these strong spasmodic attacks he recovered strength and was as well as usual. When Dr. Bailey and Dr. W. O. House arrived they agreed that it was a case of hydrophobia. He had some terrific spasms, during which his eyes would protrude and his muscles contract. After a terrible rigidity for about thirty seconds, when his limbs would be like iron bars, he would sink back entirely exhausted. These attacks would be brought on by the sight of water, a slight current of air or other trifling incidents. He was kept under the influence of anodynes administered with a hypodermic syringe. Dr. William A. Hammond, of New York, arrived at eight o'clock Wednesday night and entirely corroborated the diagnosis. The patient kept all night under the influence of drugs.

It was apparent from hour to hour that his vitality lessened. At ten o'clock Thursday morning he died very quietly, his dissolution being hardly perceptible. At no time did he exhibit any symptoms of barking or snapping as such patients sometimes do. The treatment was the administration of morphine and atropia hypodermically, which very materially assisted in quieting the spasms.

Curious Accident.

A drug clerk in Bridgeport, Connecticut, was charging a soda fountain recently, when it burst, and a large fragment struck him, causing a compound fracture of both legs below the knees.

The Thermal Death-point of Pathogenic Organisms.

An exact knowledge of the thermal death-point of pathogenic organisms is desirable, both as a matter of general scientific interest, and from a practical point of view. As biologists, we wish to know whether the vital properties of the living protoplasm contained in the minute vegetable organisms in question are destroyed at a uniform temperature, and if so at what temperature; or whether there is a considerable range in the limits of vital resistance to heat exhibited by different organisms of this class. As sanitarians, we wish to know what temperature can be relied upon for the destruction of disease germs in the excreta of patients suffering from typhoid fever, from cholera, and from other infectious diseases transmitted by means of the alvine discharges of the sick; whether boiling of infected clothing or of drinking water contaminated with diseased germs, is a safe means of disinfection, etc.

Various experimenters have recorded observations with reference to the thermal death-point of different microorganisms, but the paper by Dr. George M. Sternberg in the July number of *The American Journal of the Medical Sciences*, is the first effort to an extended inquiry, by means of a uniform method, with a view to determining the vital resistance to moist heat of the considerable number of pathogenic organisms now known to bacteriologists.

His results permit the following conclusions to be drawn:

The temperature required to destroy the vitality of pathogenic organisms varies for different organisms.

In the absence of spores, the limits of variations are about 18° F.

A temperature of 132.8° F. is fatal to the bacillus of anthrax, the bacillus of typhoid fever, the bacillus of glanders, the spirillum of Asiatic cholera, the erysipelas coccus, the virus of vaccinia, of rinderpest, of sheep-pox, and probably of several other infectious diseases.

A temperature of 143.6° F. is fatal to all of the pathogenic and non-pathogenic organisms tested, in the absence of spores (with the single exception of *sarcina lutea*, which, in one experiment, grew after exposure to this temperature).

A temperature of 212° F. maintained for five minutes destroys spores of all pathogenic organisms tested.

It is probable that some of the bacilli which are destroyed by a temperature of 140° F. form endogenous spores which are also destroyed at this temperature.

Cæsarean Section on a Cow.

Dr. C. Hamilton, of Ringgold, Ga., gives an account, in the *Southern Practitioner* for July, of a successful Cæsarean section upon a cow. The operation was rendered necessary on account of pelvic deformity caused by railroad accident, and was done April 20th last. The calf was saved and the mother recovered without an untoward symptom. No anesthetic was given. The doctor states that he began with the knife a little to the right of the median line, commencing just at the edge of the mammary glands, and cutting up, made an incision six or seven inches long, the cut in the uterus being as small as would possibly admit the escape of the calf. As the membranes had not ruptured, he waited a few minutes for the sac of waters to form (which they did very readily), so as to dilate the cut in the womb. He then ruptured the membranes and delivered the calf, and in a few minutes it was up walking around. He used a catgut suture in closing the cut in the uterus and abdominal walls, and in a few minutes after the cuts were closed the cow got up and let the calf suck. There was very little swelling or supuration. The lochial discharge commenced at once from the vagina and continued the usual time.—*Miss. Valley Med. Monthly*, July 10, 1887.

Pyridin in Dyspnoea.

Kovacz has been experimenting in Nothnagel's clinic on the use of pyridin in dyspnoea. Patients inhaled 5 to 20 drops in about an ounce and a half of water. He finds that it diminishes dyspnoea, though its effects are not constant. It acts best in nervous asthma, and is least efficacious in the asthma of cardiac disease. With care there is no danger in its employment. In one case vertigo, vomiting and diarrhoea followed its use.—*Cent. f. klin. Med.*, No. 46, 1886.—*Medical Chronicle*, July, 1887.

—The Virginia State Medical Society is to meet at Richmond on October 19th, 1887.

—Three young internes of the Newark City Hospital have received a very severe lesson. A patient was brought to the hospital comatose. He was thought to be suffering from alcoholism, and he was treated accordingly, being given a douche and strong cutaneous irritation. The patient died, and on autopsy there was found a tumor of the brain. A coroner's jury investigated the case, and the internes were thereupon arrested for manslaughter.

CORRESPONDENCE.

Laceration of Tendo Achillis.

EDS. MED. AND SURG. REPORTER,

SIRS:—I have a case of laceration of the tendo Achillis, with fracture of a portion of the posterior part of the os calcaneum, which I wish to report to you and ask your advice about treatment.

Mr. P., age 40, on the 24th day June fell from a step, a distance of about eight feet; he struck on the ball of the foot; he says there was a sensation as if something had given way, with a loud snap; he could not keep his weight on the limb; there was much swelling and pain, with a gap of about one and one-half inches. Now, is Monro's apparatus as good a one as I can use? If you will please kindly give me advice, through the columns of the REPORTER, I will be greatly obliged to you. Yours truly,
Elyria, Ohio. J. V. S.

[Monro's apparatus is not so good in the treatment of a case like this as a permanent dressing made of plaster of Paris, or starch, or parafine. Or a tin trough splint can be made to hold the foot at a right angle to the leg. To make this form of splint, take a piece of moderately heavy tin, as long as the foot and two-thirds of the leg, and as wide as the whole circumference of the middle of the leg. At a point as far from one end as the point of the heel is from the toe, cut toward the middle line of the tin with a heavy pair of shears, through one-third of its width on each side; bend the sides up to make a trough, and bend the foot end up at right angles to the leg end. Now punch a hole where the corners overlap at the angle, and fasten them with one of the cheap paper fasteners, which every stationer sells. This will make an admirable splint for any case to which a rectangular trough is applicable.—Editors of the REPORTER.]

Treatment of Stomatitis.

EDS. MED. AND SURG. REPORTER,

SIRS:—1. Will you, or some reader of the REPORTER, furnish formulas, through the REPORTER, for canker, or sore mouth in infants?

2. Will you state if sore mouth is ever caused by the effect of mercury in chalk mixture?
J. E. STILES.

Red Lake Falls, Minn., June 27, 1887.

[In reply to question 1, we would suggest the following line of treatment:

For local and general antiseptic effect :

R. Potas. chlorat. 3 j
Aqæ destillat. f 3 ij
Syr. simplicis. f 3 j

M. Sig.—Use as a wash for mouth and give a teaspoonful every four hours.

Or,

R. Acid. boric. 3 ij
Infus. med. sassaf. f 3 ij
Glycerinæ. f 3 j

M. Sig.—Use as a wash for mouth and give a teaspoonful every four hours.

To regulate the bowels :

R. Ol. ricini,
Syr. rhei aromat. āā f 3 j

M. Sig.—Give one or two teaspoonfuls, according to age.

As a tonic :

R. Ferri et potas. tart. gr. xxiv
Aqæ bullient. f 3 j
Syr. Zingiber. f 3 ss

M. Sig.—Give a teaspoonful t. d.

In reply to question 2, we would say that chalk mixture contains no mercury ; if mercury were *added to it*, it would be very likely to produce a constitutional effect, perhaps a stomatitis.—EDITORS OF THE REPORTER.]

Iron and Salicylic Acid.

EDS. MED. AND SURG. REPORTER,

Sirs: Permit me to lay before the readers of the REPORTER the following combinations of iron with salicylic acid, which I have found useful:

No. 1. For Rheumatism.

R. Water. 3 oz.
Bi carb. soda, ... 80 grs.
Acid salicylic, ... 160 "
Liq. ammon. citrate, ... 1 1/2 oz.
Muriated tinct. iron, ... 160 m.
Glycerine, ... 2 oz.
Elix. orange, ... 6 drs.
Water, ... q. s. ad 8 oz.

Mix and shake well. Dose.—A teaspoonful every three or four hours.

With this mixture can be added either tincture of colchicum, digitalis, or aconite, in proper doses, with great advantage.

No. 2. A Special Tonic.

R. Liq. ammon. citrat., ... 1 1/2 oz.
Soda salicylate, ... 80 grs.
Citrate of iron, ... 80 "
Glycerine, ... 2 oz.
Elix. orange, ... 6 drs.
Water, ... q. s. ad 8 oz.

Mix and shake well. Dose.—A tablespoonful every three or four hours.

No. 3. A Good Tonic.

R. Basham's mixture, U. S. Disp., ... 4 oz.
Sodii salicylatis, ... 1 dr.
Citric acid, ... 10 grs.

Mix and shake well. Dose.—A teaspoonful every three or four hours.

(After the salicylate of soda is mixed well with Basham's mixture, add the citric acid.)

No. 4. A General Tonic.

R. Aqæ, ... 5 oz.
Sodii bi-carb., ... 60 grs.
Ammon. carb., ... 40 "
Acid salicylic, ... 160 "
Glycerine, ... 1 oz.
Elix. orange, ... 6 drs.
Cit. of iron and quinine, ... 40 grs.
Citric acid, ... 10 grs.

Dose.—From a dessert to a tablespoonful every three or four hours.

Mix the soda, ammonia, water, and salicylic acid together in a graduated eight ounce glass measure, stirring well with a spatula until well dissolved. Mix the citrate of iron and quinine in a half ounce of water, and when dissolved add it slowly, constantly stirring, until all is mixed ; then add water to make eight ounces, and finally drop in the citric acid.

Basham's mixture, as ordered by the U. S. Dispensatory, should be made with glycerine instead of simple syrup. It soon spoils when made with syrup, but when glycerine is substituted, it keeps pure a much longer time.

Mixture No. 4, of all other mixtures of salicylic acid and iron, is free from the properties which produce headache and sick stomach ; and is an admirable general tonic, and can be taken a long time without producing any of the physiological effects of salicylic acid.

I have used this formula in painful menstruation, and in cases of neuralgic pains about the ovaries and uterus of nervous, delicate, and hysterical females, with great satisfaction. In combination with eight or ten grain doses of iodide of potassium, it has proved in my hands, an admirable alterative and tonic in secondary syphilis, attended by a debilitated condition of the general system. It combines well with chlorate of potash, hypophosphate of sodium and hypophosphate of calcium. A drachm of fluid extract of cimicifuga, and from three to five drops of Fowler's solution added to each dose, I have found to act well in cases of chorea.

These formulæ were originated by me after great trouble. They all form reddish-brown or wine-colored solutions, and they will mix with Fowler's solution, iodide of potassium, either of the bromides, and with any of the vegetable bitter tonics, either the tinctures or the fluid extracts. The doses can be made or less, and given at longer or shorter intervals, to meet the indications for which the may be prescribed. These mix-should be carefully made in an eight ounce graduated glass measure, and the one most conveniently made is that of the union of salicylate of soda and citric acid with Basham's mixture.

J. B. JOHNSON, M. D.

922 New York Ave., Washington, D. C.

NEWS AND MISCELLANY.

Fiske Fund Prize.

The Trustees of the Fiske Fund propose the following subjects for the year 1888:

I. What changes has the acceptance of the germ theory made in measures for the prevention and treatment of consumption?

II. Antisepsis in medicine and surgery; with original observations and experiments.

For the best dissertation on either subject, worthy of a premium, they offer the sum of two hundred dollars.

Every competitor for a premium is expected to conform to the following regulations, viz. :

To forward to the Secretary of the Trustees, George L. Collins, M.D., Providence, R. I., on or before tenth day of May, 1888, free of all expense, a copy of his dissertation, with a motto written thereon, and also accompanying it a sealed packet having the same motto inscribed upon the outside, and his name and place of residence within.

Cooper Hospital, Camden, N. J.

At a meeting of the staff of the Cooper Hospital, on July 13th, Dr. H. Genét Taylor was appointed secretary and chairman.

The physicians and surgeons who will be on duty at the hospital were divided as follows: July, August and September, Dr. Dowling Benjamin, surgeon; Dr. Mecray, physician. October, November, December, Dr. O. B. Gross, surgeon; Dr. D. P. Pancoast, physician. January, February, March, Dr. J. F. Walsh, surgeon; Dr. W. A. Davis, physician. April, May, June, Dr. E. L. B. Godfrey, surgeon; Dr. H. Genét Taylor, physician.

The graduates who are appointed resident physicians will receive \$100 a year and board.

Fatal Mistake of a Nurse.

At Dayton, Ohio, July 11th, an inmate of the Southern Ohio Insane Asylum, died from an overdose of morphine, administered by mistake by a nurse. The patient was an incurable and in a weak condition. Two bottles, one containing chloral and the other an eye wash, both properly labeled, were sent to the patient's room, and the morphine was given by mistake for a dose of the chloral. The nurse who made the mistake has been in the asylum a number of years, and has always been regarded as faithful and conscientious. She is almost prostrated by the sad accident.

Water Supply of Mount Holly.

The trouble over the water supply at Mount Holly, N. J., has culminated in the formation of a syndicate for the erection of new water works to secure purer water than that now furnished. Already \$10,000 has been offered for the formation of the new company, and one firm has agreed to take half the stock.

A Poor Imitation of Hydrophobia.

A man giving the name of William Doan, and his residence in Philadelphia, was arrested in Camden, N. J., recently. He would bark like a dog, get down on his hands and feet, and finally took his hat and tore it to pieces with his teeth. After he had recovered from the convulsions he stated that he had been bitten by a dog about two years ago. He was allowed his liberty, and directed to Philadelphia.

Death from Pollution of a Well.

A report from Wilmington, Del., dated July 12, states that a man and his wife and their eleven-months old child died of dysentery, attributed to the pollution of their drinking water with decomposing meat.

It was brought out at the inquest that a piece of fresh meat had been placed in an old kettle and suspended by a windlass in the well for preservation. For some cause or other, the meat was forgotten and had putrified and been blown by flies. The tin receptacle in which it was hanging contained numerous holes, and the decaying meat fell into the drinking water. All who used the water were affected. The two surviving children were removed from the house in time to at least prolong their lives.

Parotitis and Pelvic Disease.

Mr. Stephen Paget has collected no less than 101 cases of parotitis consequent upon injury or disease of the abdomen or pelvis. Of this number, 10 were due to injury or disease of the urinary tract; 18 were due to injury or disease of the alimentary canal; and 23 were due to injury or disease of the abdominal, the peritoneal, or the pelvic cellular tissue. The remaining 50 were due to injury or disease, or temporary derangement of the generative organs. Under the latter term are included slight blows on the testis, the introduction of a pessary, menstruation, and pregnancy. This form of parotitis appears to be non-pyæmic, to have no definite incubation stage, and to end very often in suppuration. Mr. Paget considers that the sequence of disease is due to influences acting through the nervous system.

Colorless Tincture of Iodine.

Dr. A. J. Brewer, of Mountain Home, Arkansas, writes to the *Atlanta Med. and Surg. Journal*: "I find a formula in the fifteenth edition of U. S. Disp. for making colorless tincture of iodine. Equal parts of compound tincture of iodine and aqua ammoniæ mixed constitutes the formula. This must stand for twenty-four hours before it becomes colorless. I find by adding four drops of carbolic acid to the ounce, and shaking, it becomes colorless instantly."

Gangrene of Upper Extremities Due to Arteritis.

In gangrene due to arteritis obliterans the lower extremities are usually affected. But WILL has recently reported (*Centralblatt für Chirurgie*, 1887, No. 7), a case observed in Schönborn's Clinic in which the gangrene occurred in the arm. A shepherd, 52 years old, had a blood blister on the third finger of the left hand four weeks before his admission to the hospital, and excessive pains in the whole limb; which did not cease even after removal of the diseased finger. Before the operation, it was noticed that the radial and ulnar pulse was absent on both sides, the arteries felt like rigid tubes. No irregularity of the heart could be ascertained. The gangrene of the left hand advanced slowly, and a similar process developed in the right hand, and rapidly extended towards the forearm. The patient died of sepsis four weeks after admission. The post-mortem showed chronic arteritis with formation of small calcareous masses in the middle coat. The arteries of the forearm were totally obliterated and filled with softening thrombi. The walls of the veins were healthy, but contained puriform degenerated thrombi. The aorta and its descending branches were healthy as far as the origin of the external and internal iliacs. The cause of the disease was unknown.

The Health of Philadelphia.

No epidemic or zymotic disease, with the single exception of measles, has prevailed in Philadelphia for the past six months. There was not a single death from small-pox. The number of deaths from typhoid fever was reduced from 268 in the first half of 1886 to 232 in the same period of 1887. Croup, diphtheria, scarlet fever each had fewer victims this year than in previous years.

High Death Rate in New York.

President Baylis, of the Board of Health, said recently:

"I am informed by Dr. James B. Taylor, of this Department, that since the 1st of January there have been deaths in New York from certain contagious diseases as follows: Diphtheria, 1132; measles, 663; scarlet fever, 246. If this rate of mortality from these causes should continue throughout the year they would cause a total mortality of between 3,900 and 4,000. In a report prepared by Dr. Taylor it was shown that the prevalence of these diseases is due to the ignorance of the people as to their dangerous character, and their carelessness in the matter of the necessary precautions."

State Pharmaceutical Board.

The State Pharmaceutical Examining Board met at Harrisburg, July 12th, and elected the following officers: President, Alonzo Robbins, Philadelphia; secretary, Harry B. Cochran, Lancaster; treasurer, Frederick H. Eggers, Allegheny. The Board consumed its entire session until this evening, preparing forms for applicants for registration. The examination will not begin until next fall.

OBITUARIES.**DR. DAVID DAVIDSON.**

Dr. David Davidson died in Philadelphia, July 14, 1887, of chronic Bright's disease. He was born in this city about forty years ago, and, after receiving a public school education, studied in the medical department of the University of Pennsylvania, from which he was graduated in 1871.

After securing his degree, he served in the Pennsylvania and Orthopædic Hospitals. At the time of his death he was one of the consulting physicians of the Jewish Hospital, and was a member of the County Medical Society.

JARED LINSLEY, M. D.

Jared Linsley, M. D., a graduate of the College of Physicians and Surgeons of New York, of the class of 1829, died on July 12th, in Northford, Conn., in his eighty-fourth year.

GEORGE ENGS, M. D.

George Engs, M. D., of Newport, R. I., died on July 7th, at the age of forty-five. He was a graduate of the College of Physicians and Surgeons of New York, and served on the house staff of Charity Hospital soon after obtaining his degree. For several years he had been one of the leading physicians of Newport.

JOHN S. BAGG, M. D.

John S. Bagg, M. D., of Springfield, Mass., died on July 9th, at Nantucket, where he had gone on account of ill-health. Dr. Bagg was thirty-eight years old, and a graduate of the Medical Department of the University of Pennsylvania, of the class of 1873. He served eight years in the medical corps of the navy, in which at the time of his resignation he was a passed assistant surgeon.

SAMUEL H. HENRY, M. D.

Samuel H. Henry, M. D., of Baltimore, died July 12th, in the sixty-ninth year of his age. He was a native of Somerset county, Maryland, and was graduated from the University of Pennsylvania, Department of Medicine, in 1839. He practiced his profession at Elkridge Landing, Md., until 1876, when he settled in Baltimore. His death is said to have been due to paralysis.

There are no changes in the Medical Corps of the Navy for the week ending July 16, 1887.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from July 10, 1887, to July 16, 1887:

Lt.-Col. A. H. Heyer, Surgeon, ordered to Ft. Columbus, N. Y. H.

Major J. H. Janeway, Surgeon, ordered to Benicia Bks. as Post Surgeon; also, as Attending Surgeon at Benicia Arsenal, Cal.

Capt. H. P. Birmingham, Asst. Surgeon, ordered to Ft. Myer, Va.

1st Lt. C. E. Woodruff, Asst. Surgeon, ordered to Ft. Mackinac, Mich.

Capt. C. K. Winne, Asst. Surgeon, ordered to Ft. Wadsworth, N. Y. H.

Capt. Valery Havard, Asst. Surgeon, ordered to Ft. A. Lincoln, D. T.

Capt. L. M. Mans, Asst. Surgeon, ordered to Ft. Schuyler, N. Y. H.

Capt. J. B. Girard, Asst. Surgeon, ordered to Ft. Lowell, Ariz.

1st Lt. J. D. Poindexter, Asst. Surgeon, ordered to Camp Poplar River, M. T.

1st Lt. C. N. B. McCauley, Asst. Surgeon, ordered to Ft. Gibson, Ind. T.

Capt. C. B. Byrne, Asst. Surgeon, ordered to Ft. Washington Bks., D. C.

Capt. T. E. Wilcox, Asst. Surgeon, ordered to Ft. Niobrara, Neb.

Major H. Lippincott, Surgeon, ordered to Ft. Union, N. M.

Major P. J. A. Cleary, Surgeon, ordered to Ft. D. A. Russell, Wyo.

Major D. G. Caldwell, Surgeon, ordered to Assiniboine, M. T.

Capt. G. H. Torney, Asst. Surgeon, ordered to Ft. Robinson, Neb.

Capt. Walter Reed, Asst. Surgeon, ordered to Mt. Vernon Bks., Ala.

Capt. J. H. Patzki, Asst. Surgeon, ordered to Ft. Huachuca, A. T.

Capt. R. G. Ebert, Asst. Surgeon, ordered to Ft. Custer, M. T.

1st Lt. J. E. Pilcher, Asst. Surgeon, ordered to Ft. Monroe, Va.

Capt. J. de B. W. Gardiner, Asst. Surgeon, ordered to Ft. Washakie, Wyo. T.

1st Lt. A. R. Chapin, Asst. Surgeon, ordered to Newport Bks., Ky.

Major W. H. Forwood, Surgeon, ordered to Ft. Snelling, Minn.

Capt. H. O. Perley, Asst. Surgeon, ordered to Wayne, Mich.

S. O. 156, A. G. O., July 8, 1887.

S. O. 159, par. 2, A. G. O., July 12, 1887—assigns Capt. W. Matthews, Asst. Surgeon, as member of Army Retiring Board at Washington, D. C., and relieves Capt. J. O. Skinner, Asst. Surgeon.

Captains S. M. Mans and H. O. Perley, Asst. Surgeons, ordered to accompany the 11th Inf. in changing station from Dept. Dak. to Dept. East. S. O. 158, A. G. O., July 11, 1887.

Capt. R. G. Ebert, Asst. Surgeon, will, in changing station from Ft. Hamilton, N. Y. H., to Ft. Custer, Mont., accompany the 12th Inf. from Dept. East to Dp. of Dak. S. O. 156, A. G. O., July 12, 1887.

Capt. E. F. Gardner, Asst. Surgeon, ordered to accompany the 11th Inf. from Madison Bks. to Duluth, and to return with 11th Inf. S. O. 143, Div. Atlantic, July 13, 1887.

1st Lt. F. V. Walker, Asst. Surgeon, granted leave of absence for 4 months. S. O. 160, A. G. O., July 13, 1887.

1st Lt. Julian M. Cabell, Asst. Surgeon, ordered for duty as medl. officer at Dept. Rifle Camp, near Bellevue, Neb., Aug. 1, next. S. O. 66, Dp. Platte, July 5, 1887.

A board of med. officers, to consist of Major J. S. Billings, Surgeon; Capt. W. Matthews, Asst. Surgeon; Capt. F. C. Ainsworth, Asst. Surgeon, is constituted to meet in this city for the examination of a candidate for admission to the Medical Corps of the Army. S. O. 157, A. G. O., July 9, 1887.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the two weeks ending July 16, 1887:

W. H. Long, Surgeon, granted leave of absence for thirty days on account of sickness. July 16, 1887.

H. W. Austin, Surgeon, granted leave of absence for thirty days. July 16, 1887.

R. B. Watkins, Asst. Surgeon, relieved from duty at Marine Hospital, Detroit, Mich.; ordered to assume charge of service at Evansville, Ind. July 9, 1887.

PNEUMONIA; COMPLEX IN ITS ORIGIN AND NATURE.

BY ENOS T. BLACKWELL, M. D., OF CEDAR-
VILLE, N. J.

When our knowledge of diseases becomes so perfect that we can, with unerring precision say of each group of symptoms, however imperfectly some of its factors may be developed, that it constitutes this or that affection; and when all apparent discrepancies are disposed of through the extension of knowledge, there will be less occasion for dogmatism in respect to disorders presenting themselves with signs, whose resemblances are delusive and variable in their character according to the nature of their cause.

Medical writers and thinkers are far from being unanimous as to what constitutes pneumonia; and, until they are, we shall hardly escape criticism if we declare that this or that plan alone is appropriate in the treatment of the condition or aggregation of symptoms which is so denominated.

I am satisfied that there are true pneumonias, definite in their manifestations and amenable to certain lines of treatment. Such are the croupous and catarrhal pneumonias of Juergensen.¹ I am also persuaded that there are certain affections entirely different in their nature, which are not curable by any treatment applicable to inflammation, yet which are characterized by many of the leading features of pneumonia proper. It is,

therefore, not difficult to believe that Doctors Corson and Maxwell may both be right in their judgment of pneumonia, as seen by them; and, that their treatment is suitable in their respective cases. I shall, however, quote from cases of my own to show that all forms of chest trouble characterized by pain, rapid breathing, fever, bloody expectoration, etc., are not alike in their character or cause; and that the treatment successful in one form is useless, nay, injurious in the other.

That there may be a form of pneumonia strictly malarial (so-called); and, that it is quickly amenable to the action of the cinchona salts, I cannot doubt. Notwithstanding, however, that I have practiced much in malarial districts, and have habitually given quinine in all stages of pneumonia, I am compelled to avow that I have never recognized a single case that proved to be distinctly malarial; or, one in which quinine alone sufficed for a cure. Instances may be related of other forms of disease which the malarial element completely dominated; and which, by analogy, give color to the claim that pneumonia may be produced or controlled by this influence. An inflammatory affection of such origin and control is here quoted from a paper heretofore published by me,² July 5th, 1880. T. H. has tenderness of the scalp and inflammation of the left eye, which is particularly painful during the night. He has also tenderness of the liver, and a pain in the top of the right shoulder. There is also fever, of which he had a paroxysm on July 3rd. A former attendant, who dis-

² On quinine in fevers and disorders accompanying them. MED. AND SURG. REPORTER, vol. xliii, p. 355.

¹ Ziemssen's Cyclopædia.

cerned only the intense suffering in the eye, directed his attention alone to that organ; treating it by instillation of nitrate of silver, but ineffectually. I gave him half-drachm doses of iodide of potassium, in one pint of water, in the morning, fasting, as directed by Dr. Guit  ras, in the *Philadelphia Medical Times*, vol. x, page 446. This for the liver. Through the remainder of the day, he had liberal doses of quinidi   sulphas, with opium. July 7th, had pain in the head during the past night, but the inflammation and pain in the eye are less; the tongue is coated, but moist; the urine is free, and the appetite improved. The treatment to be continued as before: a weak ointment of calomel and lead cerate being applied to the eye. On July 10th he was so far recovered as to be discharged, taking only a chinchona tonic.

I have been accustomed to use quinia in the outset of all cases of pneumonia, for its modifying effect on the fever which pertained to it, or was its source; yet, one of my latest cases, which was accompanied by pleurisy, is a conspicuous instance of its failure to check the process going on in the lungs.¹

Mrs. L., a young married woman, was taken with a cold and hoarseness, February 16, 1887. At my visit on that day she had a very high fever and general pains throughout the body; the pulse-rate was 140. The treatment was two grains quinine sulphate every two hours, and two grains opium every four hours. She received the same treatment until February 19, when on account of severe vomiting, she took potassium citrate, creosote-water, and hyocyamus, but no opium. Her skin was constantly bathed in perspiration, yet there was no remission of the rapidity of the heart's beating. She had been using externally from the commencement a remedy of her own—a tar-plaster.

February 20, 10 A. M.—The patient has had a very severe pain during the night, as also a constant cough. The pain occupies the entire area of the left chest from scapula to sternum, and from the axilla to the free border of the ribs. She lies upon the right side, with the left arm close to the affected region, and is unwilling to move either the body or the arm. Early in the morning she commenced to expectorate bloody mucus: the respirations reach 38 per minute, and the pulsations 124; ratio, 1 to 3.3. The skin is moist, the tongue coated, and the stomach

quiet. A plaster of cantharides was so placed as to conform to the painful area, and the following medicines were prescribed, viz., three grains of quinine every two hours, and three grains of opium every six hours.

February 21.—The plaster has caused a perfect blister. The patient is free from pain; the skin is moist; the cough and expectoration moderate; the sputa less bloody. The respiration is 22, and pulsations 102; ratio, 1 to 4.6. She sleeps considerably.

February 25.—Respiration 19, pulse 76.

February 26.—Took leave, the patient having recovered in eleven days.

Here is a patient who, in three days, had received perhaps a drachm of quinine, the influence of which was doubtless continued, with a good deal of force, until the full development of the pneumonia, on the fourth night (February 19). At this time the respirations were 38, and the pulsations 124—a ratio of 1 to 3.3. Twenty-four hours later, when the effect of a full blister had been obtained, the respirations had fallen to 22, and the pulsations to 102, the ratio was much increased—1 to 4.6. Without wishing to belittle the effect of the quinine and opium, which were used during the operation of the blister, no one can, I think, doubt that the last factor arrested *the morbid process*, and put an end to the disease, without any *secondary lesions*.

There is a form of pneumonia very different from the foregoing—different in its origin and nature; different in the course of treatment required; and different in its results. I present the following from a paper on *Adynamic Pneumonia*, published by me in the *Philadelphia Medical Times*, vol. x, p. 549, *et seq*:

“The pneumonia . . . exhibits from its beginning not vigor but great weakness and tendency to prostration. The patient lies upon his back. The pulse is rapid, while the surface may be bathed in perspiration. The sputa, the mucous membranes and the skin are dark-colored. There is great restlessness and speedy loss of strength. This is typhoid pneumonia, or pneumonia with hypostasis, and the treatment useful in the sthenic variety is worthless, if not absolutely pernicious. The pulse rises instead of falling; the difficulty is exaggerated instead of lessened, and the powers of life quickly fail. The cases subjoined are from the paper named.

“Mrs. S., aged about 50 years, of a delicate constitution, was taken January 31, 1875, with chillness and pain in the side, a high fever following. I saw her at 9 o'clock A. M.,

¹ On blistering the surface of the body in internal inflammations.—*Philadelphia Medical Times*, vol. xvii, p. 624.

February 1. She had slept none during the night, and was lying upon the back, profusely perspiring. Her breathing was very quick and shallow, and she was expectorating a bloody mucus. The bowels were shut; pulse, 112. A blister was immediately applied to the whole of the affected part, and the following medicines ordered:

R Hydraz. chl. mit. grs. xij;
Sodii bicarb.
Quinæ s. āā. grs. xij.

Mix, and divide into eight powders, one to be taken every three hours.

R Potassii citratis. 3 j;
Ex. aconiti fl.
Ex. digitalis fl. āā. gtt. xij;
Sp. ætheris nit.
Aquæ, āā. 3 j.

Mix.—A teaspoonful to be given alternately with the powders.

Morphine was prescribed for the restlessness and to procure sleep.

February 2.—I was sent for in haste, arriving at 10 A. M. The breathing had not improved; the tongue was dry; the bowels still closed; the urine hot and red; the skin moist; the voice whispering; the pulse quick and weak; the respiration bronchial; and every movement was attended with exquisite pain. As the epispastic had failed to produce a sufficient blister, the surface was painted with cantharidal collodion. Seven o'clock P. M. the patient had dozed some, and seemed to breathe easier; the urine was freer, and there had been an evacuation by the bowels. Medicine continued as before. On the morning of February 3, the fourth day of the disease, collapse occurred, and she died.

W. R. R., a farmer, about forty years of age, was taken, March 28th, 1875, with chills, alternating with fever and free epistaxis. When I saw him the day following, he had "a catch" in the left hypochondrium, cough, and expectoration of mucus, with some blood. The pulse rate was 100; the skin moist, but red and congested; the soft palate, also, presenting a punctate redness. The bowels were moving freely. No false sounds could be detected over the affected part. The same medicines were ordered as in the preceding case, except the calomel, and domestic applications were made to the chest. The next day he was coughing up rusty mucus; was sweating profusely; his headache continuing; pulse unchanged. The chest was still resonant, and he was careful to show me that he could fully inflate his lungs. Belladonna was added to the medicine to check the sweating. In the night he became delirious and very restless,

complaining of his bowels and head. I was summoned, arriving at 1 A. M. of April 1st. His pulse was unchanged and he was drenched with perspiration. The iodide of potassium was substituted for the citrate, and paregoric elixir was added. At 5 P. M. there was less perspiration, the pulse was 105, and epistaxis had recurred. April 2d, the tongue was cleaning; pulse, 102. April 3d, had had fever during the night, succeeded by free sweating; was very restless, needing morphine; his urine was loaded with straw-colored precipitates; the tongue was moist, but heavily coated, except at the tip; the bowels were tender and tympanitic; the pulse 111 and rather weak. He still raised stained mucus, and auscultation revealed some blowing respiration in the posterior part of the chest, but no râles. Iodine, dissolved in cantharidal collodion, was now applied to the chest, which was enveloped in oiled silk. Yolk of egg, wine, and milk were ordered. At 7 P. M. of same day the patient was delirious, with a pulse at 125. He was in a gentle perspiration. . . . The patient continued to fail, dying on the ninth day of the disease.

August 2d, 1871, took charge of the following case: E. P., farmer, aged 34, took a cold about the preceding holidays . . . and cough, attended by foul corruption, lasting to the beginning of May. . . . His immediate sickness dates from July 24th, commencing with an agony in the loins and hips and a pain in the head, accompanied apparently by congestion, as he says he knew but little. These symptoms in less severity, with a morning and evening paroxysm of fever, prevailed until the date of my visit, which was during an interval; the pulse marking 78. The tongue had a thick, creamy coating, and he had a cough, with mucoid sputa. His urine was nearly thick; his bowels had been costive throughout, but he had taken "salts" twice, with a hypercathartic effect. On physical exploration of the chest, there was found dullness on percussion in the right lung, anteriorly and posteriorly, with prolonged expiration and increased vocal vibration at apex; on the left side there was dullness in front only. He was ordered a pill composed as follows:

R. Quinæ sulph.
Cinchonæ sulph. āā ʒ j
Acid. sulph. arom., q. s.

Mix and divide into ten pills, one to be taken every four hours alternately with a mixture having expectorant, diuretic, and anodyne properties.

The day following, the pulse was as before, the tongue appearing cleaner. August 4, a sub-

crepitant *râle* was heard in the lower part of the right lung, with large bubbling. The cough was tight and the expectoration streaked with blood. The tongue was cleaner. The quinine was continued as before and the iodide of potash added to the mixture, with gentian as a tonic. On August 5th the pulse was 96. A blister was applied to the chest as a counter-irritant. From this time till the 10th the pulse gradually rose, notwithstanding the constant saturation of the system with quinine; the cough was tighter and the breathing shallower. On the 11th the tongue was chapped and the whole pharynx covered with aphthous-looking exudation on a purplish ground. There had been high fever the preceding night, with headache. Death occurred on the 15th, the fourteenth day of treatment and the twenty-fifth of the disease.

A review of the symptoms of the foregoing cases show many which coincide with those of the infectious fevers, *e. g.*, the agony in the head and loins, the lividity of surface, the looseness of the bowels, and the epistaxis; and I have been led to think well of the idea of Juergensen¹ formulated in this question to himself: "Are the pulmonary lesions and the fever due to a common cause?" His reply on a succeeding page is clear and unequivocal: "*Croupous pneumonia is a constitutional disease, and is not dependent on a local cause. The pulmonary inflammation is merely the chief symptom, and the morbid phenomena are not due to the local affection. Croupous pneumonia belongs to the group of infectious diseases.*"

It may not be amiss to quote a paragraph or two, additional, from the paper by the same author. "Croupous pneumonia can no more be produced by the excitants of inflammation than can the characteristic lesions of typhoid fever." Again: "The diseases which I should especially like to have classed in the same group with croupous pneumonia are articular rheumatism and epidemic cerebro-spinal meningitis. These three diseases are undoubtedly non-contagious either directly or indirectly, and should be referred to the category of malarial infections."

Having shown that there are comprehended under the term pneumonia conditions different entirely in their nature, the practice pursued, to be successful, cannot be uniform—each case must have a treatment adapted to its character. Should the temperature take a very high range,—105° F.,

or over,—there can be no doubt that antipyretic measures are imperatively demanded to counteract dangerous effects upon the brain. The material selected must sometimes be chosen with reference to the conveniences and facilities at hand. Cold water is doubtless very efficient and suitable, if the physician can exercise proper supervision. With antipyrin and antifebrin my experience is limited; but quinia did me good service long before these substances were made known. My record of its use as an antipyretic in typhoid fever² in the year 1862, states that the fever daily declined under its use, as evinced by an amelioration of all the symptoms, the reduction in the number of heart-beats per minute being especially noticeable for several days in succession. This was prior to the general use of the fever thermometer. The disastrous effects of high temperatures on the brain and nervous system are shown by the convulsions of children, which are often directly traceable to paroxysm of fever. The case of pneumonia, detailed by Professor Pepper, in the first number of the current volume of the REPORTER, is one which fully illustrates these views. I quote, italicizing what I wish to call special notice to:

"F. C., a boy aged three and a half years, . . . in the fall (1885) had a violent attack of dysentery, which was ushered in with high fever (105°), and a fully developed convulsion. He made a good recovery . . . returning to Philadelphia from the sea-shore, in October, 1886, in unusually good condition. In November, he began to exhibit catarrhal symptoms, affecting in a slight degree the respiratory and digestive mucous membrane. He was confined to the house for at least two weeks prior to the onset of the attack now to be described, which occurred on December 2d.

"He was noticed to become suddenly very hot, and, at the same time, to grow dull and heavy. I was summoned hastily, but before I reached the house he had a severe convulsion. The rectal temperature was 107°. After the convulsion he was heavy and dull, and almost unconscious, but this state was disturbed by recurrence of severe convulsions at short intervals. He was immediately placed in a tepid bath, the temperature of the water being reduced until it was quite cool, and until the temperature fell to 104°. It rose again almost immediately after his removal from the bath, and the repetition of this measure did not produce any more

¹ *Art. Croupous Pneumonia, Ziemssen's Cyclop.*, v., p. 143.

² New Jersey Medical Soc. Report for 1863.

lasting effect. Antipyrin was then given in the dose of three grains, repeated in three hours. The effect was very prompt and satisfactory. The temperature fell to $103\frac{1}{2}^{\circ}$, the skin became moist and relaxed, and the rectal temperature did not rise above 105° for several days."

A treatment that so evidently averted the danger of immediate death, can but receive our hearty commendation. This for the excessive temperature. For the development in the lungs, my views are elsewhere made known.¹

It will greatly simplify our notions of pneumonia, and make our treatment of it much more satisfactory, if we shall be able to relegate the affection, which I have heretofore described as adynamic pneumonia, to the category of infectious fevers, with a pneumonic development; and the disorder treated by Doctor Maxwell to that of the pernicious fevers, with a pulmonary complication. The following quoted from Juergensen,² on the malarial complication of croupous pneumonia will, I am sure, be interesting and timely.³ "There are two forms of this complication which must be distinguished from each other—a simple co-existence of croupous pneumonia and intermittent fever, and a malarial infection localizing itself in the lungs. In the first case there is a mere complication, the symptoms run their course alongside of each other, and when the intermittent fever is cured by quinine, the pneumonia, which still remains, continues its progress undisturbed. *The malarial infection localizing itself in the lungs exhibits itself, according to Grisolle, as either intermittent or remittent pneumonia, and both belong to the group of pernicious forms.* Thus, cases are characterized by the occurrence of pain in the side and bloody expectoration, coincident with the ushering in of the attack by an unusually severe and long-continued chill. At the same time, the physical examination reveals dulness of the percussion note, and fine, dry, abundant crepitant râles sometimes mixed with blowing sounds. These local symptoms continue through the hot stage of the intermittent, and then quietly subside, together with the pneumonia, during the profuse sweating, at least in the first and second attacks. Occasionally, however, a slight amount of pulmonary lesion can be detected even during

the apyrexia, which is said to be complete. The tertian and quotidian types are more frequent than the quartan. If the return of the attacks is not prevented, the patients commonly die in the third or fourth paroxysm; in many cases both lungs are affected, and severe brain symptoms are also present. The remittent form is distinguished from the intermittent by the fact that during the remission a resolution of the local process does not always take place. . . . In both forms the whole disease, including the pulmonary affection, may be controlled, and perfect health restored by quinine."

Juergensen adds this pithy statement: "It appears to be fairly well proved that a severe disease of the lungs may be produced by malarial poison, but *it is by no means demonstrated that this affection is croupous pneumonia.*"

Let us not, therefore, be discouraged at the divergence of views respecting this disease. Observations made in the true spirit, and interchange of opinions honestly expressed and courteously maintained, must sooner or later establish the truth. In medicine, as in other realms of knowledge, "we know in part"; and if "we prophecy in part," we shall be in a happy state of mind to enjoy the inauguration of the time when

"Error wounded writhes in pain,
And dies among his worshippers."

PHLYCTENULAR OPHTHALMIA.

BY EDWARD JACKSON, M. D.

Adjunct Professor of Diseases of the Eye in the Philadelphia Polyclinic.

The acute inflammations of the eye are apt to demand the attention of the general practitioner, and phlyctenular inflammation of the conjunctiva and cornea is so common and so generally amenable to proper treatment, that it is of especial interest and importance. The phlyctenule, which is the lesion characterizing the affection, may be single or multiple, and situated on either the scleral portion of the conjunctiva or the cornea, or both, the corneal margin of the conjunctiva being a favorite location. It consists of a swelling two or three millimeters in diameter, due to semi-solid exudation under the epithelial layer, and appears rather suddenly, with a good deal of stinging and smarting in the eye. Generally, after two or three days the centre breaks down, forming a superficial ulcer. The hyperemia is mainly confined to the immediate neighborhood of the

¹ Art. on Catarrhal Pneumonia, *Phil. Med. Times*, Vol. XII., p. 887. Art. on Blistering the Surface in Internal Inflammations, *idem*, Vol. XVII., p. 623.

² Ziemssen's Cyclopædia, Vol. V., p. 121.

³ The italics are mine.

phlyctenule; but in the conjunctiva lining the lids, the vessels will almost always be found enlarged and tortuous, while the tissue between them is transparent and free from the exudation which marks catarrhal and purulent conjunctivitis. There is an excessive secretion of, sometimes acrid, tears, but very little muco-purulent discharge. There is usually a strong tendency to keep the eyes tightly closed, and to avoid light; but this does not start as a true photophobia. The morbid irritation primarily involves the nerve filaments of the fifth and not of the optic nerve, and the patient may as violently resist the opening of the eye in a darkened room as in a bright light. Still, by the continuous avoidance of light, in many cases, a true photophobia is presently developed.

Commonly but one eye is attacked at a time; and if both suffer, as they are eventually apt to do if repeated attacks occur, one is generally much worse than the other. The disease is one of childhood and youth. Of 32 cases seen during the last year in private practice and in the eye service of the Polyclinic, 11 were five years of age or less, 10 were between five and ten, 5 between ten and fifteen, and 5 between fifteen and twenty. In adults but a single case occurred, which was in a woman of twenty-eight. Of these cases 13 were in males, 19 in females. The writer is inclined to think that the disease is generally more liable to affect girls, though such a tendency has not been noted by others. Children of pure or mixed negro blood are especially subject to it.

Phlyctenular ophthalmia depends most obviously upon some diathesis or cachexia, some general vice of nutrition. It is a common sequel of the acute inflammatory diseases of childhood. It has long been regarded as a manifestation of "scrofula," and Arlt in his last work retains for it the designation conjunctivitis scrofulosa. It is most frequent among the poorer classes, especially in towns and cities; but, like the constitutional condition upon which it springs up, it is by no means strictly confined to them. Owing to this dependence on general disorders of nutrition, difficult or often incapable of complete removal, relapses and repeated attacks are very common.

When the phlyctenules are confined to the conjunctiva, the disease is properly a phlyctenular conjunctivitis, and usually responds promptly to treatment; recovery occurring within one or two weeks, without great inconvenience, or serious danger to vision. When, however, some or all of the

phlyctenules are situated on the cornea, as was the case in 14 of the patients above referred to, it is much more obstinate; and there is great danger of permanent impairment of vision through alterations in the shape or transparency of the cornea, and the danger increases with the extent of corneal surface involved, and its nearness to the centre of the cornea. If the ulceration extend much in front of the pupil, some impairment of sight is inevitable; and often when this region is not directly invaded, considerable astigmatism may result from the cicatrization of other parts, and as astigmatism from this cause is more or less irregular it cannot be wholly relieved by glasses.

When the phlyctenule is situated on the cornea it cannot be immediately surrounded with hyperemia; but the redness is manifested in the enlargement of the nearest conjunctival vessel, and of that net-work of extremely small vessels which surrounds the margin of the cornea, whose hyperemia occasions the so-called peri-corneal zone. Sometimes this zone of redness entirely surrounds the cornea, usually it is most marked in the part nearest the phlyctenule, and often it is limited to that locality. If the case is at all obstinate the nearest conjunctival vessels are very apt to send out branches, which extend upon the surface of the cornea to the ulcer. Thus is formed the opaque vascular band, indicated by the terms fascicular, or superficial vascular keratitis.

The differential diagnosis of the disease is not usually difficult if attention is given to the great irritability of the eye, with the absence of purulent discharge, or general visible lesions, the localization of the hyperemia and the tendency to recurrence of the attacks.

In the *treatment*, bandaging of the eye is to be avoided unless there seems danger of an ulcer perforating the corner. Blisters, setons, and other such counter (?) irritants are to be mentioned only for condemnation. It is usually best to begin by placing the eye under a mydriatic. A single drop of

R Atropiæ sulphat.....gr. j.
Aq. destillat.....f ʒij.

or the same quantity of

R Duboisiiæ sulphat.....gr. ss.
Aq. destillat.....f ʒij.

may be instilled three times a day. In the lighter cases of conjunctivitis this is not necessary. But in the severer cases, and in all which involve the cornea, it should be done. Although in this affection we need

not invoke the greatest power of the mydriatic, I prefer the above solutions in small quantity, to weaker ones, more profusely applied, because the increased and excessive lachrymation, provoked by even the gentlest interference with such an eye, causes the immediate dilution, and to some extent, washing away of the solution applied. In mild cases which require no mydriatic, and as an addition to the more severe,

℞ Acid. boric. gr. x.
Aq. camphoræ. ℥j.

may be freely instilled every three hours.

A most important part of the local treatment is the dusting of calomel upon the open ulcers, or the application daily of an ointment containing:

℞ Hydrarg. oxid. flav. gr. j.
Petrolatum. ℥j.

placing it on the inside of the lower lid, and gently rubbing the lids over the globe until it is diffused throughout the conjunctival sac. The proportion of mercury in this ointment may sometimes with advantage be doubled.

Most cases of phlyctenular conjunctivitis can be cured by local treatment alone, and often in a very few days. But to effect a cure where the cornea is involved, and to prevent a repetition of the attack, it is necessary to bring influences to bear upon the general processes of nutrition. In the first place, the child should secure several hours of out-door life every day. To accomplish this it is necessary to control the photophobia. It may be lessened by cold-douching of the eye-lids, or applications to them of *very hot* fomentations, for five minutes at a time. The mydriatic allays it very much, and a broad-brimmed hat or dark glasses may be worn. Everything should be done to induce the child to overcome it. Next after out-door life, with suitable clothing, and a proper temperature when in the house, the alimentary canal demands attention. In most cases errors of diet have to be corrected; and a mild purge is often very beneficial. After all these matters have been attended to, cod liver oil, reconstructives, tonics and alteratives may be thought of. Iron is most frequently indicated, and the syrup of the iodide finds here one of its best applications. It is well to commence with one drop for each year of the patient's age, given with plenty of water upon an empty stomach, three times a day; and to rapidly increase the dose until its therapeutic influence is manifest, or indications of gastrointestinal irritation are noted. Constitu-

tional treatment should be continued a considerable time after the attack has subsided.

The resulting astigmatism of phlyctenular keratitis usually continues to alter in degree for some months, during which time close eye-work should be avoided. When it has assumed its permanent condition, it should be carefully studied, both with and without a mydriatic; and, in so far as it is capable of it, corrected by the appropriate lenses.

HYSTERICAL BLOOD-SPITTING.

BY STANLEY M. WARD, M. D., ELLENVILLE,
N. Y.

In an article on Hysteria which I had the pleasure of preparing for the REPORTER (Vol. LII, No. 15) I referred incidentally to a case of hysterical blood-spitting which I had then had under observation for two years. I propose now to give a complete history of this case from April, 1883, the date of my first visit, to February, 1886, when I last saw her, prefacing it with the following note from her mother written under date of May 23, 1887: "Gertie has had no attack of bleeding since last September and it was not bad then. She does not complain of her side troubling her very much and her nervousness is nearly gone. She can eat more of a variety, but vomits at times. She is now attending school in Brooklyn."

April 18, 1883, saw Gertie B., aged 17, decided blonde. Her family history is good.

The patient was healthy until 1882, when she fell and struck her side against a stump. This blow was followed immediately by vomiting, vertigo and insensibility, and later by the appearance of a tumor(?). In a few days she regained her usual health. On April 15, 1883, after some extra exertion and mental excitement, she had a severe attack of epistaxis accompanied by vomiting and followed by diarrhoea. On April 18, she suffered with diarrhoea and was so weak that her discharges were received in napkins. She was given sub-nitrate of bismuth and a little brandy occasionally. At 8 A. M., the 19th, Dr. J. J. Ward saw her; she had no diarrhoea but was vomiting continually. The emesis was not brought on by food or medicine. The matter ejected was a darkish green liquid, and sometimes contained shreds which resembled mucus.

Under the use of small pieces of ice, minute doses of calomel, bismuth, with lime water, her symptoms improved by next morning; but in the afternoon they returned

with greater severity than before. I saw her at 11 P. M. Administered nutrient enemata every four hours and interdicted all medication and food by the mouth. On April 24, I began giving her small quantities of food by the mouth instead, and three times daily she had two drops of Fowler's solution of arsenic, combined with three drops of the tincture of *nux vomica*. She complained bitterly of hunger on the occasion of my last visit on the above date.

It was not easy to make out the exact nature of the attack, but, whatever the condition of the alimentary canal, it was relieved only by giving the stomach absolute rest.

May 10, sixteen days from my last visit, the patient was again attacked with diarrhœa. I found her limping around the house favoring the left leg by throwing most of her weight on the right. She said the tumor, above referred to, had pained her considerably of late but was now much smaller than formerly. She did not wish to have it examined. I prescribed a simple astringent and left her. At 11 P. M. I was summoned with the news that the girl was vomiting blood. About noon she had something warm in her mouth and spat it out, to find it blood. She had repeated the act several times during the afternoon and evening, and had fainted once after raising a large quantity of blood. There was pain over the "tumor" and in the epigastrium. She spat the blood and did not vomit it. There were no attempts at emesis except at long intervals. The blood was not aerated and it did not show any signs of having been acted on by the gastric juice. Her lungs were acting well. A close inspection of the fauces and posterior nasal passages convinced me that the source of the blood was not there.

She continued to spit blood thus until midnight of May 11th. The longest period between the attacks was half an hour, the shortest ten minutes. I have no means of knowing the quantity. At this time, midnight, she had some localized peritonitis, pain in the back, cold extremities and conjunctivitis, pulse 120, temperature 96°, no movement of the bowels had occurred in six hours. There had been administered morphia in small doses, ergot and ergotine, nitrate of silver, oxide of zinc, hamamelis, and Monsels' solution of iron. She slept for three hours. On awakening she soon began vomiting. The matter ejected was a greenish liquid, of a horrible odor and unmixed with blood. Great relief was experienced after vomiting, although there was severe

pain before and during the act. All medication by the mouth, except small doses of morphine, were discontinued and nutrient enemata were given every six hours. The vomiting and nausea were almost constant until the night of the 15th. The enemata failed to be retained on the 13th and were discontinued. On this day she began to complain of numbness, and of tingling sensations in various parts of the body, and also to tell outrageous lies. Bowels moved copiously on the 13th and 14th, the stools being semi-fluid and resembling decomposed blood. They were very offensive. The vomited matter was a darkish-green liquid, emitting a horrible odor. May 16, she is vomiting at long intervals. Is much brighter. Is retaining a half teaspoonful of Murdock's food every three hours given with a little brandy, and at night she takes an eighth of a grain of morphine.

May 19, Dr. J. J. Ward and I saw her. Complains of a sense of fullness in the epigastrium and is very hungry. Has vomited nothing since the night of May 16. Bowels confined since May 15. She was kept gently under the influence of morphine and a pill of aloin, gr. 1-6; strychnia, gr. 1-20; and belladonna, gr. 1-8, was exhibited every six hours. After taking three of these pills she had several watery passages. She was given one drop of Fowler's solution of arsenic every four hours. Beef tea and milk were also allowed.

May 21. She still complains of hunger. Allowed a little more latitude in eating. May 25. Is around the house. Limp badly while walking. Has no pain. Appetite voracious. May 29. Tendency towards diarrhœa. Otherwise doing nicely. Stopped arsenic and gave opium and bismuth p. r. n. June 6. Severe diarrhœa. No appetite. She has passed several restless nights since my last visit. Refuses to take any more of the Murdock's food, as it sickens her. She was ordered suppositories of opium and tannin, and by the mouth is to have six teaspoonfuls of elixir of gentian and iron during the twenty-four hours.

June 8. Limp badly. Bowels move three times daily, even while taking the astringent suppositories. Intense conjunctivitis. She says that blood oozes from her eyelids at times. Is not emaciated in the least. On the left side I felt a hardened mass, which was painful on pressure. Patient has spit up blood four times to-day. Ordered her to bed. Murdock's food with milk thrice daily, a pill of ergotine and opium thrice a day, and also a tonic pill thrice daily. On the 10th

I decreased the opium, as it produced drowsiness.

June 15. Patient is gaining in flesh; has had no bleeding in a week; walks more erect, and thinks the "tumor" is diminishing; complains of headache and pain in the back. The tonic pills were discontinued and dialysed iron substituted. Continued Muddock's food with milk, a pill of ergotine and opium at night, and twice daily bismuth and opium, as there was a tendency to diarrhoea.

June 16. On June 16th substituted suppositories of gallic acid, tannin, and opium for bismuth mixture. The diarrhoea was lessened under this treatment and her bowels moved naturally on June 20th.

June 22. Patient complains of excruciating pain in the top of her head and of aching limbs. Her mother states that there is oedema of both ankles at times. Her last menstrual flow was scanty. The dialysed iron was continued and three grains of quinine given every three hours. She refused to allow an examination of her side, but said that the "tumor" was gone.

June 23. Began bleeding from the mouth to-day. Menstruation also commenced. Dr. J. J. Ward saw her. He failed to find any evidence of a "tumor" after carefully examining her side. All former treatment stopped. She had five drops of hamamelis combined with five of ergot every hour, and an occasional pill of morphine, gr. $\frac{1}{4}$, and atropine, gr. $\frac{1}{20}$, both to be continued until symptoms were relieved.

July 6. Note from patient states that the bleeding stopped on the night of June 23d and had not resumed. She had taken four of the atropine and morphine pills in twenty-four hours. Had recommenced the dialysed iron and felt "much improved."

July 29. Her general appearance is indicative of health. She limps somewhat while walking. Bowels move at least twice daily. Appetite capricious and irregular. There is no "tumor," but there is soreness over its former site (?). The treatment was continued.

On July 31st and August 1st, there were copious attacks of epistaxis, but no blood passed this month.

On August 9th she had some hemichorea. The choreic movements stopped on August 12th, and were followed immediately by partial paralysis of the tongue, which lasted a few minutes.

In February, 1886, a sister was married against her wishes. Brought herself into prominence, on the day of the wedding and the night before, by spitting blood again. She bled for three days, and had the same

intense headache and tenderness along the spine. She was treated with the combination of valerian and assafoetida with morphine and atropine, as indicated. This is my last note. The communication received from the patient's mother, already quoted, partially fills the hiatus between that time and the present. It will be observed that the intervals between the attacks of bleeding are lengthening, and it is to be hoped that in time the attacks may cease. I doubt it, however, for as some persons under undue mental or physical excitement suffer from excessive urination or diarrhoea, so I believe my patient will have blood spitting.

I have called this a case of hysterical blood spitting. I may state that such a diagnosis was not arrived at until every possible cause for the hemorrhage had been carefully considered by the consulting physician and myself.

In concluding, I may be allowed to call attention to an extract from an address delivered by M. Auguste Ollivier before the congress at Nancy, an extract which has appeared in several periodicals, but which I cannot find entire. He says hysterical hæmatemesis is too often considered as symptomatic of gastric ulcer, and that "in reality it is a form of local hysteria, with gastralgia accompanied by hemorrhage."

MALIGNANT LYMPHOMA, OR HODGKIN'S DISEASE, WITH PNEUMONIC COMPLICATION.

BY JAMES MACREADY, M.D., MONROE, OHIO.

Aug. 26th, 1885, I was consulted by J. E. L., a farmer aged 50 years, in reference to a general enlargement of the lymphatic glands of the face and neck. The history which he gave was, that during the previous June he noticed a gradual enlargement of the glands in the submaxillary region of each side, the region of each ear and the post cervical region.

The submaxillary glands were the first to enlarge, from whence there was a gradual extension until the post-cervical became involved.

The submaxillary region of each side was occupied by a cluster of glands, five of which on the right side, and four on the left, were each about the size of a hazel-nut. These were the first to enlarge. When the hand was passed over the lateral and post cervical regions, the sensations communicated to it were those of numerous hard globular

bodies, varying in size from small shot to that of a buck-shot lying loosely under the skin. No amount of manipulation caused pain.

His general health was apparently unimpaired.

An examination of the family history showed no hereditary tendency to scrofula or phthisis.

I did not see the patient again until Nov. 28th, 1885. During the interval which had elapsed since Aug. 26th, the glandular enlargement had advanced until, seemingly, each gland had increased in size until it was about twice its size at the former examination.

The face in consequence was hideously deformed. He now complained of a cough and sore throat.

An inspection of the throat showed the tonsils to be enlarged, and the uvula was greatly elongated. Auscultation and percussion revealed no lesions of the lungs, which led me to conclude that the cough resulted from laryngeal irritation by the elongated uvula. There was no history of syphilis; the absence of struma and of a syphilitic history excludes them from the causation of the glandular enlargement.

I was, therefore, led to conclude that I had one of the forms of lymphadenoma to deal with, and whether benign or malignant only time would determine.

The patient's general health at this time was apparently unimpaired. The appetite was good, and nutrition of the various tissues seemingly well performed. His capacity for the performance of labor was as vigorous as formerly. He had not been seriously sick during the past twelve years.

The plan of treatment adopted was, for the relief of the sore throat, the following, to be used as a gargle:

R	Tannin,.....	3 j
	Ammon. muriat.....	3 ij
	Aquæ,.....	f 3 iv
M.		

As a resolvent to subdue the glandular enlargement I gave, tinc. iod. comp. six drops three times a day, and as an external application to the enlarged glands I prescribed:

R	Potass. iod.	3 ij
	Aquæ, ...	f 3 iv
M.		

Each evening before retiring pledgets of cotton saturated with this solution were applied to the enlarged glands, and kept in place by an external covering of rubber cloth.

A favorable experience in the treatment of glandular enlargement of strumous origin, by the constant electric current, induced me to try it in this case.

Each of the largest tumors, on every second or third day, was subjected to electrolysis. An insulated needle attached to the negative pole, was introduced into the gland. The positive pole enveloped in wet sponge was passed over the adjacent tissues, during a period which varied from five to twenty minutes. The time required for thorough electrolysis varied with the quantity of the current that could be used, sometimes only six elements were intensely painful, while at others sixteen elements were well borne. If the cutaneous surface was saturated with the iod. potass. solution, the application of a feeble current was intensely painful.

Each time the electricity was continued until the withdrawal of the needle was followed by an aqueous discharge, untinged by blood. Puncture of a gland without thorough electrolysis was always productive of a flow of blood, which continued until arrested by pressure.

During the latter part of December, this treatment was interrupted by an attack of facial erysipelas. At the expiration of ten days, the patient was again able to visit my office, when the treatment was resumed, and continued through Jan. and Feb. 1886. During the three months that had elapsed since beginning treatment by electricity, there was no perceptible change in the size of the various glands. They rarely became painful after treatment.

On March 7th, he was again attacked by erysipelas, which began at the end of the nose, and spread rapidly until the whole face became involved and enormously swollen.

At the end of a week the erysipelas was under control. The subsidence of the swelling showed the enlargement of the glandular structures to be on the increase, especially in the post-cervical and lateral regions, and extending to and beneath the clavicle. The axillary glands and those in the inguinal regions now began to enlarge rapidly, and soon formed large clusters in those regions.

The advent of the latter enlargements, and their rapid growth, gave to the case an unfavorable aspect.

After recovering from the erysipelas, he did not regain his usual strength, though he was able to return to his business. Anemia now began to be apparent, and the cutaneous surface assumed a tawny, unwashed appearance that contrasted with the former healthy color. When performing labor which re-

quired him to stoop much, he complained of dyspnoea.

The remedies which have been used to this time (March 20) were proving to be unreliable. The iodine treatment was discontinued, and potass. arsenite substituted as follows:

R Liq. potass. arsenitis, ... f 3 ss.
 Aqueæ. f 3 iij ss.

M.

Of this a tablespoonful was taken three times a day. The electricity was used as often as he was able to visit my office.

April 3, he visited my office for treatment. At this visit there was evident subsidence of the glandular enlargement in all parts of the neck; but those in the axillary and inguinal regions were unaffected. This was the last time electricity was applied.

April 12, I was summoned to visit him at his residence. I found him much exhausted and unable to leave his bed. He informed me that he had been having a chill each day at about 10 A. M., during the three preceding days.

My visit was made at 10 A. M. His temperature now was 102°, pulse 90. Complained of pain in the right subscapular region. Auscultation over this region revealed crepitation. Coughed some, but this was not annoying. The urinary secretion was abundant and highly colored—almost blood-red. Its specific gravity was 1030. The cervical glands were much diminished in size. Six days after this the glandular enlargement in the different cervical regions had so far diminished that it was necessary to closely inspect the parts involved to detect any enlargement. Gradually the crepitant râles gave place to tubular respiration, while percussion over the right lung elicited the signs which denoted consolidation over the whole right lung. The urinary secretion continued to be abundant, and maintained a specific gravity of 1030 as long as I was able to secure it for examination. Its color was blood-red. A portion of the coloring matter subsided to the bottom of the chamber, and stained the surface a deep pink color. Though it looked as if it contained blood, no red corpuscles were detected by the aid of the microscope. Analysis showed the coloring to be *free urohæmatin*, which, when it appears in the urine in a free state, or in considerable quantity, is of great clinical importance, denoting rapid destruction of red blood globules, and excessive retrogressive tissue metamorphosis. Accurate analysis will almost always discover *urohæmatin* in the urine in small quantities. It is a normal ex-

cretion, resulting from blood corpuscles whose term of life has ceased, and as dead matter are removed, that others which are being constantly called into existence may take their place. "With every respiratory act, with every pulsation of the heart, thousands of blood corpuscles are destroyed and thousands reappear."

April 18, the patient became delirious.

April 19, the mental condition alternated between delirium and semi-coma. He seldom coughed. Up to the past two days he was able to move himself over the bed, and to assume any position desired of him. He now has to be assisted to turn in the bed, and passes his urine involuntarily. Death occurred April 20.

Seventy-two hours after death an autopsy was held. This was delayed to secure the consent of absent relatives. The body had been embalmed by the undertaker, who had introduced his embalming fluid into the brachial artery, without removing any of the fluids of the body.

There were present at the examination Dr. T. A. Dickey, of Middletown, O., to whom I am indebted for assistance in the work, and Dr. August Eckert, of Trenton, O.

The deceased, when in health, had possessed a fair amount of muscular development, and adipose tissue. Each of these had become greatly attenuated. Before opening the body, inspection showed the glands in the axilla and those of the groin to be enlarged. Only the abdomen and thorax were opened. The contents of the abdomen were first inspected. The right lobe of the liver was enlarged in all directions, its inferior margin extending not less than two and one half inches below the border of the ribs. It was indurated, but not nodulated. The left, or transverse lobe, was apparently atrophied, its border scarcely reaching to the median line. The spleen seemed to be uniformly enlarged in all directions, probably three times its normal size, and was quite hard to the touch. Beneath the capsule there was seen a whitish or grayish deposit, which, when the fingers were rubbed over the capsule, communicated a sensation of roughness. The stomach and intestines were normal in appearance, except a general enlargement of the lymphatic glands of each. The glands along the greater and lesser curvature of the stomach, and those of the large and small intestines and mesentery, were all in a state of enlargement, and varied in size from that of a hazel-nut to that of a large hickory-nut. The deep lymphatic glands of the abdomen and pelvis were all hypertrophied. So far as

the unaided eye could determine, the pancreas and kidneys were not diseased.

The left lung was slightly congested, evidently hypostatic. The right lung was hepatized in all its parts, and was of a dark gray color. When cut into, serum, and not blood, exuded. Small deposits of calcareous matter were found in this lung. Between the pleura pulmonalis and pleura costalis there were extensive adhesions of recent origin. The pericardium contained only a small amount of fluid. The heart was normal in size, but its muscular tissue was softened, and was easily broken up.

The bronchial glands were enormously enlarged. Some of them were in a state of softening, the capsule breaking easily and giving exit to a variously colored matter, resembling lard with coloring matter mixed with it. Others contained calcareous concretions. From the degenerations which were taking place in the glands they were probably the first to enlarge. The cadaver contained but little blood—much less than usual.

I think there can be no doubt that the immediate cause of death was pneumonia. How long life would have continued, had not this complication intervened, is a question on which we can only conjecture. The pathological anatomy, except the pneumonia, is that of *malignant lymphoma*, or Hodgkin's disease. The literature relating to the latter disease shows it to generally end fatally. Gower, who writes the article relating to it, in *Quain*, says: "Where the disease is widespread or the local growths considerable in size, a fatal termination is almost certain." This author designates it by the term, *lymphadenoma*.

Birsch-Hirschfeld says: "In some cases it lasts only from two to six months; in the majority, about one year; cases of over three years' duration are very rare."¹

This writer is probably the author of the term *malignant lymphoma*. He seems to doubt that any case has recovered. He refers to the cases treated by Winnewarter, and at the clinic of Billroth, by arsenic.

In the *Canada Med. and Surg. Journal* for July, 1883, two cases are reported, which were treated by arsenic, and decidedly benefitted, but not cured. In the case which I have reported the glandular enlargement on the neck and face continued to increase from August 26, to Nov. 28, 1885. On the last date treatment by electricity was commenced.

During the three months following there was no perceptible increase in the size of the

glands. After the second attack of erysipelas a rapid growth began.

March 20, Fowler's solution was first administered. April 3, a diminution in size was perceptible in those regions to which electricity had been applied. All those glands had not been punctured by the electric needle; only the largest ones. But those thus treated did not disappear faster than the adjacent glands. All the glands in those regions began a retrogressive movement about the same time. Did electrolysis of one gland influence adjacent glands? is a question not without interest. When we reflect that no enlargements except those of the face and neck were diminished, and that in other localities, where they were accessible to the touch, the glands continued to grow, it would seem that the change was affected not by either electricity or Fowler's solution alone, but by a combination of the two, the former being *catalytic* and the latter *eutrophic*.

While we are ignorant of the essential pathology of a disease, all treatment must, of necessity, be empirical. All we know of this disease is, that certain states of hematosis accompany or follow the glandular enlargement. But whether the cause is in the glands, the blood, or the nervous supply of the glands, we are ignorant.

If the empirical administration of arsenic leads to success in treatment—and there is evidence that this has been partially attained—cannot this be regarded as presumptive evidence that in the ganglionic nervous system is the *fons et origo mali*?

ABORTIVE TREATMENT OF TYPHOID FEVER.

BY F. MCTAGGART, M. D., OF SAN FRANCISCO,
CALIFORNIA.

Much has been said relative to the abortion or abbreviation of the course of enteric fever. Remedies of only ordinary utility have been vaunted as of special importance in this direction. New agents have been put forward with such praise that although prefaced by the writer with the expression of a non-belief in specifics, their overrating has given to them no other color than that of admirable specifics, and led to such reliance upon their employment as to produce much mischief. Drugs enthusiastically presented to-day are rejected to-morrow. A course of treatment plausibly advanced in the medical journals by some confident experimenter as of unwonted value, is denounced at once by

¹ Ziemssen, Vol. xvi. p. 844.

medical authority as of but little utility, or of no value whatever. Valued results from scientific investigation by eminent men in the profession are not unfrequently examined by those of equal prominence, only to be consigned to oblivion. What one famous teacher has found of paramount importance in abbreviating the duration of the disease, another absolutely fails to find of any virtue. This clashing of opinions and disagreement of conclusions opens such a field of doubt and uncertainty as to the nature and virtue of medicinal agents that the tendency is to such skepticism in medicine that the most palpable facts receive but passing attention. The conviction that medicines can only modify or mitigate violent symptoms, deters one from giving results of his own experience, however successful they may be.

It is, therefore, with hesitancy that I suggest a method of treatment which I have found to act as an abortive—in some measure at least—of this disease.

As I regard the cause of typhoid fever to be a germ which permeates the system through the breathing passage, and deranges the whole alimentary canal, I begin by charging the atmosphere of the patient's room with what I conceive to be antagonistic to the previously inhaled source of the disease; as spirits of turpentine and liq. sodii chlorinati are deadly to animal and vegetable parasites, the air is well charged with these. The former is not only destructive to disease germs, but is, when sprinkled about the room, productive of ozone. Be this as it may, a room thus deodorized is better for both patient and attendants. Next, whenever the strength of the patient warrants the procedure, I wash out the stomach with the following preparation, after cleansing with warm charcoal water:

R. Liq. sodii chlorinati.....f 3 ij
Vini gallici.....f 3 j
Aque destil. q. s. ad.....O j

M.

The process does so much good and causes so little fatigue, that I withhold it only when life is threatened, or the disturbance is but slight. The washing having been thoroughly but gently done, I give enemata of charcoal water, well charged with the charcoal, and follow the dejections with enemata of sweet oil, to which has been added naphthalin, 15 to 20 grains to the pint. Subsequently the bladder is washed with warm water holding in solution two drachms of boracic acid to the pint, and one thirtieth of a grain of biniodide mercury is given every two hours. If diarrhea is present the mercury

is not given; if it comes on the mercury is withheld, and naphthalin is administered in from five to seven grain doses every two hours. With an irritable stomach the initial dose should be smaller, till a tolerance of the medicine is established. Failing in this, I select benzoate of soda with ergot, and employ strychnine during the whole course of the disease.

For reducing fever I have found an excellent agent in the nitrate of ammonia. It was suggested to me by Dr. A. B. Stuart, of Santa Rosa, Cal., who with much show of reason ascribes to it still other virtues in the treatment of typhoid fever. It should not be employed with the mercury, nor with Labarraque's solution. Frequent washings of the stomach are not necessary as the first has already reached the seat of the disease so far as washing the stomach can; and subsequent morbid deposits are dislodged with sufficient frequency by the washing every second or third day. As feculent matter readily accumulates in the lower bowel, the enemata of naphthalin and olive oil are repeated once or twice a day, not forgetting the previous cleansing with charcoal water. Cleansing the bladder or medicating it with the boracic acid solution, is done as often as the condition of the urine indicates. Epistaxis, if serious, may be controlled at once by forcing tincture of benzoin well up the nostril with a small syringe. Injections of equal parts of milk and spts. of turpentine, thrown up well, control hemorrhage from the lower bowel, and act favorably in ulceration. But, as it is uncertain whence hemorrhage proceeds, I give by the mouth benzoate of soda with fluid extract of ergot, and Bartholow's pill of sulphate of copper, quinine and morphine alternately.

Now, while placing some reliance upon the medication by the mouth here presented, I attribute the abbreviation of the disease chiefly to the other mode of treatment. Not that the adoption of one to the exclusion of the other would prove efficient, but my experience leads me to believe that both combined will abort typhoid fever, if taken at the beginning, and at a later period would be attended with great success.

—A recent estimate shows that about one-fourth of the population of New York, Boston and London receive free treatment at the medical clinics; in Philadelphia, one-fifth, and in Liverpool over one-half the population.

REPORTS OF SOCIETIES.

THE CLINICAL SOCIETY OF
MARYLAND.*Stated Meeting, held May 5, 1887.*

DR. HIRAM WOODS read a paper entitled,
Review of Some Recent Literature on Chloroform and Ether,

the concluding part of which is as follows :

DR. SAYRE allows his patients to inhale only air which has passed through chloroform. He produces narcosis by giving from 15 to 30 drops. While I am unfamiliar with the inhaler used by Dr. Sayre, there has been in constant use at the Presbyterian Eye Hospital for some months an inhaler constructed on the same principle. All inspired air passes through a small sponge moistened with chloroform. I have seen chloroform used almost daily at the hospital for the past five years by the old towel-cone method. The first time that I used this inhaler, I was surprised to find my patient narcotized by about 20 drops of chloroform. Has this method any advantages over the old plan, or is it more dangerous? I have already given Dr. Sayre's opinion that it is safer because more chloroform must be given by the old method to produce anæsthesia, and there is more danger of the patient's system becoming saturated with it. I can hardly think that Dr. Sayre means to say that by the old plan a patient can inhale one atmosphere of pure air and another of chloroform. The inspired atmosphere is a *chloroform* atmosphere of greater or less saturation. There are several factors which will determine the degree of chloroform saturation. The most important are the amount of chloroform poured on the towel cone, the distance it is held from the patient's face, and whether the anæsthetizer moves it about or keeps it still. Chloroform vapor has a greater specific gravity than air; consequently it displaces air downwards. The farther it is held above the patient's face the more air it must displace, and hence, the more of its own antidote will it meet before it is inhaled. Hence it will be weaker when inhaled and have less physiological effect. The same course of reasoning will apply to moving it about and bringing it into contact with a greater amount of air, and to the amount poured on the towel. Rarely less than 3ii to 3ss of chloroform are poured on the towel. If this is held *still* an inch or so from the

patient's nose and mouth, it is easily seen how he may be compelled to breathe an atmosphere which is almost pure chloroform, and so the system may become, as Dr. Sayre says, saturated with the anæsthetic. I do not, however, believe there is as great danger of saturating the system by the old method as Dr. Sayre implies. If the towel-cone is held at a proper distance (four to six inches) from the face and moved to and fro, undoubtedly more chloroform is *used* in producing narcosis. The excess has little, if any physiological effect. Air is its antidote, and it is the admixture with air which necessitates the extra amount of chloroform. The chloroform vapor must be absorbed before it affects *any* physiological function, and the air antagonizes it *before* it is absorbed. Hence, its action is modified all along the line, and if the large amount of air postpones narcosis, it must also lessen the influence of chloroform on the rest of the system. The advantage of the inhaler lies in the *certainty* which it gives as to distance and dose. Even a careful man may occasionally hold his towel-cone with its 3ii of chloroform very near the patient's nose, and force him to breathe an atmosphere which can kill him. The danger of this is reduced to the minimum by the inhaler. We have seen that by *any* method of inhalation it is only a question of the degree of chloroform *saturation*. A definite amount (15 drops), poured on a sponge through which the same quantity of air passes at all times, gives the patient a *fixed* and *definite dose*, which can be repeated or not, according to the effect it may have. "If," as Dr. Sayre says, "any peculiar disposition or some other unknown cause" interferes with heart action, this small amount may easily be eliminated, and we have not given an unknown overdose.

A word may be said about the value of statistics. Dr. Weir based his defence of ether largely on the statistical argument. Dr. Gerster, on the other hand, would not admit its value because it is impossible to get all the facts. He knew of *five* ether deaths in one hospital which had never been reported. As to the contradictory evidence of statistics, there was a good example at the very meeting of the New York Academy at which Dr. Gerster's paper was read. Dr. Weir reported 1 death in 2158 cases in defence of ether. Dr. Knapp, also in defence of ether, reported from his own practice 3000 cases of chloroform anæsthesia and no accident. In Ashhurst's Surgery, Prof. Chisolm is quoted as having collected, up to 1877, 250,000 chloroform cases with 12

deaths, or 1 in 20,834. From other sources the average is put to be nearly one death in 23,000 from ether, and one in 2800 from chloroform. The latter is generally supposed to be near the truth. Part of the bad showing for chloroform is to be explained by the diligent search which is made for chloroform deaths, the readiness with which the blame is put on chloroform, and the equally great reluctance to blame ether if anything else can be found as a scapegoat.

Again, many deaths are unquestionably due to faulty administration. But this of itself is something of an argument for ether. It takes *time* to get *experience*, and comparatively few *young* men have a chance to get instruction in a hospital where chloroform is habitually used. Hence an anæsthetic which is "not so inexorably followed by disaster" if badly given, or improperly selected, is to be preferred for general use.

In estimating the value of statistics, doubt is sometimes thrown on the cases furnished by the eye surgeon on the ground that he does not have to use much chloroform in his operations. If the *Medical News* is correct in its interpretation of Dr. Knapp's "primary anæsthesia" (*i. e.*, "before profound narcosis"), his remarks would seem to give support to this assertion. I think, however, that Dr. Knapp means the *first profound* narcosis which is induced. In other words, that he has seldom to renew the anæsthesia on account of his patient waking up. It is a common thing to see the arms drop to the sides, and *apparently* total relaxation, while the slightest touch of the cornea will be followed by spasmodic closure of the lids. With the exception of the rectum and female genital organs, operations on the eye probably require deeper anæsthesia than those on any other part of the body. The chloroform deaths which are absolutely unavoidable are those which come from heart failure. These usually occur *early in the anæsthesia*; either during the stage of muscular rigidity or at the first appearance of relaxation. The eye-surgeon is as apt to have these as any one. He does not, however, run the risks of prolonged anæsthesia which the general surgeon does. These risks I honestly believe depend, as a rule, more on the anæsthetizer than on the anæsthetic. Even if ether be used, its primary effect of stimulation soon gives way to its secondary effect of sedation as the *dose* is increased, and it has to be given with extreme care. The deaths in *prolonged anæsthesia* do not generally occur *suddenly*, but slowly from embarrassment of the respiration and gradual failure of the heart. Important

factors which must determine the result in such cases of collapse are the ability of the anæsthetizer to detect the first and slightest signs of danger, and the character and promptness of the means which are used for resuscitation.

In conclusion a few words may not be inadmissible on the preparation of the patient for anæsthesia and the treatment of collapse. We have seen that with both ether and chloroform there is danger of sudden death from heart paralysis. To sustain the heart over the period of anæsthetic depression is the problem. The oldest and most common practice is to give from $\frac{3}{4}$ ss to $\frac{3}{4}$ i of whiskey twenty minutes to half an hour before anæsthetization. Objection has been made that the secondary effects of alcohol are depressing. Unless the operation be a very long one, this is hardly a strong argument against its use, because the anæsthetic is administered during the stage of stimulation. More forcible objections are (1), that the whiskey is given by the stomach and may produce vomiting if it is not all absorbed, and (2) that it may not be absorbed rapidly enough to have effect. To overcome these, we want something which will stimulate the heart and yet will not have to enter the stomach. Such an agent many surgeons think is found in morphia. Its primary effect in small doses subcutaneously is to stimulate the heart. Then again its sedative secondary action helps the anæsthetic, of which a smaller quantity has to be given and largely prevents the vomiting and suffering which is incidental upon the recovery from an anæsthetic. To the morphia (gr. $\frac{1}{2}$ to $\frac{1}{4}$) a small amount ($\frac{1}{16}$ gr. to $\frac{1}{8}$ gr.) of atropia is added. An editorial in the *Medical News*, Vol. XLI., No. 12, explains the use of atropia by quoting the demonstration of Vulpian: "The excitability of the pneumogastric is increased by anæsthetic agents—whence the vomiting and sometimes cardiac arrest. Morphine, while it increases the anæsthetic action, does not to any considerable extent lessen the effect on the pneumogastric nerve; but atropine by removing the inhibition exerted by the vagus, removes the most important source of danger." There is abundance of clinical evidence to support the administration of morphine and atropia before the administration of anæsthetics. It seems to accomplish all that alcohol can, and to do more: prolong anæsthesia and lessen the danger of vomiting.

There are only one or two points in reference to collapse to which I would allude. One is that the best evidences of approach

ing trouble are to be gotten from the condition of the respiration, the action of the pupil and the complexion. If the first warning comes through the pulse the trouble is usually one for which we can do little or nothing. If the heart once stops, it is generally for good. The best and indeed only treatment for heart failure of this kind is the administration of a heart stimulant before anæsthetization is commenced in hopes of preventing collapse altogether. Even then it will sometimes occur although more rarely than if nothing at all is given. I know that there is often a *gradual* weakening of the pulse which portends danger; but this is accompanied by shallow and slow respiration and pallor of the face. These latter usually precede the weakening of the pulse, and should have the anæsthetizer's attention. The least change observed in the complexion or depth and regularity of respiration demands prompt treatment. The same may be said for the condition of the pupil. If it dilates while the patient is inhaling the anæsthetic or during narcosis, means of resuscitation should at once be used.

Promptness in interfering is all important. This was one trouble with the first case narrated by Dr. Packard. After the radial pulse became weak, the operation of perineal section was continued and efforts to resuscitate postponed because some one imagined the pulse in the *posterior tibial artery* was good.¹

The reporter of this case also criticises the *suffocating manner* in which a large amount of chloroform was given by a "raw-dresser," and the fact that the man was treated for suffocation by tracheotomy instead of for heart failure. Had he been treated for the latter trouble, he believes "the chances for recovery might have been increased."

Next to *promptness* on the *slightest evidence* of trouble is *position*. The patient should be turned head down. I mention this specially because in some of the reported deaths it was evidently omitted. The head should be kept down during artificial respiration if this latter is necessary. In the chloroform cases at the Eye Hospital during the past six years, I have seen many patients with pallor and bad respiration revive as soon as their heads were lowered. In only two was artificial respiration necessary. One was a boy of 12 and the other a feeble old man of 84, with mitral regurgitation. Prof. Chisolm, whose large experience is known, tells me he has never seen a

patient fail to respond if inverted on the first appearance of *pallor* and has never had to resort to artificial respiration. As to hypodermic injections of stimulants, they are, it seems to me, only useful if the circulation is good. But with a fair circulation the above means are generally sufficient. With a very feeble, or no circulation, I doubt if the injections are even absorbed. In some reported cases from collapse from *ether*, I notice that more ether has been injected—probably on the ground of its primary effect being that of a cardiac stimulant. This seems to me to be wrong. Alcohol also is a stimulant; yet no one would inject more whiskey to revive a man who was dead-drunk. The case seems to me to be the same with ether. If it is absorbed at all, it can only add to the collapse. Atropia or ammonia would be the proper remedies, if any would be useful.

In the foregoing I know I have given no facts that are either new or original. From time to time the subject of anæsthesia comes up for discussion among all surgeons. The papers from which I have largely drawn in the preparation of this put this discussion on a new basis. It is now not: "Is one anæsthetic safer than another;" but "what are the clinical indications which are to be our guides in making the selection!" This method of discussing the subject is comparatively new.

Discussion.

DR. G. J. PRESTON said he felt very much interested in the paper of Dr. Woods. He remembered a discussion in this Society a few years ago, when chloroform was decided to be the better agent. The physiological action of the two drugs is an important factor. With chloroform the effects are sudden. With ether we can see the danger coming. The fact that oculists have been so successful with chloroform is due to the stimulating effects which chloroform first produces and that the operations are short. He thinks that the cases should be selected for the anæsthetic. Where there is bronchitis and other affections of the air-passages chloroform should be given. For prolonged operations without these complications, ether is best.

DR. J. G. WILTSHIRE said he was very much pleased to hear the paper. Chloroform depresses the heart, and stimulants are indicated. If chloroform inhibits the action of the pneumogastric nerve, does not atropia stimulate the excito-motors?

¹ *Medical Times and Gazette*, Oct. 15, 1853.

DR. ROBERT JOHNSON said such discussions should come up every year, because administrators of anæsthetics become so taken up with the one that they use, that they become careless as regards their danger. He called attention to two cases. One was a case of hare-lip. He gave chloroform, and the child died on the fourth day with capillary bronchitis. The other case was a man with Bright's disease, to whom he gave ether, and he made a good recovery. Atropia stimulates the respiratory centers; amyl nitrate is also a good stimulant.

DR. J. T. SMITH said the subject under discussion is an old one, but it is constantly recurring. The tide fluctuates in both directions; when men of great experience give such diverse opinions, both agents must be good. Ether is now more used than formerly, so more deaths have been reported. The safety of anæsthetics in ophthalmic practice is due to the fact that the operator is at the face of the patient and can observe more clearly any changes that might take place. He was glad that the subject was brought forward for discussion.

DR. W. B. PLATT said ether had won its way into England, where at one time prejudice was greatly against it. Chloroform is used more in Germany. Morphia was advocated by Prof. Tieste, of Leipsic. It was thought by its use less anæsthesia would be required. There will always be some cranks against the use of one or the other of the anæsthetics, just as similar individuals oppose vaccination, for example. He thinks that we will soon settle down to the use of ether again.

DR. G. H. ROHE said that he had had a good deal of experience with ether, and never had failed to anæsthetize his patient. He had one patient who died on the third day after operation for vesico-vaginal fistula, from pneumonia. What the cause of the pneumonia was he could not say. He now always has patients well protected by covering during ether administration. He never believed in Dr. Emmet's statement about the danger of ether in Bright's disease. He believes it is not good to give it in bronchitis. Ether increases the bronchial secretions, and the accumulations may be so great in the lungs as not to be thrown off. He believes that Dr. Sayre's method of giving saturated chloroform vapor is a dangerous one. Death usually takes place upon the addition of more chloroform. Both ether and chloroform depress the heart, as sphygmographic tracings have shown. He has not given alcohol for ten years, but uses

morphia and atropia before the anæsthetic. It reduces the reflex irritability of the larynx to the ether vapor.

DR. W. P. CHUNN said he had given both anæsthetics and never saw a life lost. Five or six years ago chloroform was in more common use than ether. Chloroform is more powerful in its effects and likewise more rapid, consequently more dangerous. Even if the chloroform is stopped before the muscles are relaxed anæsthesia will increase for a time. Chloroform in certain cases is fairly safe. A great deal depends on how it is given. In regard to ether he had never seen an accident.

DR. W. H. NORRIS thought that a great deal of the trouble which comes on from anæsthetics is due to the quality of the drug. He had given chloroform many times and he had only seen one case where it acted badly. Chloroform was used during the late war by all army surgeons and they agreed that it was the best anæsthetic. He had had little experience with the use of ether. He related a case of puerperal convulsions where he gave four ounces without effect. He asked the opinion of the members as to the use of the combination of chloroform and ether.

DR. W. WINSEY said, as to which is the safer of the two drugs, that those who use them will be guarded by the effects of either. He prefers ether. A patient under the influence of an anæsthetic is never free from danger, the administration of which should be entrusted to competent hands.

DR. C. W. MITCHELL said he had given both agents for the past seven years—though chloroform has been in more general use. He began its use at the Presbyterian Eye and Ear Hospital. He finds now that ether is more generally given than chloroform. Anæsthetics should be given as other drugs are; ether is not comparatively safe nor comparatively dangerous. Care should be practiced in the selection of cases. He had seen two deaths from the effects of each drug. The fact of concentration should be considered in ether as well as in chloroform. The bronchial secretions increased by the influence of ether, should be allowed to escape by turning the head to one side and pulling the lips apart by placing the fingers in the patient's mouth. The snoring of ether is the result of the accumulation of mucus in the pharynx. Of the two deaths from chloroform, in the first case the drug was given by an inhaling apparatus and only $\frac{2}{3}$ of one teaspoonful was used; in the second case a towel was used for the administration and the chloroform was only poured on once;

both patients died suddenly. In the first case of death from ether the patient died on the ninth day from pneumonia. He thinks that chloroform would have been better. The second case was a patient with cavities in both lungs, upon whom laparotomy was performed. The fifth day afterwards acute pulmonary trouble came on, producing severe pulmonary hemorrhage and finally death. Kidney trouble renders both drugs dangerous.

DR. L. E. NEALE was glad to observe the practical turn which Dr. Mitchell had given to the discussion in trying to select special anæsthetics for special cases and special conditions. Just here he thought it interesting and important to note that chloroform had thus far held the lead as an anæsthetic during parturition, and out of many hundred thousands times it has been given not a single well authenticated case of death is on record. This was possibly explained by the physiological hypertrophy of the heart preventing cerebral anæmia.

DR. L. McLANE TIFFANY said the question is not between chloroform and ether, but when we have to produce anæsthesia, how can we best bring it about? It is wrong to think we have only two drugs to select from. The recognition of the disease, the choice of the remedy and its application are the essential points to be considered. There is no such thing as a best anæsthetic. Then it comes to the indications; contra-indications to the use of ether rest largely in the lungs. It has occurred to him to change the anæsthetic even while operating. Chloroform is better in such conditions. He related a case where he removed a tumor from a patient's neck. He began anæsthesia with ether, the secretions from the bronchial tubes began to pour out so fast that the ether was discontinued and chloroform used instead. The patient did well after the change. In the aged, say 70 years, he always gives chloroform, and also in the young. In all other cases, other things being equal, he gives ether. He then related a case where the patient had both bronchitis and heart trouble. He gave chloroform and the patient did well. He always precedes the anæsthetic with morphia and atropia.

DR. J. E. MICHAEL said it is fortunate that this subject does recur for discussion. The tide is very apt to turn with experience. He is not given to ether alone nor to chloroform, for experience shows that both are dangerous and must be carefully watched. In both cases of death from chloroform reported by Dr. Mitchell there was found disease of the kidneys. If other things are equal in a pa-

tient with kidney disease he does not know which he would choose of the two anæsthetics; where there is much bronchial secretions ether is contra-indicated. Chloroform is best in tracheotomy. Select the anæsthetic according to the indications. The death from ether in the case related by Dr. Mitchell was caused by hemorrhage which it excited. These discussions will compel us to look at the matter from a clinical standpoint. The tendency seems decidedly towards reviewing the ground and to determine which is the better agent to use under certain circumstances.

DR. R. WINSLOW said that he was struck while abroad by the faulty methods employed in Billroth's clinic in administering the A. C. E. Mixture. It was frequently given in the upright position. One patient died from such methods of administration.

DR. HIRAM WOODS, in conclusion, said: What has been said by the gentlemen who have spoken recalled a remark he heard Dr. Tiffany make in this Society about four years ago, when this same subject was under discussion. He said: "No matter what anæsthetic you give you put the patient in a position greatly resembling death, and it always needs care to avoid stepping over the line." The main stay in the use of any anæsthetic is the recognition of danger. Drs. Preston and Smith have alluded to the pallor of the face as being more apt to be noticed when the operation is about that part of the body, and this, to an extent, explains why the oculist does not have many accidents. Another reason is that it is impossible for the operator to be at work on the eye while the anæsthetic is being given. Dr. Chisolm was the first he heard give this reason. When the operation begins, giving of the anæsthetic stops. If the patient awakens the anæsthetic has to be renewed, the operator stops, and as he wants to get back to his work as soon as possible, there is not much danger of the patient getting an overdose. Dr. Smith has also alluded to operations about the peritoneum as being specially dangerous. In the remarks made by Dr. Weir at the New York Academy, deaths during operations on the peritoneum are excluded by the speaker from deaths due to anæsthetics, because, I suppose, any injury to the peritoneum is so apt to be followed by shock. He thought Dr. Wiltshire must have misunderstood him, or he must have used the wrong word. Vulpian's experiments showed that anæsthetics increase, not decrease the inhibition of the vagus, hence atropia antagonized them. As the doctor says, part of the good effect of atropia

undoubtedly comes from the direct stimulation of the cardiac ganglia. Dr. Johnson's case of capillary bronchitis following the use of chloroform in an operation for hare-lip and cleft-palate is open to the objection that the operation involved the respiratory tract. Dr. Gerster thinks that all such operations should be excluded when we are speaking of the effects of anæsthetic agents on the lungs. The reason for the occurrence of lung troubles after operations was thought by Dr. Weir to be due to free use of antiseptics in surgical practice and to the prolonged exposure of the patient. Dr. Platt says the use of morphia is not as common abroad as it formerly was. It has been found that large doses depress the heart and add to the danger. This is just what one would expect from large doses. The larger the dose the more transient is the stage of stimulation and more profound the stage of depression. The dose should be small, not over $\frac{1}{8}$ gr. to $\frac{1}{4}$ gr. at most. Drs. Mitchell and Rohé each report fatal cases of pneumonia after the use of ether. Dr. Mitchell says the pneumonia is always catarrhal. One of the cases reported by Dr. Gerster was lobar pneumonia in the stage of engorgement. Neither of these gentlemen think ether is contraindicated in nephritis. He knows nothing of ether experimentally, but a reference to Dr. Gerster's paper in the *Medical Record* will show that many cases have occurred which show that ether is very dangerous in Bright's disease. He could not see how Dr. Rohé can find, in Dr. Sayre's remarks, teaching which advises the administration of a saturated chloroform atmosphere. Dr. Sayre gives a summary of the principles he advanced in 1876, which are substantially the same as those which he holds now. He is not acquainted with the article which Dr. Rohé says was published by Dr. Sayre some years ago in which he recommends the administration of a saturated vapor. His present paper and the extract he gives from his teachings in 1876 are directly against such practice. He agreed with Drs. Rohé and Chunn that many of the chloroform accidents occur just after more chloroform is poured on the towel. He believes this is so, because the anæsthetizer often puts the towel with the fresh chloroform just where he had it before. Dr. Sayre's method of using an inhaler prevents this accident from occurring. As regards Dr. Pancoast's case he did not wish to acquit chloroform of its share of the work. All that he claimed was that it is clearly shown that Dr. Pancoast gives chloroform for slight operations in a manner which many recognized authorities

consider wrong. If the interview from the daily papers which he quoted is correct, the man died apparently from shock due to the performance of a slight but painful operation during partial anæsthesia. There was of course more danger under the chloroform than there would have been without any anæsthetic. There was also more danger than there would have been had the chloroform been pushed to full narcosis.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, June 22, 1887.

H. AUGUSTUS WILSON, M.D., in the chair.

DR. B. F. BAER, read a paper on

Cystic Enlargement of the Vulvo-Vaginal Gland.

This case is specially interesting because of the size of the tumor, and of a mistaken diagnosis which had been made.

The patient, thirty-six years of age, married, but sterile, presented herself at the Polyclinic, and stated that she had "a rupture which would not go back," although she had been kept upon her back as long as two days at a time, and had been bandaged and compressed until she could no longer endure the suffering. Truss after truss had also been adjusted, but all to no purpose. On inquiry, it was learned that about one year before coming under observation, she noticed a small lump near the posterior commissure of the vulva, corresponding with the location of the vulvo-vaginal gland. It was painless, and gradually increased from below upward. At the time she presented herself it was as large as a duck's egg. During the first nine months' of its presence it produced no symptoms, except slight inconvenience from the swelling, but about three months before coming under my notice the tumor began to occasion difficulty on account of its size, and the friction produced in walking, and from a most interesting symptom, namely, obstruction to the flow of urine. During the act of micturition the urine would flow regularly for a short time, and then it would suddenly cease, to be followed by great pain. By an effort she could again start the flow, and then it would again abruptly stop. During the last few months, the tumor had so increased in size as to approach the symphysis pubis.

On examination, I found an elastic tumor making compression upon the urethra, and the mechanical interference was at once ex-

plained. When the bladder became full, the effort to empty the organ overcame the obstruction from pressure of the mass for a time, but as soon as the straining ceased the urethra would be again suddenly closed by the tumor. It required considerable force to displace the tumor so as to see the urethra. The tumor was not tender on pressure, and there were no signs of inflammatory action about it. There was marked fluctuation, and its size was not affected when the patient was in the recumbent position. The inguinal canal was empty, and there was nothing in the shape or character of the tumor which would indicate that it contained intestine. The diagnosis lay between hernia and hydrocele of the labium majorum, both of which are exceedingly rare, and abscess or cystic enlargement of the vulvo-vaginal gland, although the tumor was much larger than any I had ever seen from the latter cause. I advised its removal by extirpation, because my previous experience in the treatment of this disease has taught me that radical measures are necessary. The patient entered the hospital, and in the presence of the Polyclinic class I proceeded to operate. An incision was made at the lower and inner surface of the tumor, my intention being to try to enucleate it entire. But the cyst was ruptured by the effort, and a yellowish fluid escaped of the consistency of thick cream, but without odor. I next passed my finger within the collapsed sac, and found that it occupied a very extended surface—from the upper portion of the labium down to the ischio-rectal space. The secreting surface or membrane was very thick. It was not likely, therefore, that anything short of removal of the gland would effect a permanent cure.

This has been my experience with these cases, as I have said. But hemorrhage is sometimes great, and this has caused most authors to advise simply evacuation of the fluid, and injection or packing with iodine, or some other agent, to destroy the surface. It will be remembered that the gland is in close relation with the transverse perineal artery below, and with the bulb of the vestibule at its upper extremity. When, however, the organ is diseased and hypertrophied, the blood-vessels become greatly enlarged, as during pregnancy, making this locality much more vascular. Then the gland, as the result of its increased size, extends much further up, and becomes surrounded by the network of veins called the bulb of the vestibule, and there is closer contact with the vessels at the lower surface of the gland.

In pursuance of my original plan, I en-

deavored to separate the sac from its close attachments with the handle of the scalpel; but this I was unable to do, and I was compelled to dissect it out with the edge of the knife. The extent of surface was much greater than I had anticipated, even, and the hemorrhage very considerable; that from the arteries was controlled by ligation, but I found great difficulty in checking the venous. Hot water and compression failed, and I was finally compelled to pack the cavity with pledgets of cotton saturated with Monsell's solution, and supplement this with pressure applied by vaginal tampon and with a compress held in position by means of a "T" bandage. The dressing was permitted to remain in position twenty-four hours (there being no untoward symptoms), when the bandage and compress were removed. I now ordered the constant application of lead-water and laudanum, which gave great comfort, as the parts were hot and somewhat swollen. Very little pain was complained of, however.

The next day a part of the packing was removed, and a little more each day after—as much as came away easily. Irrigation with carbolyzed water every four hours, and the constant application of the lead-water and laudanum, constituted the after-treatment. At the end of a week the last pledget of packing came away, and in another week the patient left the hospital, the wound having almost entirely healed. I was much gratified with the rapid recovery, for I feared that there might be extensive sloughing and granulation.

The operation occurred some months ago. The patient is entirely cured.

In simple retention cysts I have succeeded in curing the case by incision and packing. In abscess of this gland, treatment of that kind will usually be sufficient. One word in regard to the cause of these cysts. In the present case I do not know the cause. A common cause is injury from coition or from childbirth, the former most commonly. It sometimes occurs as a result of the first coition. There is no doubt that some of the cases have a gonorrhœal origin, but I do not believe that this cause is as common as is often stated.

Discussion.

DR. J. C. DA COSTA said: I remember distinctly two or three cases seen within a few months. In one case a large quantity of fluid was removed. Another case was of chronic inflammation in the left labium. I opened it, and treated it in the ordinary way, but it rapidly returned. I then thought of dissecting it out, but fearing just what Dr.

Baer met with, tried another method of treatment, which has succeeded well in some cases. After emptying the cyst, I took a curette and scraped the inside; then, with a swab, applied a strong preparation of iodine, consisting of pure iodine with iodide of potassium dissolved in glycerine. I next took two or three deep sutures, bringing the walls in close contact, and in that way succeeded in obliterating the whole sac.

DR. J. B. DEEVER said: With regard to the causation of these tumors of the vulvo-vaginal gland, my experience is not in accord with that of Dr. Baer. I have not found injury a common cause. The majority of cases which I have seen have apparently arisen without any special cause. I cannot understand the difficulty experienced in the arrest of hemorrhage. I should simply pack the sac, and stitch the edges of the wound over it.

DR. W. S. STEWART said: I have had some experience in operating on these cases. I do not use a general anæsthetic, but prefer to employ cocaine solution. I find that cocaine, in from a five to ten per cent. solution, has an astringent effect. In a case in which I employed this in the removal of

one of these glands, I had expected hemorrhage, for the arteries in this location are numerous, and the veins valveless. During the removal of the gland I had no difficulty in controlling the bleeding by applications of the solution. After the operation the use of sutures brought the surfaces accurately together, and there was no subsequent hemorrhage. In order to keep down inflammatory trouble, I made applications of phenol sodique.

DR. BAER said: The arrest of hemorrhage would not seem to be a difficult matter where the gland is of normal size, but when the organ increases to a large size the vessels become much larger. If Dr. Deaver had seen the efforts which I made to check the hemorrhage by pressure, I think that he would have agreed with me that it was difficult to control. I had feared that I might have a granulating surface and some sloughing. The wound, however, healed nicely, and I have not had a better result under the best antiseptic precautions. Cocaine would not have arrested the bleeding, for the hemorrhage did not come from the incision, but from the vessels beneath the tumor.

EDITORIAL DEPARTMENT.

PERISCOPE.

Operation for Intra-Cranial Hemorrhage.

On June 21 Professor Thornley Stoker, of London, operated on a man about 50 years old, who had sustained an injury to his head on June 12. His symptoms pointed to a fracture of the skull with intra-cranial hemorrhage engaging the motor area of the right hemisphere. He had left hemiplegia, was comatose, and had such interference with the functions of respiration and deglutition as pointed to the existence of pressure at the base of the brain. He was getting worse, and sinking rapidly. Two large trephine openings were made over the parts of the motor area indicated by the paralysis, and a clot, due to rupture of the middle meningeal artery, was removed without much difficulty. It was an inch thick, and over four inches in diameter. The patient recovered consciousness and partial use of his arm and leg while on the operating table. In three days he had fully recovered all his faculties and has since progressed uninterruptedly towards health. The case was treated all through with antiseptic measures.

Examination of Urine by Country Practitioners.

Dr. James Ware, of Marksville, La., in a paper read before the Louisiana State Medical Society, and published in the *New Orleans Medical and Surgical Journal*, July, 1887, says:

"Within the last few years I have been very much impressed with the necessity of examining the urine as a means of diagnosis. It is to be supposed that city physicians, whose opportunities for study and improvement are so great, never leave this important matter undone; but in the country I believe the urine is examined systematically by very few physicians. Even in cases of disease of the urethra, bladder, or kidneys, it is not always done; and frequently, when the necessity of it is felt, the urine is bottled and sent to some town or city where the necessary knowledge and instruments may be found. The risk of changes occurring in the fluid by time, temperature, etc., always ought to prevent the adoption of this method.

"The lack of practical skill on the part of country practitioners in important surgical

cases, and in cases of gynecology, and in those instances of profound disease requiring a high order of mind and long experience to diagnose correctly, I say the lack of skill here on our part is certainly to a great extent excusable. What we want to know is how unerringly to tell the common diseases of the country, and then successfully to treat them.

"It would undoubtedly be better for us and our patients to know how to treat properly, and bring to a favorable issue, the varied forms of malarial disease, the ordinary maladies of inflammation, the common diseases of women and children, than to be able skillfully to perform ovariectomy or lithotomy. Many country physicians treat these diseases remarkably well. As a class we are acute, industrious, and observing, and receive less for what we do than any other body of intelligent men in the world."

He urges and illustrates the importance of knowing how to examine the urine, and of doing it:

"In my opinion the time is rapidly approaching when physicians will consider it their duty every year carefully to examine the urine of every member of all the families under their medical charge. Conscientiousness on our part and increasing knowledge on the part of the people will demand it. It must be done for the same reason that we vaccinate—to protect against the inroads of fatal disease. The value of an early discovery of many diseases is indisputable. I ask you to look at tables prepared by medical examiners for life insurance companies, and note the large percentage of cases of incipient Bright's disease and diabetes discovered by this necessary examination.

"My principal object in writing these few pages is to call attention to the number of times that the urine is left unnoticed in cases where it should be closely examined. This paper is designed, not for those who know more of this subject than I do, but for those who know less. 'I came to call, not the righteous to repentance, but sinners.' Dr. Graves said that he wanted as his epitaph: Dr. Graves—he fed fevers. I want mine to read: Dr. Ware—he examined the urine."

Insanity and Oophorectomy.

Dr. William M. Leszynsky, in a paper in the *New York Medical Journal*, June 25th, 1887, says:

In only a small percentage of the insane can we discover a somatic basis for the mental derangement, although a multitude of abnormal physical conditions have been

credited with a causative influence in the production of insanity.

Insanity at times occurs in persons who are the subjects of phthisis, chronic nephritis, alcoholism, syphilis, and numerous other morbid conditions.

That the existence of any of these diseases does not render such individuals exempt from the development of mental symptoms is unnecessary to mention. If they do not act as an exciting cause, they are usually contributory elements in aggravating or increasing the gravity of the situation.

As is well known, the psychical causes are generally the predominating factors in the production of insanity, the constitutional predisposition and an unstable nervous organization being the fertile soil for its development.

The fact that the exciting cause of an attack of insanity can occasionally be justly attributed to reflex irritation arising from uterine or ovarian disease, cannot be questioned.

The premature and indiscriminate removal of the ovaries in cases of insanity and other neuroses has of late become so frequent and flagrant a procedure as to demand an emphatic protest against such reprehensible measures and such illegitimate practice.

He then gives the history of two cases in which the ovaries were removed for insanity, death following in one case, and the other patient continuing to be as insane as ever.

He adds: These two cases that have been under my immediate supervision amply demonstrate the fact that the removal of the ovaries was an illegitimate and unjustifiable operation, and wholly unwarranted under the circumstances.

Practical utility and conservative principles should never be sacrificed on the altar of presumable brilliancy and self-glorification. The jeopardizing of human life and the nullification of physiological functions should never be instituted through irrational enthusiasm.

Physicians who are dominated by their specialistic proclivities, thereby being frequently misled into irrationality in their procedures and methods, are, fortunately, not a preponderating element in the ranks of the medical profession.

If in any case of insanity the existence of a pathological condition of the uterus or its appendages can be unequivocally demonstrated, and such morbid state be by logical process and clinical evidence indubitably proved to be either the exciting cause or a preponderating contributory influence in the

production of the mental derangement, then, *and only under such circumstances*, after all other methods of treatment have been exhausted, can surgical interference such as oophorectomy be considered a legitimate procedure.

A Sexless Being.

In the *Gazette Médicale de Paris*, Dr. Polaillon describes a remarkable case of malformation in a patient aged 31, who died of hepatic abscess in the Hôpital de la Pitié. The patient had been a tailor, then a general dealer. He presented the external appearances of a woman, being completely beardless, and bearing small but distinct mammae. His voice was feminine, his stature low, and he was a great coward, displaying much mental perturbation at the prospect of dressing his abscess, and shrieking during the process. The pelvis was broad, and quite of the female type. From a distinct and prominent mons veneris ran two cutaneous folds, corresponding precisely to labia majora; they joined posteriorly in front of the anus. The penis was hardly an inch and a half long, but perfectly formed, and the relations of the corpora cavernosa, glans, and urethra were normal. The prepuce was long, and formed a phimosi. The scrotum was small and perfectly empty, and there was no depression or cavity representing a vaginal or vulvar orifice. The most remarkable feature of the case was the entire absence of testes, spermatic cord, and vesiculæ seminales. The neck of the bladder was of the male type; no trace of ovaries or uterus existed. The rectovesical pouch was very deep.

Boracic Acid for Leucorrhœa.

From the excellent results which are yielded by boracic acid packing in chronic suppurating otitis, Dr. N. F. Schwartz (*St. Louis Courier of Medicine*, June, 1887) was led to employ it in a case of leucorrhœa which had resisted the most persevering use of the ordinary remedies. The experiment was successful within a fortnight, and the patient has remained well for several months since. Dr. Schwartz states that he has been equally successful in a number of other cases. His manner of using it is as follows: Having first irritated the vagina with water at as high a temperature as can well be borne by patient, a cylindrical speculum is introduced, and the vaginal walls very carefully dried, first with a soft sponge and then with absorbent cotton. This done, boracic acid in crystals is poured into the mouth of the speculum, and pushed up against the uterus and vault of the vagina

with a clean cork caught in a uterine sponge-carrier, sufficient acid being used to surround and bury the intravaginal portion of cervix, filling the upper part of vagina. A tampon of absorbent cotton is then firmly pressed against the packing, and held *in situ* until the folds of the vaginal walls close over it as the speculum is withdrawn.

This should be allowed to remain three or four days, or even longer, as after this time there still remain some undissolved particles of the acid, nor will the tampon seem at all offensive. The ostium vaginae, if examined in twenty-four hours, instead of being besmeared with the leucorrhœal secretion or discharge, presents a clean appearance, and bathed in a watery fluid, which begins to appear several hours after the packing has been placed, and in his cases this was the only discharge noticed afterwards.

However, a second or even a third repetition may be necessary, but in none of his cases, numbering nearly a score, has he found more than a second packing called for, and in many one sufficed; and in no instance has its use occasioned pain, not even inconvenience.

Apomorphine and Morphine in Whooping-cough.

Dr. P. F. Fedoroff states that he has obtained good results in whooping-cough by the internal use of the following mixture:

℞ Morphine, muriat. gr. ij
Apomorphine, muriat. gr. j
Acid. muriatic. ʒ ss
Aq. destil. ʒ vāj

M. D. S., a teaspoonful four times a day.

The paroxysms are lessened both in number and frequency after the few first doses of the mixture.

New Views on Prurigo.

Dr. Tom Robinson, in the *Jour. of Cutaneous and Venereal Diseases* for July, 1887, sums up his observations in the following postulates:

I.—There is not such a disease as *prurigo*.

II.—That all cases of itching skins have a recognized and discoverable cause.

III.—That all the group of symptoms which are known as prurigo are the result of scratching, and are simply symptoms.

IV.—All scratched skins which have advanced to an elephantoid state, and which have set up enlargement of lymphatic glands, are beyond the reach of remedies or hope.

V.—That the pruriginous skin of children has its origin in developing hair follicles, which progresses from birth to puberty, when it stops.

VI.—That excessive itching does not occur in those situations where the hair grows luxuriantly.

VII.—That what is known as winter prurigo is due to imprisoned hairs.

VIII.—That an irritable state of the skin is always associated with an irritable state of the mucous and synovial membranes.

Localised Facial Sweating.

Dr. N. A. Parfianovitch, of Kaluga, relates two instances of this rare affection, one occurring in his own person. About six years ago he went through an attack of typhus fever, complicated with suppuration of the right parotid gland; this left behind it a considerable impairment of sensibility in the masseter muscles and the skin of the right cheek, with marked liability to localised sweating. The perspiration, which is so profuse that large drops run down the cheek, is limited to the right temporal region, and invariably occurs during mastication. Another case is that of a lady, who also had a right parotid abscess, with subsequent formation of a deep scar, and who sometimes suffers from sweating limited to her cheeks, and coming on only on mastication.—*British Med. Journal*.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT LITERATURE.

—Ticknor & Co., Boston, announce "Home Sanitation," a manual for housekeepers, by the Sanitary Science Club of the Association of Collegiate Alumnae, edited by Ellen H. Richards and Marion Talbot. The object of this manual is to arouse the interest of housekeepers in the sanitary conditions of their homes, and to indicate the points requiring investigation, the methods of examination, and the practical remedies.

BOOK NOTICES.

[Those sending Books for Review will oblige our readers by always stating publication price. In the case of Reprints, authors are requested to state the conditions upon which copies may be obtained by those of our readers interested in the subjects treated.]

Transactions of the American Gynecological Society, Volume II, for the Year 1886. 8vo, pp. 516.

It is impossible, in the space which we can spare, to do more than notice this volume of transactions, which contains a large number of elaborate papers by the most eminent gynecologists in America, and a very hand-

some phototype of the late Dr. Albert H. Smith, of Philadelphia. As unusually interesting, we might mention a paper on *The Influence of Maternal Impressions*, by Dr. Fordyce Barker, which, with the discussion, occupies forty-five pages of the volume. The general conclusion was in favor of the belief—which has often been scouted as absurd—that strong maternal impressions may induce physical changes in the fetus *in utero*.

For other very interesting matter, we refer our readers to the book itself.

A System of Gynecology. By American authors. Edited by Matthew D. Mann, A.M., M.D., Professor of Obstetrics and Gynecology in the Medical Department of the University of Buffalo, N. Y. Vol. I, Illustrated. Royal Octavo, pp. 789. Philadelphia: Lea Brothers & Co., 1887.

This magnificent volume not only contains a summary of the present knowledge in regard to the various subjects of which it treats, but it is also a splendid monument to the achievements of American practitioners in this department of work. There is probably no field of medical practice in which American skill and ingenuity have attained such signal results as in that of Gynecology, and the volume before us, with those which are to follow may be regarded as especially an American work for American readers. At the same time it will doubtless become indispensable to gynecologists all over the world.

The Curability of insanity and the individual treatment of the insane.

By John S. Butler, M. D., late Physician and Superintendent of the Connecticut Retreat for the Insane, etc. 6¾x5 inches. Pp. 59. New York and London: G. P. Putnam's Sons, 1887.

This admirable little book contains the earnest plea of an experienced man for careful and kindly individual treatment of the insane. The whole scheme of the book is founded upon the idea that insanity is a disease of the brain. "Whoever," the author quotes from Sir James McIntosh's *Life of Robert Hall*, "has brought himself to consider a disease of the brain as differing only in a degree from a disease of the lung, has robbed insanity of that mysterious horror which forms its chief malignity." With this as a guiding thought, Dr. Butler has written a book so full of wise council and humane purpose that we can with assurance recommend it heartily to all who have dealings with the insane.

THE Medical and Surgical Reporter.

**A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.**

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets,
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The edition for this week is 5,000 copies.

THE TREATMENT OF VARICOSE VEINS OF THE LEG.

Ordinarily, persons afflicted with varicose veins of the leg expect nothing more than some amelioration of their condition, or some means of getting along with it. The trouble is regarded as incurable, just as a hernia would be. For a hernia a truss is worn, and for varicose veins an elastic stocking is generally used. In many cases nothing whatever is done for varicosities of the leg, and the sufferer has to bear the distress, and run the risks of his condition as best he can.

If the veins are not very much enlarged, this may not be an unwise plan. But in a case in which the varicosity is very pronounced the risks are too great to warrant letting the veins alone. The risk of ulceration, of rupture and hemorrhage, of phlebitis, of extension of the varicose condition, is so great that something ought to be done.

This something should consist in the adoption of proper medicinal, mechanical or surgical treatment. Under the head of medicinal treatment may be classed the use of general tonics, the relief of constipation, and the employment of drugs which act upon the walls of the veins. Of these, none now enjoys a better reputation than hamamelis, strongly recommended to the profes-

sion for this purpose by Dr. J. H. Musser a few years ago. It can be given in teaspoonful doses of the fluid extract three or four times a day.

Mechanical treatment consists in the use of a well-fitting elastic stocking, which should extend from the heel to a point well above the highest dilatation, or of a carefully applied bandage. Martin's rubber bandage serves a good purpose, if well put on and if kept clean. It usually produces free sweating, but the discomforts of sweating can be much lessened by putting the bandage on over a clean white cotton stocking.

Surgical treatment of varicose veins consists in injecting them with some coagulating substance, in ligating them, or in excising a portion of them.

If injection be selected, it is best performed as follows: The circulation is controlled with an Esmarch's rubber tube, applied round the leg above the point where the injection is to be inserted, while the patient is standing up. At first only a few turns should be put on, in order to fill the veins up, and then the tube should be wrapped tight enough to cut off all the circulation. Then a single drop of pure carbolic acid should be injected into the veins at several points about an inch apart, and the site of each puncture should be touched with collodion and covered with a little cotton and collodion.

The Esmarch's tube should be left in position for fifteen minutes, and then be gradually removed, so as to avoid the risk of having an embolus swept into the heart. After the operation, the patient should keep his bed for at least a week.

The operation of ligation of varicose veins of the leg is best performed by distending them fully, and then slipping a strong cat-gut thread carefully under them and over them—passing in and out at the same openings on each side—just as is done in ligating varicose veins in the scrotum.

The operation of excision is the most radical and the most curative of all. To perform this operation it is necessary to distend the veins with a bandage, to make a clean cut down upon them, and to pass a strong cat-gut ligature around the lowest point. The vein must then be seized above the ligature with a strong pair of forceps, and lifted up and cut off below the forceps. It is then stripped up, each radicle met with being ligated and divided, until several inches are clear, when the main vein is to be ligated at the highest accessible point, and cut off below the ligature. The wound

should be treated aseptically, closed up, and covered with an aseptic dressing.

Several veins may be operated upon in this way at one time, and even both legs may be operated upon at once. After the operation the patient's leg, or legs, should be bandaged, and he should be confined to bed for eight or ten days.

This operation we can recommend to our readers, if it be performed with care and with correct aseptic precautions. By this we do not mean Listerism, but the improved aseptic method of the present day.

SPECIALISTS' SLANG.

In every approach to scientific exactness there is an outcropping of new words to express the new ideas and finer distinctions which thus arise. The Greek conglomerates which learned neurologists employ to split hairs with are certainly distressing; but for general inscrutability we would commend the case records of the modern ophthalmologist. It is only justice to the members of this most valued and affluent guild to say that their specialty presents, perhaps, the nearest approach to an exact science of any branch of medicine. Nevertheless, the hieroglyphics in which they express the exactness of their observations are eminently depressing, and by nine readers out of ten they are looked upon with a curious resentment not unmingled with awe. We feel, therefore, greatly favored in that we could present, in this and in the preceding number of the *REPORTER*, two plain, common-sense, practical papers on the methods of treating common disorders of the eye, and we are sure that our readers will join us in thanking Drs. Turnbull and Jackson for their self-restraint in avoiding these objectionable words and symbols which they would have undoubtedly employed, with great propriety, in talking with each other.

GAS IN THE BLADDER.

M. Charles Tisné reports in the *Annales Médico-Chirurgicales*, of Paris, June, 1887, the case of a man, 77 years old, who had had high fever for several days, and at the time of M. Tisné's visit was profoundly prostrated. For a long time he had micturated only with great and prolonged effort, and drop by drop.

At this time his bladder was much distended, and M. Tisné drew off half of the ammoniacal and purulent urine with a catheter, and injected nearly a pint of boric acid solution. By the next day there was a considerable quantity of gas in the bladder

which escaped through the catheter when it was introduced. This happened five times in ten days, and ceased as the character of the urine improved.

Three months later an abscess broke over the region of the left kidney, and the amount of pus in the urine diminished very much, and no more gas was found in it.

The development of gas in the bladder has been attributed by Guiard to the change of sugar in the urine into alcohol and carbonic acid by fermentation. This explanation may apply to diabetic patients, but cannot apply to non-diabetic. And in a number of cases mentioned by Tisné gas from the bladder has been analyzed and found to be like atmospheric air.

In his own case, the gas may have been disengaged from an alkaline and ammoniacal urine by the action of boracic acid upon some of its ingredients.

In any similar case it would be interesting to make some experiments with the patient's urine and the antiseptic solution used to wash out the bladder, so as to note any chemical reaction between them. It would be interesting also to have an analysis of the gas made. But this would not be easy to accomplish, except in a hospital. If it were done, however, it would clear up a very obscure subject, and throw light on a very curious phenomenon.

A QUEER THEORY.

At the last meeting of the German Surgical Society, Prof. Albrecht said that after the progenitors of mankind had gone for millions of years on all-fours, the sudden resolution to use the anterior extremities only as organs of prehension and the posterior extremities only for locomotion, could not go unpunished. Bow-legs, knock-knees and hunch-backs are to be attributed to the fact that mankind adopted this unnatural posture. To this also is to be attributed the dislocation of many of the viscera. The descent of the testicle is an example of this, and the scrotum is nothing but a normal inguinal hernia.

All these dreadful things Albrecht charges to going on two feet instead of four. He sees no flaw in his argument; although others might suggest that there is as yet no evidence that man's progenitors ever went on four legs, or that it is more natural for the testicles to remain inside of the belly than to be outside of it. Nor does he seem to recall the fact that almost all four-footed beasts carry their testicles in a scrotum, and have the same general arrangement of viscera as man has.

On the whole, we would not recommend mankind to take to creeping again, with hope that they would cure their bow-legs or get their pelvic viscera into other positions, or that they would be any better off if they did.

If we were to offer a suggestion to Prof. Albrecht, it would be that in Vienna knock-knee is more likely to be prevented if the inhabitants among whom this deformity is found were better fed and better housed, than if they were to act upon his interesting, but groundless theory.

NOTES AND COMMENTS.

The Abuses of Milk Diet in Therapeutics.

Dr. Roberts Bartholow presents the following timely paper in the *Journal of Reconstruction* of July 12, 1887:

The therapeutical employment of milk, not only has been popularized and the lay public made familiar with its various adaptations, but in the wake of the general appreciation have followed the usual exaggerations, and hence it is prescribed with little regard to the conditions properly requiring it. Under these circumstances it seems desirable to indicate the limitations of this therapeutical food, and to show wherein it may be hurtful rather than beneficial.

In certain disorders of the digestive functions, milk causes a sense of discomfort, decided uneasiness, oppression—sometimes even pain, and it prolongs the morbid condition. The cases of this kind may be grouped into two classes: those in whom the casein is the offending material; those who cannot properly digest the cream or butter. We find examples of the first class more frequently amongst children, but they are by no means uncommon in adults. They are detected the more readily in early life, because the curds are rejected by vomiting, or appear undigested in the stools. Adults unable to digest casein, or who digest it slowly or painfully, have epigastric distress, heaviness and oppression for several hours after meals, stupor and disinclination for exertion coming on after an hour or two, and continuing until the offending material has passed well down the intestines.

An excellent substitute for the milk when the casein disagrees is barley-water with cream. The barley-water should be carefully strained and have the density of good skimmed milk, and one sixth or one-fourth cream added, so that the mixture has the consistency of rich milk.

The second class of subjects to whom milk is unadapted are the cases of duodenal, hepatic and pancreatic diseases, because of the deficiency in the secretions necessary to the process of emulsifying fats, and preparing them for entrance into the lymph vessels. Fats decomposing form very irritating fat acids, and the change in the reaction of the intestinal juices is the cause of various secondary troubles in the biliary functions and elsewhere. To fit milk for use under such circumstances, it must be skimmed, and about the time the stomach digestion is completed, aids to the intestinal digestion should be administered. Such aids are a soda alkali, and it may be, some pancreatic solution to effect complete digestion of the fatty constituents.

The mere bulk of the milk is an objection to its use in certain diseases. In dilatation of the stomach, the space occupied by the necessary quantity perpetuates the disease. The reflex effects of distension of the stomach in cases of weak heart, and in angina pectoris, may not only cause distressing symptoms, but may even prove fatal. It cannot be too strongly stated that milk is a highly objectionable aliment in heart diseases, whenever the motor apparatus of the organ is diseased, and whenever its movements are readily influenced by morbid states of the stomach through the reflex channels.

In no malady, as I conceive, is milk more abused than in acute rheumatism. It is very often the chief—sometimes the only aliment employed during the whole course of this disease. Besides the objection inherent in its mere bulk, certain theoretical considerations of its nature should have considerable weight in deciding the question of use. The very obvious objection that milk furnishes lactic acid as a product of its fermentation, should not be ignored. All the world knows the intimate relation between lactic acid and the rheumatic poison. By the introduction of lactic acid, a form of endocarditis not distinguishable from the rheumatic, is set up, and of those diabetics treated by lactic acid, a considerable proportion suffered from attacks of rheumatic fever (acute rheumatism). It is difficult, of course, to determine this point with certainty, but I have reason to believe that patients with rheumatic fever do not get well so quickly, and are much more apt to have relapses when they consume much milk during the course of the disease. Surely, sufficient reasons exist for undertaking a thorough investigation of the question. My

own practice, in the cases in which I am consulted, is to advise against the use of milk as an aliment in acute rheumatism.

In typhoid fever, milk is the one food now given, irrespective of the character of the cases. Of late, this almost universal practice has come to be challenged. It has been depended on, without investigating the state of the digestive functions, and quite unmindful of the effect it may have on heat production. It is often given in too great quantity at a time, or so frequently that the stomach has not disposed of one quota before another is thrust upon it. Unless the gastric juice has preserved to a considerable extent its power of converting the albuminoids into peptones—which we have no right to expect—the casein resists its action; hence it follows that the materials of digestion should be administered soon after the milk is taken, and to prescribe it without reference to the ability of the stomach to dispose of it is to insure increased fever and delirium, and more frequent stools. Beside supplying the means for proper digestion of the milk, attention should be given to its administration at such intervals that every portion given may be disposed of before another is permitted to enter the stomach. It is a trite observation, which is not therefore less true, that it is more important to the nutrition if some food be well digested rather than a large amount be merely swallowed.

Notwithstanding, since Donkin's first reports, milk has entered largely into the dietary of diabetics, its utility has recently come to be seriously questioned. If conversion of milk sugar into grape sugar does not take place, there can be no doubt of the value of milk in this disease, since it possesses so great a number of alimentary constituents. If, as is now asserted, this conversion does take place, the free administration of milk in diabetics, must be regarded as an abuse.

Mistletoe.

E. W. Lane, M. D., writes as follows in the *Atlanta Medical and Surgical Journal* of July, 1887: "What Dr. Todd says of mistletoe is true, so far as my experience goes, and it is a remedy much used in this section by the country doctors. We find it to be a sure and safe remedy. Its action seems to be directed more on the fundus of the uterus than to the whole organ. Ergot is not a safe remedy, as its action takes in the whole organ. Mistletoe is the remedy to expel a retained placenta—it has never failed us. Ergot is the remedy not to give in such

cases. Mistletoe was the subject of discussion at our last meeting of the Ogeechee Medical Association. It was brought out that Dr. T. E. Johnson had successfully treated a case of hydatids of the uterus, the remedy expelling the tumors in a few days. It is used also to expel a dead foetus."

The REPORTER would be glad to have the experience of such of its readers as are familiar with this drug.

Indigo as an Emmenagogue.

Dr. S. T. Yount, of La Fayette, Ind., in a paper read before the Tippecanoe County Medical Society, recommends very highly the employment of indigo as an emmenagogue. He writes: "It is perfectly safe, thoroughly reliable, and painless in its action. It is insoluble in water or alcohol, but readily dissolves in strong sulphuric acid. This so changes its character that it is then readily soluble in water without changing its color.

"It is odorless and tasteless, and may be given in doses of $\frac{3}{4}$ j to $\frac{3}{4}$ ss. The great difficulty is the nausea and vomiting which the crude drug produces when given in very large doses. There are three varieties of the crude drug: Bengal, Turkey, and Chinese.

"The Bengal is richest in coloring matter, containing about fifty per cent., and inasmuch as the virtue resides in the coloring matter, the best effects are obtained from this variety. As an emmenagogue it has been used in my practice about a year and a half. My attention was first directed to it on one occasion when I was called to remove a retained placenta in a case of abortion at the third month. Naturally inquiring what had been taken to produce the abortion, I was told that the lady had taken indigo in teaspoonful doses three times a day, that she had taken it several times, and always with a most satisfactory result to her.

"She informed me at the time that it always produced great nausea and watery discharges from the bowels. Acting on the suggestion offered by this case, I tried it in many and various cases. In one case, where a young lady, aged eighteen, had missed for thirteen months, the menses returned after she had taken the crude indigo for two weeks; but the disgust and nausea produced by the bulky powder rendered her unable to continue it longer, and she menstruated three more months and then stopped again. After using the remedy for eight or nine months in this crude state, I set about to find some way of condensing it, or rendering it less bulky, for it is the bulk of the dose,

not the remedy, that disturbs the stomach and disgusts the patient. About a month later Mr. O. G. Zerse, an apothecary of La Fayette, turned over to me a concentrated extract, as he called it, five grains of the extract equalling twenty-six grains of the crude drug. I have since then used it in forty-eight cases of amenorrhœa, of all kinds and causes, with but three failures, and a colleague has used it in six cases without any failure. To test its effect I have given the remedy in the amenorrhœa of phthisis, and have always had a definite result, namely, the appearance of the menses, the menses stopping again when the remedy was stopped. The effects with the crude drug and the concentrated preparation are identical, except that the nausea does not occur when the extract is used. Then the menses come on painlessly and very suddenly. There is no warning given. In thirty cases the effects occurred about two days after the last dose, the menses coming on without any warning, gushing out and running often to a flow. The hemorrhage in none of the cases was dangerous or alarming. During the administration of the drug the os uteri becomes soft and patulous, admitting the end of index-finger. There is often a serous discharge from the vagina. The urine becomes of a brownish-green color and offensive odor. The stools are of a bluish color. The passages are watery and offensive.

"To summarize, indigo is an emmenagogue of decided value in any case. It should not be given to pregnant women. It should not be given where there is an irritable stomach. It should not be given in cases in which there is a history of previous pelvic inflammation. It should not be given in cases where there is marked cerebral anæmia. It may be given in doses of $\mathfrak{z}\text{ j}$ to $\mathfrak{z}\text{ ss}$, two or three times a day, of the crude drug, or in five-grain doses of the concentrated extract. The powder of the crude drug should be given mixed with a little subnitrate of bismuth, and the patient should drink a little whiskey afterward. In cases in which it is given continuously for a long period, give tr. gentian comp. after each dose. Give the concentrated extract in capsules mixed with extract of gentian and subnitrate of bismuth."

—*Medical Record*.

—Sir William Gull treats his aristocratic patients, as he wishes the profession to believe, by leaving them to their warm bed and nature's efforts.

For Vomiting of Pregnancy.

Professor H. C. Grosvenor (homœopath) says: "My usual treatment is sulphate of hydrastia, dissolved in water, sufficient to give the water a straw color. To be taken *ad lib.* If heartburn accompanies the nausea, put salicylic acid in the same glass. For pyrosis use Apollinaris water. When nausea is very severe two grains of svapnia [a preparation of opium] in half a glass of water is to be taken in teaspoonful doses." Professor John W. Streeter [homœopath] spoke upon the same paper as follows: "I have had some unmanageable cases. My best remedy is chicken's gizzard [ingluvin], ten grains, as often as necessary. My second best remedy is skunk cabbage, 400x. Look out for some local cause. Examine the pelvic organs." It will be seen that the above professors recommend only one homœopathic remedy, viz., skunk cabbage.—*N. Y. Medical Record*, July 16, 1887.

CORRESPONDENCE.

Plugging the Nostrils.

EDS. MED. AND SURG. REPORTER:

Having lately read of a fatal case of epistaxis (something that should never occur when the nostril is properly plugged), I am prompted to give some of my experience. The lint plug, tied through the nostril with a string, is hard to remove; and I have known it, especially in typhoid fever, to excite so much nausea that it could not be retained.

The plan I have followed for many years is to take the cæcum of a chicken, turn it inside out, and scrape the mucous and muscular coats away, leaving the peritoneum. This makes a sack that when passed through the nostril and distended with water and tied in front makes a very efficient plug—large enough to evenly fill the nostril, preventing hemorrhage very effectually. It does not irritate nor stick fast, and is very easily removed by snipping off the outer end, allowing the water to escape, when the gut is very easily withdrawn. I do not claim this as original.

When a chicken is not handy, I have used a gum condom in the same way; and the smaller one of a set of Barnes' bags has answered the purpose very well in a large nostril.

I have tried to have gum bags made on purpose for checking hemorrhage from the nasal cavities, but have been unable to get it done as yet.

With the chicken gut or gum sack thoroughly distended with water and tied to prevent it escaping, I do not believe it possible for a patient to bleed dangerously from the nose.

A. ADY, M. D.

Muscatine, Ia.

Carbon Bisulphide.

EDS. MED. AND SURG. REPORTER :

In the last REPORTER I observe, in a communication from Wallace A. Briggs, M. D., that he commends the use of carbon bisulphide in solution with an aromatic water and milk. Am I right in assuming that this mixture is to be given by the rectum? And if so, is it not likely that so frequent a repetition as he advises would cause diarrhoea? Would it not be well to add some pancreatine to the milky solution?

D. E. MATTISON, M. D.

Warsaw, N. Y.

[The solution mentioned is intended to be given by the mouth. The solubility of bisulphide of carbon in water is very slight, and the water may be many times renewed before the bisulphide is exhausted. Before administering, care should be taken to see that the bisulphide has fully subsided in the bottle, leaving the supernatant water clear. So far as we know, rectal injections of water thus impregnated have not been given. They would present no advantages over administration by the mouth, except in cases of very irritable stomach.—EDS. OF THE REPORTER.]

Base-Ball Injuries.

EDITORS MED. AND SURG. REPORTER :

Sirs : In the REPORTER of July 9 the subject of base-ball injuries is taken up and quite thoroughly treated of, at least so much is said of our national game as to lead one to think that the injuries spoken of were almost miraculous in their healing. We are given to understand that the ball moves oftentimes with the velocity of a moderate cannon ball; that if it were to strike against any part of the person, the resulting injury would be of the most serious character; but that if medical science lets the injury alone, and unenlightened comrades come to the rescue, the cure will be so complete and rapid that the player can nearly always go on with the game uninterruptedly. The weak starting point is the writer's description of the ball. First, a rubber sphere; 2d, wound with *woolen* yarn; and 3d, covered with two thicknesses of leather. When "boys" we used to play "sock" with a solid rubber sphere and never were in danger of being killed, either; but then the locality attacked was not so sensitive

as hands and faces. Nothing is said about bats. But there are two reasons why balls are covered with wool. First, to make them springy and comparatively harmless, and 2d, so they will not dent and tear the bat to pieces. Bats being made of light tough wood, are easily "battered up." The fact that one man receives a "foul tip" on his chest and is killed, while another is not harmed from a whack on the head, counts for nothing. How many cases do we see and read about who have succumbed from a light blow on the chest, shocking the movement of a weakened heart, while another has his head pounded almost into a jelly without permanent injury? But that base-balls can accomplish a serious injury we cannot believe, for a variety of causes. Its weight is only five ounces; its bulk nine inches in circumference—certainly out of proportion for very great velocity. The outer surface and intermediate packing are of such a nature to obviate serious contusions. The ball *from atmospheric resistance* can only reach a certain amount of velocity with the most skillful players. The player's hands, from habit, should become so hardened as to not only catch the regulation ball "hot" from the pitcher or fellow-baseman, but even a solid rubber ball.

I had the honor to serve several years as first baseman when Capt. Kepner, a noted athlete, was pitcher, and hundreds of balls have I taken from his hand which came with all the force of his mighty arm; and to-day, although my service was "hot" while it lasted, I cannot point to a joint injured or a cut received, and although it has been several years since I held my "right foot on the sand bag," yet I will wager, that unaccustomed as my hands now are to the "horse skin" cover, I will take the "hottest" ball and not wince.

Injuries are injuries, and if a substance which has the power to break one's skull, strikes the body, serious consequence must arise, and the cure is slow, if at all. We all know that subluxations of phalangeal joints are the simplest of injuries upon which the surgeon is called to show his skill.

We have known shoemakers who could strike the bare knee with the steel head of a shoe-hammer, hard enough to crack walnuts or hickory nuts, yet without pain or injury. We have seen men, the inside of whose hands were so hard and horny that it was difficult to push a needle through the skin. Base-ball players by cultivating the art of catching a ball should become so accustomed to the work as not to feel a "hot" ball in any disagreeable manner. The inside of the hands

being naturally hard and dense, can by constant contact with a hard object, become almost insensible to pain. The ease and rapidity with which base-ball injuries are healed is proof positive of their trivial nature.

One source of injury in base-ball playing not mentioned is the careless manner in which the bat is handled by an excited player. After having made a strike, instead of dropping the bat, he often, in excitement, will throw it with such momentum that coming in contact with a neighbor, injury has resulted.

In closing, I wish to say that I have read Dr. Leuf's article with much interest and pleasure, and hope he will write again upon the game of games, this note being written merely to suggest some points which seem overdrawn.

Truly yours,

JAMES BATES, M. D.

NEWS AND MISCELLANY.

A Question of Ethics.

Last Spring, Surgeon General John S. Hamilton, of the Marine Hospital service, preferred charges to the Medical Association against Dr. Sowers of unprofessional conduct in criticising publicly, from a medical point of view, the manner of living of the President. Dr. Sowers has now preferred charges against Dr. Hamilton of having violated the association's regulations, in having shown to Ex-Representative Hazleton the charges which he was about to prefer against him (Dr. Sowers) last April. This was done, it is charged, with the full knowledge that Mr. Hazleton and his family were patients of Dr. Sowers, and was intended to lower him in the estimation of his patients.

The case of Dr. Sowers has not been formally disposed of, but the result of the investigation by the Standing Committee is equivalent to an acquittal. It requires two-thirds to convict, and unless this number favor conviction it is not deemed necessary to make a report to the association. Two-thirds did not vote guilty. A minority and majority report were prepared, and there the matter rests.

French Toilet Preparations.

In a report submitted to the Hygienic Council of Paris by Drs. Dubrisay and Chatin, the authors state that the perfumery and toilet products now sold contain so many noxious substances that it is desirable the factories should be placed under special surveillance. They give a number of instances

in support of their statement. The so-called "harmless and purely vegetable" hair dyes, they say, are all poisonous. "Progressive dyes" are ammoniacal solutions of nitrate of silver. The "instantaneous dyes" are a solution of litharge in lime water. "Eau des Fées" is a solution of sulphate of lead in hyposulphite of soda. "Eau Figaro" consists of three solutions: (1) of nitrate of silver and sulphate of copper; (2) sulphide of sodium; (3) cyanide of potassium (to remove the silver stains). "Eau des Fleurs" is composed of rose-water, 95.5; flowers of sulphur, 2.7; acetate of lead, 2.8. Passing to cosmetics, they say "Lait antiplelique" is composed of corrosive sublimate, 1.7; oxide of lead, 4.22; sulphuric acid and camphor. "Lait de Manille" is a mixture of borax, copper, tincture of benzoin, and essence of bitter almonds; "Lait de Ninon," of bismuth and zinc; "Eau Magique," oxide of lead and hyposulphite of zinc; "Eau de fleur de lys," protochloride of mercury; "Eau royal de Windsor," glycerine and oxide of lead; "Eau de Castille," hyposulphite of soda and acetate of lead. The "Poudre Pilivore de Laforet" contains mercury (?) 60 grs.; sulphide of arsenic, 30 grs.; litharge, 30 grs., and starch, 30 grs. "Epiteine" is simply sulphite of calcium, and "Antibolbos" hypophosphite of soda. Pomades against baldness all contain cantharides and croton oil.

Northeast Virginia Medical Society.

At a meeting of this society, held June 27th, 1887, Dr. Frederick Horner made an address in which he said that the success of a society depends mainly upon its officers, and that all the members ought to take a deep personal interest in the society to which they belong. He called attention to the study of inebriety as a disease.

The Northeast Medical Society has been in successful operation for ten years, meeting monthly at Warrenton, a town named in memory of the great patriot, Dr. Joseph Warren, of Revolutionary memory, and the birth-place of the late Professor W. E. Horner, of Philadelphia. Among its Fellows representing a portion of the Piedmont section of Virginia, and including the counties of Fauquier, Prince William, Culpepper, and Loudoun, are three distinguished physicians, Drs. Henry Trist and Clarkson and Dr. Hicks, late of North Carolina and Charleston. The Committee on Publication propose at an early day to publish a medical monthly.—*From a special correspondent.*

No Crown for Æsculapius.

It was expected that the tacit understanding which excludes the members of the most useful and beneficent of the professions from the peerage would come to a timely end in the Jubilee year, and that Sir William Jenner would be made a baron. However, it seems that the satirical poet wrote with some truth:

"Forbid it! forbid it! ye barons and earls;
Oh, Rank, how thy glories would fall disen-
chanted,
If coronets glistened with pills 'stead of pearls,
And the strawberry leaves were by rhubarb sup-
planted!"

—*From the London World.*

Electrolysis in Angeioma.

Dr. Julian Alvarez speaks favorably of electricity in the treatment of angioma. He uses Onimus's apparatus, the positive electrode being plunged into the tumor, while the negative is moved about over the surface of the latter.

Items.

—Dr. Packard has removed to No. 1926 Spruce Street, Philadelphia.

—"Hello, Major," said the Judge, "I haven't seen you for a week; where have you been?" "Been home sick as a dog," replied the Major. "You! Why, you are always as healthy as could be. What in the world made you ill?" "Well, I tried to follow some rules on health I saw in the papers."

—A patent medicine man has frightened a good many people by announcing, in big type, that to want to sit down after walking all day is an infallible sign of kidney disease. There are only a few people who don't want to sit down after walking all day, and most of those who feel this insidious symptom of a dangerous disease will be astonished to learn that they are not merely tired.

—A doctor in an eastern city was recently convicted of criminal abortion and sentenced to seven years' imprisonment. His defence was that he thought he was treating a case of dropsy. But he did not explain why a dropsy should be treated through the vagina.

Mrs. Foshay (to prospective nursery maid) —You are fond of children, of course? Applicant—Fond of em? I should say I was, ma'am. If I hadn't been I wouldn't a nursed my sister's nine young ones that was down with scarlet fever till every blessed one of them died, ma'am; and buried the last of 'em a week come Friday.

OBITUARIES.

DR. GEORGE LITTLE.

Dr. George Little died suddenly in Philadelphia, July 19th, from extreme prostration, caused by overwork. He was born in England about thirty-four years ago, and, coming to this country with his parents when twelve years of age, he settled in Philadelphia. A few years later he began the study of medicine in the Medical Department of the University of Pennsylvania, from which he was graduated in 1878. Since then he has practiced his profession in this city, and was well known in the locality in which he lived. He leaves a widow and two children.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the week ending July 23, 1887:

C. S. D. Fessenden, Surgeon, granted leave of absence for thirty days on account of sickness. July 18, 1887.

F. W. Mead, Passed Asst. Surgeon, granted leave of absence for thirty days. July 19, 1887.

H. W. Yeomans, Passed Asst. Surgeon, granted leave of absence for thirty days. July 23, 1887.

S. D. Brooks, Passed Asst. Surgeon, promoted and appointed Passed Asst. Surgeon from July 1, 1887, to July 21, 1887.

J. H. White, Asst. Surgeon, to proceed to Washington, D. C., as escort to an insane seaman. July 18, 1887. Ordered to examination for promotion. July 23, 1887.

R. B. Watkins, Asst. Surgeon, leave extended fourteen days on account of sickness. July 20, 1887.

G. M. Magruder, Asst. Surgeon, to proceed to Galveston, Texas, for temporary duty. July 21, 1887.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from July 16, 1887, to July 23, 1887:

Par. 13, S. O. 167, A. G. O., July 21, 1887, assigns Lt.-Col. A. Higer, Surgeon, to duty as member of Army Retiring Board Command, at Governor's Island, N. Y. Harbor, N. Y., vice Col. Chas. Sutherland, Surgeon, hereby relieved.

By par. 43, S. O. 162, A. G. O., July 15, so much of par. 1, S. O. 156 O. S., A. G. O., as directs Capt. Jno. de B. W. Gardiner, Asst. Surgeon, U. S. Army, to report for duty at Ft. Washakie, Wyo., is revoked.

Capt. R. Barnett, Asst. Surgeon, sick-leave still further expended six months on account of sickness. S. O. 162, A. G. O., July 15, 1887.

By par. 42, S. O. 162, A. G. O., July 15, so much of par. 1, S. O. 146, C. S., A. G. O., as relieves Capt. Geo. Tomey, Asst. Surgeon, U. S. Army, from duty at Ft. Monroe, Va., is revoked.

Capt. A. W. Taylor, Asst. Surgeon, now at Ft. Laramie, Wyo., is ordered for temporary duty at Ft. Robinson, Neb. S. O. 162, A. G. O., July 15, 1887.

ORIGINAL DEPARTMENT.

LECTURE.

DETAILS OF ANTISEPTIC DRESSING.¹

BY DR. J. M. BARTON,
Surgeon to the Jefferson College Hospital.

When your President invited me to your meeting, and asked me to make some remarks on this subject, I thought that almost enough had been already said and written about it, and that further argument on the subject was unnecessary, as antiseptic surgery has undoubtedly been fully accepted by the scientific world.

But as antiseptic results are only to be obtained, with certainty, by very careful attention to details, it might be of service if I were to describe in full the methods I now use; which, though perhaps not the best, give almost invariably full antiseptic results.

It will probably be best to describe some particular operation; take for instance the excision of a breast, for cancer or other tumor, at my clinic at Jefferson College.

The night before the operation the patient takes a warm bath, has clean clothing, and is placed in a clean bed. Early in the morning the axilla is shaved, the breast, the axilla and the surrounding parts are washed with turpentine, then with soap and water, and lastly with a solution of bi-chloride of mercury (1 to 1000). The entire front of the chest is then covered with several layers of cheese-cloth wrung out of the same solution. Waxed paper is placed over this to

prevent evaporation, and the patient remains in bed until the hour for operation, which is about noon.

The operations at the hospital are performed either in the clinic room, or in the private operating room; these rooms being used for nothing else, are quite separate from the hospital and its wards, are constantly ventilated, the windows being usually kept open, and only closed just before an operation. Soiled dressings are not permitted to accompany a patient into these rooms, and if they should, accidentally, are quickly removed.

In the private operating room no unnecessary furniture is permitted, one operating-table, two rolling instrument tables, and one chair being all the furniture in a very large room. There is no carpet on the floor, the walls are painted, and both walls and floor are frequently washed.

All instruments that may be needed are placed for a short time in a vessel of boiling water, and are then placed in shallow tin vessels in a three per cent. solution of carbolic acid. They are not placed in the mercurial solution, as that would quickly tarnish them and spoil their edges.

The surgeons and assistants wash their hands, wrists and fore-arms thoroughly with soap and water. After drying them they are washed in the 1 to 1000 mercurial solution, which is not wiped off.

The surgeons and assistants at the time of operation all wear clean white linen coats, fresh from the wash, which are never used elsewhere.

All sponges have been carefully prepared; those that are new have been beaten and

¹ Read before the Delaware State Association at its meeting in Smyrna, June 14, 1887.

then soaked in dilute muriatic acid to get rid of the sand, and subsequently soaked for several days in the mercurial solution. Those that have been used, have the blood washed out at once, and are then soaked for some hours in a solution of soda to get rid of the fibrin, then again washed in water, and lastly placed in a jar in the mercurial solution, with a date placed on the jar, so that they may not be used too soon.

Just before the operation, the sponges are taken out of the antiseptic fluid and squeezed dry, are then placed in a basin that has been washed with the same fluid, and covered with a towel wet with it.

At the operation no sponge is used after it is once saturated with blood, but is at once thrown aside, and does not re-appear at an operation for at least a week, during which time it has gone through the above-described process. If a sponge falls on the floor, or has laid for a moment on any place that has not been rendered antiseptic, it is at once thrown aside. The patient is now etherized, with the pad of antiseptic gauze still on the diseased breast.

The operator and assistants, after preparing their hands, are careful to touch nothing, nor to handle the patient if she struggle, nor even to touch a chair or a blanket or anything. If they should accidentally do so, the washing of the hands must be repeated.

When the patient is fully under ether, the antiseptic gauze is removed, towels are wrung out of a three per cent. solution of carbolic acid and placed all around the field of operation. They are spread over every thing, over the blanket, over the arms of the patient and under the side to be operated upon, so that a sponge or an instrument may be laid down without danger of becoming contaminated. Carbolic acid is preferred for these towels as mercury would spoil the instruments.

After the diseased gland is removed the bleeding vessels are all tied with catgut, which has also been kept in an antiseptic solution. Three knots, at least, are placed on each ligature, and both ends are cut off short. The wound is now thoroughly flushed with the 1 to 1000 mercurial solution, and for this purpose a large stone-ware jar, holding several gallons, is placed on an elevated shelf in one corner of the clinic room, with a long rubber hose attached, which reaches to the operating table and terminates in an ordinary Davidson's syringe, with which the pressure of the fluid can be increased if desired. In private practice, a rubber fountain syringe answers the purpose. Considerable time must be spent in this process, especially if it

should have been an infected wound previous to operation, as for instance, an open suppurating joint, for which amputation or excision has been performed.

After the hemorrhage has been controlled, and the wound has been thoroughly flushed with the Mercurial solution, a rubber drainage tube, suitable for the case, is taken from the jar filled with Mercurial Solution 1 to 1000, in which they have been kept, and laid in the bottom of the wound; the flaps, if there be any, are brought together with catgut. One stitch at the end is carried through the drainage tube to keep it in place, and then a continuous suture of catgut is made from one end to the other. If the wound is a small one, like that made in trephining, or in operating for strangulated hernia, a few large threads of catgut are laid in the bottom of the wound to serve for drainage.

The closed wound is now dusted with Iodoform and covered with folded pieces of common cheese-cloth, large enough to fully cover it. These should be eight or ten layers thick, and should be thoroughly saturated with the Mercurial Solution. In the Hospitals, large specimen-jars are kept filled with such pieces of cheese-cloth lying in the Mercurial Solution. Over the wet cheese-cloth, a piece of mackintosh, slightly larger than the cheese-cloth, or a piece of rubber, or of waxed paper is placed. A strip of adhesive plaster holds this in position, and then some oakum, jute or cotton, kept in place by a bandage.

A wound from an amputation of a limb is dressed in precisely the same way.

On the following day, if there is reason to suspect that there has been any oozing, and there generally is some, the dressings are removed; the wound is not washed nor touched, only fresh mercurial cloths laid on, and the external dressings re-applied. At this time the drainage tube may be removed, though this is rarely done.

From this date on the dressings are left undisturbed, unless the temperature goes above 101°.

At the end of about ten days the wound is looked at; if it is solidly healed and the ligatures have been absorbed, the external portions of the stitches are brushed off. The drainage tube is found loose, and is removed, if of rubber; if catgut has been used, this will have been absorbed.

The patient can be discharged a few days later.

It is nothing unusual to send out a solidly healed amputation of the thigh in 18 days,

an amputation of the arm or leg in 14 days, a patient after the removal of a large breast tumor in 14 days, and an excision of the hip in a month. These patients frequently have not had one drop of pus form. They are not ill and do not require sick diet. Three days after an extensive operation they are often able to eat solid food. They are not tortured by daily dressings. Septicæmia or pyæmia rarely develops from such an operation.

In cases of severe compound fracture, the surgeon, assistants, and patient are prepared as before, the wound is enlarged, small and loose fragments of bone are removed, and the larger fragments put accurately in position. If they do not readily remain in place, they are wired with heavy silver wire. All hemorrhage is controlled by catgut ligature. The wound is then thoroughly flushed again and again with the mercurial solution, the lips of the wound are held together, while with a syringe the solution is pumped in so that all parts may be fully distended and brought in contact with the fluid.

In a case of compound fracture, where supuration had already occurred, and where the temperature was 103° , I have succeeded by this method in at once bringing the temperature to normal and checking all further supuration. After the wound is flushed, drainage tubes are introduced, the wound closed and dressed as before described; appropriate splints or apparatus must then be applied, as though the case was one of simple fracture.

In laparotomies I prefer, when it is possible, to perform the operation at the patient's home; though I have opened the abdomen several times in the hospital with success.

The patient is prepared as before; bath and clean clothes the night previous; abdomen shaved, washed with turpentine, soap and water, and carbolic solution. When operating in a private house, I choose a room where there is a good light, and, a few days before the operation, I have the carpet, the pictures, and most of the furniture removed, and the floor and paint scrubbed.

The instruments are prepared as before, and the field of operation surrounded by cloths wet with carbolic acid. When the abdominal cavity is reached, I try to make the operation an aseptic rather than an antiseptic one.

If the abdomen to be opened is free from germs, I try to free my sponges first from germs, and next from the antiseptic, before using them.

Carbolic acid, $2\frac{1}{2}$ parts to the 100 of boiled water, is used to wash the hands and to place the instrument in.

The sponges are wrung out of the same

solution, and then out of boiled water. If there is much bleeding in the abdominal cavity, and a careful toilette of the peritoneum has to be made, the sponges, when saturated with blood, are washed in boiled water, then in the carbolic solution, and lastly in clean boiled water, before being returned to the scene of operation.

If any septic material has entered the peritoneal cavity, as, for instance, when the intestines have been wounded by a stab or gun-shot wound, sponges wrung out of a 1-10,000 mercurial solution are used. If much of the septic material is present, it is customary to flush the abdominal cavity with this weak mercurial solution. This is done by emptying several basinsful of warm mercurial solution, 1 to 10,000, into the cavity, while the wound is held open by an assistant. Then, turning the patient on the side, the fluid escapes, while the bowels are prevented from protruding by the hands of an assistant.

If the abdominal walls are fat and apt to suppurate, or if their natural tension be not lessened by the removal of any growth, I close the peritoneum with catgut, and the external wound with deep and superficial sutures. On the contrary, if the walls be lax, as after the removal of an ovarian cyst, and if there be but little fat, I close the wound in the usual manner with silk sutures, passing through the abdominal wall and including the peritoneum.

Mercurial gauze is placed over the incision, and, as there is little probability of any oozing, this is left undisturbed, until either the temperature rises or the time arrives for removing the stitches.

COMMUNICATIONS.

PRELIMINARY REPORT OF A SERIES OF CASES OF PURPURA TREATED BY GASEOUS ENEMATA, WITH REPORT OF CASES TREATED BY OTHER METHODS.

BY WM. DUFFIELD ROBINSON, M.D., PHYSICIAN
TO EASTERN STATE PENITENTIARY,
AND HENRY SKINNER, M.D.

During the last two years there have occurred twenty-three cases of purpura in its different forms in the Eastern State Penitentiary. During the same time we have had but two cases of the disease in general practice outside of the prison. The one point especially noticeable in the aetiology, is that in every case there has been, for rather pro-

longed periods, an almost entire avoidance of meats in the dietary of the subjects. One pound of good well cooked meat, beef or mutton alternately, is given daily to each convict in the Penitentiary. On Sunday pork is the meat served; a bountiful and varied supply of vegetables is also daily served. These are well cooked and given in a sort of stew made in the liquor in which the meat has been boiled. Sauer-kraut, tomatoes, apples, stewed peaches, cabbage, potatoes, beets, onions, parsnips, soup, herbs, etc., etc., are abundantly supplied to every convict in sufficient variety every day. It can be seen by this that a deficient or insufficiently varied food cannot be a cause of the disease here. In spite of a good dietary, clean and well cooked and served, and sufficient air and exercise to induce appetite, it is noticed as stated, that the victims of this disease here for some time before and during its continuance, had rather an abhorrence of all meats, and had lived on bread, coffee and vegetables. There was, before the development of the disease, in no case any indication of much anemia or reduction in physical health. The development was rather sudden, in each case being preceded by general malaise and lassitude, loss of appetite, etc. They all had requested a tonic, saying that they felt run down and altogether out of sorts. Elixir of iron and gentian was usually prescribed.

In from four to fourteen days after the first complaint, the purpuric spots began to appear on the arms and limbs. With the appearance of the spots a condition of excessive anemia became very evident. Three of the cases occurred in insane subjects (delusional lunatics) two of whom died of the disease.

CASE I.—Male, aged 26 years, received in good mental and physical health, had served about forty months of a five-years' sentence, and had been in fair health. He had long been a masturbator to an injurious degree, and about this time began to look badly, lose flesh, and show a weakness of his mind, demonstrated in morbid suspicions and delusions, so very frequently noticeable in those long addicted to this habit. He claimed that the meat was bad or poisoned. He could not be induced to eat it, and therefore lived on bread, coffee and vegetables. In a few weeks the purpuric spots began to show, and he ran down rapidly in health. His mind became more deranged. The purpura increased, spots as large as a man's hand appearing on different parts of the body. Anemia was very marked, puffing cedema was noticeable in the extremities, slight hemor-

rhages occurred from the gums, nose and bowels. All the symptoms grew gradually worse, till death, which occurred three months after the first appearance of the disease. The autopsy showed the cadaver to be quite bloodless, with serous effusions into the brain cavities, but no other noticeable brain lesion. Limbs and face quite dropsical. Kidney and liver healthy. Open-air exercise and stimulants were the only remedies this man could be induced to use.

CASE II.—Male, aged 44 years, had served a number of years in prison before reception here. History was very similar to Case I. He was a masturbator, became insane, avoided meat, etc., and was before death at least one-fourth covered with the purpuric spots, would not take medicine. Died after four months of the disease and autopsy revealed same condition as found in Case I.

CASE III.—Female, aged 26 years, single. This case occurred in private practice. A young lady, in affluent circumstances, had been an excellent specimen of perfect health and womanhood. Previous to this attack, she had nursed a near relative through a long siege of Bright's disease, during which she was closely confined to the house. She had irregular meals and sleep, and was quite tired out. She ate but sparingly of meats for some weeks, and for six weeks previous to the attack did not eat any meat at all. After the death of her charge she did not recuperate well, complaining most of general weakness and exhaustion. She was pale, but had not lost much weight, though her flesh had become flabby. At this time she began feeling quite badly, and expressed herself as having caught a general bad cold, but knew of no indiscretion or exposure to account for it. She kept her bed, and full doses of quinia following a stimulant to the biliary secretions were administered. Temp., 102 $\frac{3}{4}$; pulse, 128. This continued with little change for four days, when a profuse crop of purpuric spots appeared. During their development there was much nervous weakness and excitement, fever, rapid pulse, and loss of appetite. The cessation of the appearance of the first crop was followed by a general improvement in temperature, pulse and in the feeling of the patient. Iron, quinia, strychnia, phosphoric acid, light wines, massage and general faradization, constituted the treatment. A rheumatic element in the disease rapidly developed and a new crop of purpuric spots appeared every few days. Proper diet was most carefully looked after. She gradually grew worse by relapses, and in a month was in a very low condition indeed. At

that time, during temporary improvement, she was removed to the sea-shore for a couple of weeks, but did not seem to gain much. After her return home she slowly improved, the crop of purpuric spots being farther apart and smaller. After four months the menstrual functions became re-established, and at present writing, after five months, she is almost cured. The same treatment was pursued in Cases IV, V, VI, VII, VIII, IX and X. They are all convicts and were treated with the same medicinal remedies as were used in Case III. Cures resulted in all in from three to six months, except in case VII, in whom the anemia was very marked for fully a year. The foregoing convict cases all occurred during 1886. In the present spring a selected series of cases of phthisis were placed under treatment by Bergeon's method of gaseous enemata. We noticed that one of our worst cases of phthisis had a purpuric spotting, covering both limbs and thighs and that it improved very noticeably from the beginning of gaseous enemata. This led us to select some cases of purpura then in the prison and to place them under the treatment by gaseous enemata. Of the six cases we report, three were free from other diseases. In all, the improvement was immediate, marked, and rapid. Two are entirely cured of the purpura after four weeks' treatment: one of these was a consumptive and one was without any other complicating disease.

CASE XI.—Aged 32 years, white, male. The purpuric spots appeared on this man about April 15, being very thickly distributed over the arms, thighs and legs, and penis. He had none on the trunk. They varied in size from that of a pin-head up to half a dollar. It was the first attack of the disease he has had. It produced systemic disturbances; he had headache, felt languid and lost his appetite. He did not care for meats, and rarely ate any. The cervical glands were swollen. The gas treatment was commenced June 11 for phthisis, and is still being used. He has had no other treatment for the purpura. He has wonderfully improved in every way. The purpura has been entirely cured.

CASE XII.—White, male, aged 33 years. The disease commenced about five weeks ago, and was most marked about the ankles, and extended from this articulation up the legs for about five or six inches. The extravasations had coalesced and the ankles were of the color of claret, very painful and much swollen, and the hemorrhagic spots indurated. There was no general effect, the patient feeling well, though standing on his feet caused pain. He has enlarged cervical

glands, does not eat much meat, was taking tincture of chloride of iron, which did not benefit him. He was put on gas treatment, and is improving fast and will probably soon be well. The swelling has disappeared, and all the extravasated blood has been absorbed.

CASE XIII.—White, male, aged 44 years. This was his first attack, and began about May 1; he had loss of appetite, languor and headache, and said he felt very badly all over. The cervical glands were enlarged. He was put on Fowler's Solution, and said that he grew worse under it. He cannot eat meat. The general effect of the disease was well marked in this case. It was about five days before the patient could retain the gas. The ankles were greatly swollen and indurated and the hemorrhagic patches entirely covered them. They were of purplish color. Under the gas treatment for about a month he has improved in every way, looks better and feels better. The swelling in the lower extremities has disappeared, and the blood has been absorbed, leaving only some of the coloring matter.

CASE XIV.—White, male, aged 22. Has enlarged glands in the groin, is in very poor condition generally, and would never take much gas, claiming that he could not hold it. It is his first attack of purpura, and extends over the whole body excepting the hands, face and feet; and it is of the variety known as purpura papulosa or the small papules, round the hair follicles. He does not eat meat and has had no treatment but gas. He has not improved much.

CASE XV.—White, male, aged 22. Has had purpura about three months, this being his first attack. Cervical glands are greatly hypertrophied, and he has rheumatism badly. The purpuric spots were on the legs in large numbers and were about one-fourth of an inch in diameter; also one large extravasation on the inside of the thigh, about four inches long and two and a half wide. He says he is not much of a meat-eater. Under gas treatment his purpura has been cured and his general health greatly improved.

CASE XVI.—Aged 29 years. The present is the fourth attack of purpura in two years, and commenced about April 1 of the present year. It began with headache, languor and general malaise. The purpura is very extensive and there has been no improvement until the commencement of the gas treatment. The spots are large and numerous. No enlarged glands. Previous attacks were cured by long continued course of tonic treatment. He for years has avoided meat in his food. He is rapidly improving with the gas.

PURPURA HÆMORRHAGICA AS A COMPLICATION.

BY ENOS T. BLACKWELL, M. D., OF CEDARVILLE, N. J.

It is a fortunate circumstance that thoughtful physicians, on witnessing complications of disease which are unfamiliar from their rarity, send their description to medical journals for their submission to the profession in general.

Dr. Nefe, of Whetstone, O., has done a meritorious service by publishing an account of purpura as a sequel of pneumonia. While this is quite unique, authors tell us that "there is no form of disease with which pneumonia may not be associated, especially when the powers of resistance have been enfeebled by previous illness."¹

Dr. N. has intimated a desire "to see such cases written upon, so that we may know what has been tried and with what success."

The description and treatment of purpura hemorrhagica are given, I suppose, by most systematic medical authors. Drs. Watson and Flint each give it a short notice; and excellent portrayals of it are to be found in "Wood's Practice of Medicine," and in "Wilson on the Skin." "The Handbook of Diseases of the Skin," edited by Von Ziemssen,² gives perhaps the best statement, and embodies the most recent observations. The causes, characteristics and treatment are given with more or less fullness by each. In a recent case treated by me, the purpura was clearly a result of the degeneration of the blood. The disorder in which it was an incident appeared to be a relapsing peritonitis, adynamic in its character, and having many aspects of infectious fever. The petechiæ, which appeared about the shins, at the close of the illness, were of a clear violet color, without perceptible elevation, and about one line in diameter.

It is a pity that so clever an observer as Dr. Nefe should speak of his case as "cerebral pneumonia." As the brain symptoms were doubtless the result of elevated temperature, which is incidental to the disease, it seems unnecessary to burden nomenclature with this additional title. The inscription of Professor Pepper's paper in the first number of the present volume of the *REPORTER* affords a valuable hint in this direction. In addition are these prominent remarks by Juer-

gensen:³ "It would be difficult to assign any reason why these symptoms, which are common to all febrile conditions, should be ascribed in pneumonia to any other cause than the fever. And yet some have distinguished one form of pneumonia as 'cerebral,' 'meningitic,' etc., on account of the strong predominance of the cerebral symptoms . . . the brain symptoms depend essentially on the fever.

Again: "We might as well deny that alcohol will intoxicate, as reject the evidence that an increase of temperature will produce cerebral symptoms."

WOUND OF PERINEUM AND URETHRA; RETENTION OF URINE; TRAUMATIC STRICTURE; ASPIRATION OF BLADDER; RECOVERY.

BY O. L. ABBEY, M. D., OF WATERFORD, PA.

H. L., aged 13 years, of Union City, Pa., in 1879 was thrown over the head of a horse, and the horse jumping over him, struck him with one foot at the attachment of the scrotum to the perineum, making a bad wound.

Five hours later I attempted to empty the bladder with a catheter, but did not succeed. The next forenoon, with the assistance of Dr. Sherwood, I chloroformed the boy, after we had each tried in vain to introduce a catheter; but even when he was under the anæsthetic we had no better success. In the afternoon it became evident that the bladder must be relieved. So I procured an aspirator, and in the evening I aspirated the bladder and drew out the urine. I used a Peaslee's aspirator, and blistered my hands in the operation. I aspirated the bladder for two succeeding days.

The fourth night after the injury, a fistulous opening formed in the urethra at the seat of the wound, and the urine dribbled through it and emptied the bladder. A traumatic stricture was formed, through which we were unable to pass the smallest catheter of any kind. All of the urine ran away through the fistulous opening as fast as it was secreted.

The opinion of some of the oldest and best surgeons of the county was solicited. One recommended crowding a small silver catheter into the bladder and letting it remain, hoping the wound would heal over it. In the meantime the swelling was subsiding,

¹ Juergensen: art. croupous pneumonia. Ziemssen's *Cyclopædia*. Vol. v. 106.

² New York: Wm. Wood & Co.

³ Ziemssen's *Cyclopædia*. V. 106, 102.

and with the opinion of Dr. Sherwood coinciding, I concluded that I would wait and not interfere until we were obliged to. I also had the opinion of Dr. Bonsteel, of Corry, to that effect.

After the swelling was gone and the wound was nearly healed, I discovered that the bladder retained the urine for awhile, and when the boy urinated, a little passed the whole length of the urethra. The fistula finally closed entirely, and the urine seemed to act upon the stricture as a dilator. The young man has never had any trouble with it since.

Twenty-three years ago I lost a patient with acute inflammation of the prostate gland, who, I think, might have been saved by aspirating the bladder.

NOTE ON THE USE OF ANTIPYRIN IN THERMIC FEVER.

BY MORRIS J. LEWIS, M. D.,

Physician to the Episcopal and the Children's Hospitals, Philadelphia.

In antipyrin we possess a very valuable addition to our means of treating thermic fever. This should be given hypodermatically in simple solution, as follows:

R Antipyrin..... 5 ij
Aq. dest. q.s..ad.....f 3 ss
M.

℥ xx of this solution contains about gr. x of antipyrin; and this amount, or in severe cases double the quantity, should be injected beneath the skin as soon as it is possible to do so. This solution should be kept on hand during the heated term by all those who may be likely to be called upon to treat heat-stroke, for by the timely administration of this drug lives may be saved that otherwise would be lost; for much time is often lost in conveying the patient to a place of safety. This applies especially to patients before they are taken to the hospitals.

A very small vial may be carried in the pocket with the syringe, holding a sufficient quantity for any emergency.

Compressed tablets of 5 or 10 grains could easily be prepared, and readily dissolved in a few moments in water.

The hypodermic use of this drug is far preferable to its internal use, even if the patient should be able to swallow, or to its use by injection into the bowel as reported by Dr. Orville Horwitz, (Transactions of the College of Physicians, 1885), on account of the greater certainty of its speedy action. The possible danger of collapse after its free use

should be borne in mind, but the immediate great danger of the hyperpyrexia far outweighs this possibility.

As soon as possible the treatment by the bath, wet pack or rubbing with ice, should be employed, as it will not do to trust to antipyrin alone; although subsequent injections should be given should the temperature not show signs of falling, or should there be a decided rise after the temperature has been reduced by other means. This drug should be considered as a most valuable adjuvant to the ordinary treatment to be mainly relied upon.

Antifebrin can not be used in this way on account of its insolubility.

A SIMPLE WAY TO APPLY FLUIDS TO THE NASAL CAVITY.

BY CHARLES W. DULLES, M. D.,
OF PHILADELPHIA.

In practice it is sometimes far from easy to make application of fluids to the inside of the nose and the posterior nares. Douches are not quite safe, because the fluids are sometimes forced into the Eustachian tube, and set up an inflammation of the middle ear. On the other hand, it is very hard to teach patients how to draw a fluid up into the nose without producing strangling or coughing.

A way which I have found very successful is the following: Take a test tube about four inches long and half an inch wide, and place in it the solution to be used. Open the mouth and breath through it. Put the open end of the tube into one nostril, catching the rim against the ala so as to make a good fit. Then bend the head back, and raise the closed end of the tube, so as to *pour* the fluid into the nostril. All the while keep breathing through the mouth. The fluid will now run into the nose, pass back to the naso-pharynx, and can be made to go around behind the septum and on top of the soft palate, and come out of the opposite nostril. By moving the head about in various directions, the fluid can be made to reach any point in the nares, in front or behind, and to remain in contact with it as long as may be desired.

Any one who will try it will be surprised to find how thoroughly and easily this can be done.

Of course, all fluid applications to the nares must be well warmed and of a proper specific gravity. If, for example, Dobell's Solution be warmed to about 100° (Fahr.),

and used in this way, it will be found a most soothing application. The quantity to be used may easily be as much as such a test tube as I have referred to will contain. And it may be filled several times and used again and again at a single sitting.

The method just described may not be new to others, but it is new to me; and I publish it for the benefit of those who are not acquainted with it.

HOSPITAL NOTES.

MEDICAL DISPENSARY OF THE UNIVERSITY OF PENNSYLVANIA.

Chronic Rheumatism—Treatment by Tonics. Reported by M. HOWARD FUSSELL, M. D.

Mary F., age 32, married, good family history and habits, presented herself at the Dispensary, August 19, 1885, with the following history:

Three years previously, had a prolonged attack of chills and fever; two years previously, suddenly attacked with severe pain and swelling of almost all the smaller joints, especially of the fingers and toes. This resisted treatment, and the ailment gradually involved the larger joints.

At the time of her appearance at the University, she was almost helpless, owing to the extreme pain and swelling in the great number of joints, large and small. She was pale, emaciated, and the picture of distress; appetite poor.

She was immediately put on an emulsion of cod liver oil and syr. of hypophos. of lime, with a mixture of iron and arsenic: tr. ferri chlor., f 3j; liq. arsen. chlor. f 3 ss. 15 drops t. d.

She returned in a week, better. The treatment was continued without alteration until October 15, 1885; at that time she expressed herself better than she had been since the beginning of her illness.

She made frequent visits to the dispensary for one year; for the greater part of the time the oil was taken, but the arsenic was discontinued after four months' use.

At the present writing she has scarcely any pain, is able to do her housework, has good appetite, and looks the picture of health. Save for occasional outbreaks of the trouble in the phalangeal joints, she would consider herself entirely cured.

This is a striking example of a large number of cases that yearly present themselves at the hospital. They are all classed under the comprehensive title, chronic rheumatism.

Many have gone the rounds of doctors and dispensaries, have received ounces of iodides and salicylates, but no permanent relief. Many are in need of tonics, such as those used in the case reported, and will recover without a single (strictly speaking) anti-rheumatic remedy.

Build up the strength of the patient, and nature will take care of the rheumatism.

SOCIETY REPORTS.

CHICAGO MEDICAL SOCIETY.

Stated Meeting, Tuesday, July 5, 1887.

The President, W. T. BELFIELD, M.D., in the chair.

DR. E. WESTON reported

"Cases of Synovitis of the Knee Joint."

Synovitis, though a surgical disease, is one which the general practitioner often treats—is often compelled to, if he have a country practice—and there is no reason why he should not treat it well and successfully.

A slight synovitis may recover rapidly without treatment, and so these cases get well when treated with a poultice, or when painted with tincture of iodine. But the physician who makes this his routine practice will not have many "flattering successes," and the number of cripples in his neighborhood may be monuments to his want of thoughtful attention.

I have four cases of synovitis of the knee to report. Not that they present points of peculiar interest, but to emphasize their importance, even though I disclose my own mistakes in doing so:

CASE I.—A. B., Irish, aged about 50, laborer. I met him on the street Jan. 1, 1885, when he told me he had pain in his left knee; that he did not know of injuring it in any way. Having a physician's dislike for using "all out doors" for his office, and being consulted wherever he chances to meet a would-be patient, I gave the man little attention, and advice of a very general nature. One week later he sent for me. I found him in bed suffering severe pain, knee distended with fluid in joint cavity, leg flexed. He refused to have the fluid evacuated, or even to have his leg put on a splint, although I told him plainly of the probable consequences of not doing so. Then instead of leaving the case, I allowed him to be his own physician, while I continued to make daily visits and suggestions.

I have no full notes of the case, but it went from bad to worse. Abscesses formed in the thigh, which were opened as they developed, drainage tubes were passed in various directions, the limb becoming honey-combed by the burrowing pus. The cavities were frequently syringed with carbolyzed water and the limb kept on a pillow of oakum. He was given a nourishing diet, with stimulants and tonics. But he gradually lost flesh and strength, his temperature increased, and on the 1st of March he died of sepsis and exhaustion.

CASE II.—C. D., American, aged about 45, by profession a lawyer. I saw him first March 4, 1886, when he told me his left knee had pained him quite constantly, but not very severely, for about ten days. He thought he had taken cold in it while sitting at his desk, under which he had felt a draught. I found the knee moderately enlarged, the joint distended with fluid, and hot and painful. I ordered him to bed, and had an anodyne liniment and warm fomentation applied.

This treatment was continued for three days without benefit, when I opened the synovial cavity with a bistoury and evacuated about eight ounces of light straw-colored, probably nearly normal, synovial fluid. He was at once relieved of pain. The limb was put on a well-padded posterior splint, and an elastic bandage was applied. The fluid gradually reaccumulated, and in four days the joint was again full, hot and painful. I now aspirated it, and reapplied the bandage. There was again a slight filling, but not sufficient to necessitate opening. The patient steadily improved, and in a few weeks had perfect use of the joint.

CASE III.—E. F., a Swede, aged 25, painter. Feb. 19, 1886, at noon, while on his way to work he fell, striking his right knee on the ice. It caused him severe pain for a short time, but he worked the whole afternoon, standing on a step ladder, without much discomfort. At night the knee began to swell and pain him intensely. When I saw him the knee was hot, very painful, and moderately distended, and the leg was flexed. A liniment composed of opium, aconite and menthol was applied, with warm fomentation, and opium was given internally. No improvement taking place, and the joint becoming much distended, on the 22nd inst. I opened it with a bistoury, letting out a large quantity of blood-colored fluid. He was at once relieved of his intense pain. He made a steady recovery, and in about two months had perfect use of the joint.

CASE IV.—S. H., aged 38, a carpenter. He had been at work on the outside of a building most of the winter, and of late had been obliged to kneel on scaffolding a good deal. When I saw him on Feb. 3d, he told me his left knee had been painful and getting stiff for some time. It was then painful, and contained a small amount of fluid. I could not convince him of the importance of giving it rest. I saw him occasionally during the following weeks, during which he was working about and simply using a liniment. On Feb. 11, the condition of the knee being decidedly worse, I told him unless he was willing to give me absolute control of the case, I should do nothing more for him. He was unwilling to submit, and I did not see him again for four days, when he sent for me. The joint was now moderately distended, and the patella floating. I applied a posterior splint and elastic bandage, and the patient went to bed. Three days later, the joint being very full, I opened it with a bistoury, letting out a quantity of apparently unchanged synovial fluid. Immediate relief followed, and the bandage was reapplied. The patient was given quinine and iodide of iron, and the kidneys and bowels were kept active. But the improvement was not permanent. The joint slowly refilled, and in three weeks it became necessary to evacuate it. This time I used the aspirator, and an accident happened which I am quite sure will not occur to me again. Being ready to introduce the needle, I asked my friend, who was assisting—a most careful and intelligent physician—to exhaust the aspirator bottle. All being ready, I passed the needle into the tissues until the opening near the joint disappeared, when I requested my assistant to turn the stop-cock, and as he did so I thrust the needle into the cavity of the joint. I was startled by a shriek of pain; and I have rarely seen such an agonized expression on any face. The muscles of the leg instantly became rigid and prominent, and the joint increased in size, but no fluid appeared. Fortunately the probable cause of the trouble at once occurred to me. The bottle had not been exhausted, but filled with compressed air. The needle was withdrawn, the aspirator made ready and the fluid evacuated as intended. The air which had been driven into the joint bubbled out with the liquid. But the cellular tissue of the thigh contained air which could be felt for two weeks, by which time it had disappeared, leaving no ill effects. Apparently the joint was not injured by its forcible distension, though in four days it had become filled again, and I

withdrew with the aspirator fluid of the same appearance as before. In just one week, the other knee having become similarly involved, and the joint cavity very full, I aspirated it. From this time the patient steadily improved, and he made a perfect recovery.

I have intentionally omitted to speak of the anatomy of the knee, or of the pathology, diagnosis and classification of the cases I have briefly reported. But it would seem proper to treat them by pressure, absolute rest, and early, and if necessary repeated evacuations. Barwell, whose reputation in the treatment of diseases of the joints is certainly second to no man's, says: "If the inflammation be sufficient to cause considerable secretion into the joint, producing marked fullness of the sac, the synovial membrane should be punctured * * * to relieve the tension."

Howard Marsh, in his work on "Diseases of the Joints," says: "It is now well known that matter, whether connected with acute or chronic arthritis, may be safely evacuated, with the result that the severe suffering, the prolonged fever, the wide and destructive burrowing, and the formation of sinuses, which were the common rule only a few years ago, can be generally avoided."

DR. G. J. TOBIAS: I think the paper is a very good one and the cases reported interesting. The doctor states that in two cases he made an incision before he aspirated; I would ask why he did it, why not try the aspirator first? The accident spoken of has occurred before in this city, that of compressing the air in the bottle, instead of pumping it out and producing a vacuum, thereby causing compressed air to be forced into the joint cavity with some times most serious results. Would it not be a good plan to have some basin or small receptacle at hand containing water, to try the aspirator first and see that it is in proper working order? I wish he would also tell us more fully how he used the posterior splint and whether he padded it, the material used for bandage, etc.

THE PRESIDENT: I take it for granted that Dr. Weston took the ordinary cleanly and antiseptic precautions before incising the knee-joint. Most of us would be inclined to use the aspirator before making an incision, since it is a common observation that after the knee-joint has been aspirated once, twice, three times or more, resolution has occurred and the functions of the joint resumed even when the fluid was purulent. The accident in the use of the aspirator reminds me of one of which I am personally aware as occurring in this city, and which had a more unfortu-

nate termination than in Dr. Weston's case, where most of the air got into the tissue outside of the joint. In the case to which I refer the stop cork was not turned until the needle had entered the joint, and in three minutes the patient was dead.

DR. E. B. WESTON, in closing the discussion, said: I used the bistoury instead of the aspirator because it was more convenient at that time. The bistoury has been used a good many times; but I don't pretend to say it is better, perhaps it is not so good; but in my case it was a matter of convenience. The cases did well. The posterior splint was well padded with cotton. I used for the splint, heavy sole leather. An elastic bandage, or rather a flannel bandage, was used below the knee and on the thigh, and a rubber bandage to make the pressure over the knee-joint. Of course the aspirator should have been tested. The mistake should not have occurred. And yet no injury was done by the violent distension of the joint, or by the air which entered it.

DR. WILLIAM T. BELFIELD reported

A Case of Mercurial Necrosis, with Specimen.

The case of mercurial necrosis which I wish to mention is that of a young man, apparently in excellent health, who seven years ago contracted a chancre, which was followed by the usual symptoms of constitutional syphilis. He was treated by a regular physician in an eastern city, and for a year and a half had the usual history of a healthy man contracting syphilis—mucus patches, occasional rashes on the skin, etc. After about two and a half years, during which time he was under constant observation, and much of the time taking medicine, he had no further indication of constitutional syphilis. It went along that way for about four years. Over six years after the contraction of the chancre, he noticed a slight lump on the instep of the left foot which gave a little pain when he wore tight shoes. Fearing this might be an indication of the return of the disease, he went to his physician who prescribed syphilitic treatment. He ordered the young man to take a pill of one-fourth grain of yellow oxide of mercury three times a day. The patient, who was naturally anxious to overcome any taint that might remain in him, followed the direction faithfully, and for six months took one of these pills three times a day. At the end of this time his mouth became sore. About ten days after he first noticed the soreness of the mouth, being then in Chicago, he was directed to see me. At that time his gums were quite soft and spongy,

his teeth felt loose and he could not bite bread with any comfort. On the left side the alveolar process of the upper jaw was exposed for about three-fourth of an inch in length and one-half inch in vertical breadth. The three molar teeth in that portion of the jaw were decidedly loose. The hard palate corresponding to that part of the alveolar process was swollen, and there were the usual symptoms of subacute periostitis. He was merely ordered to discontinue the mercury, to use a simple mouth wash and to take iodide of potassium. In the course of ten days the portion of the jaw exposed was so loose that it could have been removed without much difficulty, but the patient, flinching from the slight pain this would cause, declined to have it removed and worked at it with his fingers until three weeks after I first saw him, he pulled the piece away. In the meantime he had lost three sound molar teeth. The piece is quite small, only large enough for the insertion of the three teeth, but it is of some interest. The upper surface of it is the floor of the antrum. During a part of the time, the cheek bone was swollen and tender; but no abscess formed.

It may be questioned whether this necrosis was mercurial or syphilitic. The man unquestionably had syphilis seven years ago, but a little consideration shows that this necrosis was not syphilitic. In the first place, for four and a half years he has had no indication of syphilis; the little hardening of the instep, for which he took the mercury, still persists and is evidently not of syphilitic origin; furthermore, there was thickening and softening of the gums and loosening of the teeth, which was due to the mercury; and, lastly, while syphilis may cause necrosis of the long bones and of many other bones in the body, yet it rarely causes necrosis of the inferior and superior maxillary; while mercury causes necrosis in these bones with especial frequency.

Dr. Belfield said, in reply to a question that the patient had not been salivated during the time of treatment so far as could be remembered.

DR. JOSEPH HAVEN exhibited

A Mechanical Support for Maintaining the Lithotomy Position.

The position most favorable for the majority of the operations on or about the perineum is that which is known as the lithotomy position: the patient prone upon the back, thighs sharply flexed on the abdomen, knees separated. For the patient to maintain this position unaided, is a difficult pro-

cedure, and when under an anæsthetic an absolute impossibility. Hence the necessity for assistance in some form. The usual custom is to intrust each limb to an assistant to hold during the operation. To this procedure there are some objections.

First, it increases the necessary number of assistants by at least two. Usually the patient, if not the whole household, is dreading the operation with nervous anxiety, and the sight of a number of assistants or an unnecessary display of paraphernalia does not tend to quiet their fears or relieve their anxiety. Hence operations at the house should be conducted with as little display as possible.

Again, any one who has assisted in holding a patient in the lithotomy position for an hour or so, knows that it is a tiresome undertaking.

Again, emergencies are continually arising where the assistants are called upon to render other assistance, as from their proximity to the operator they are in the way of others, and are called upon to pass instruments, wash sponges, etc., thereby neglecting their own work, and the falling of the patient's foot in the operator's lap does not tend to better the results of the operation or improve the temper of the operator. Consequently, it is not strange that various appliances should have been improvised by which the patient could be held in the proper position.

My attention was first called to this subject some six or eight years ago. The operation was for the closing of a lacerated cervix. The operator brought with him an apparatus made of three boards, about four feet long, joined on the sides by hinges. When the side pieces were raised and fastened by hooks the whole formed a sort of trough in which the patient was placed and a harness arrangement bound each limb to the corresponding side piece. While the apparatus worked well upon this occasion, there are objections to it.

In the first place, it required too long a time to extricate the patient from the apparatus.

Secondly, the effect of putting together such a contrivance in the sick room might be similar to the building of a scaffold in the presence of the condemned.

Thirdly, blood stains are not easily removed from wood, and should there be any septic influence in the case, this would be readily absorbed in the pores of the wood; and I doubt the advisability of using a wooden apparatus in repeated operations in close proximity to open wounds.

In a work entitled "Minor Surgical Gynæcology," by Dr. Paul Mundé, the author speaks favorably of an apparatus designed by Dr. Hamilton, of Harrisburg, Pa., which he styles "Hamilton's Gynapod." This consists of a piece of wood upon which the buttocks rest; from this arises on either side an arm surmounted by a crutch which supports the knee. While being more simple than the apparatus previously described, some of the same objections hold good in this case. Again, as the limbs are not fastened in any way, it allows too much freedom to the feet. This will be particularly annoying if the operation be a trivial one, not requiring the administration of an anæsthetic.

If then an apparatus for this purpose is of service in these operations, what are the essential requirements?

First—It should be so constructed that it can be instantly removed, if emergency should arise.

Second—It should be of a material which will admit of its being thoroughly cleansed and disinfected.

Third—It should secure the patient firmly, and at the same time be as simple, light and easy of transportation as possible.

Acting upon these thoughts, I had made, two years ago, an apparatus based upon the same principle as the one which I shall show you this evening, namely, a light nickel plated bar provided with a hinge in the center, allowing it to be folded up when not in use. This bar passes under the knees of the patient, holding them flexed on the abdomen by means of a band of webbing which passes around the shoulders of the patient; the webbing having a strap and buckle allowing the band to lengthen or shorten according to the size of the patient. Bands of the same material at either end of the rod securely hold the limbs below the knee; every strap being attached to the rod by means of a snap catch, which can be instantly disengaged if occasion so demands. A rod attachment for holding a fountain syringe completes the outfit. The whole apparatus when not in use fits into a case eighteen inches long, five inches deep and four inches wide.

In this connection it becomes my duty, and at the same time at pleasure, to accord to Thomas B. McBride, of Philadelphia, the credit of having within the last few months devised an apparatus somewhat similar in principle to the one just described. A description of his apparatus will be found in the *MEDICAL AND SURGICAL REPORTER* for June 4, 1887. He writes me that he has, since

that publication, added the hinge, thereby lessening the length of the apparatus when not in use.

In conclusion, I will add that I have found the apparatus serviceable in all operations in which the lithotomy position is indicated, and particularly when operating for slight lacerations of the cervix where no anæsthetic was administered.

THE PRESIDENT asked Dr. Haven if the apparatus answered as well when the patient was under an anæsthetic.

DR. JOSEPH HAVEN: It answers better. I have used the apparatus a number of times with an anæsthetic, and several other physicians have used it. The patient is liable to come out of ether before the operation is finished, and with this apparatus she cannot do herself any harm during the operation.

DR. TOBIAS asked Dr. Haven in how many cases of laceration of the cervix he had tried the apparatus, and if the patient ever raised any objection to its use.

DR. HAVEN: Probably twelve or fifteen. No objection has been made to the apparatus, except in one case. But you will find that some patients object to any instrument. This patient asked me what it was, and when I explained that it was not an instrument of torture, she readily consented to its use. However, where an anæsthetic is to be given, I do not usually put it on until the patients are anæsthetized, and they do not see the instrument at all. It can be put on in less than one minute, and taken off in the same time. I very often use it in dressing wounds around the uterus, packing the vagina after opening a pelvic abscess, where I do not care to employ an assistant to hold the patient in the lithotomy position, or for slight operations on the rectum,—anything that would not require an anæsthetic.

—THE RUSH MONUMENT.—The State Medical Society of California at the recent session in San Francisco, unanimously adopted resolutions heartily approving the project of erecting a statue of "the immortal Benjamin Rush," in the city of Washington, and requesting the various medical journals to call upon every physician in the State to contribute the very modest sum of one dollar each to which the subscription has been limited.

—M. Chevreul will be 101 years old in August. His family and friends intend to celebrate his birthday, but the old chemist desires that no public demonstration be made on the occasion.

EDITORIAL DEPARTMENT.

PERISCOPE.

Severe Injury in a Woman Pregnant with Twins.—Expulsion of one Fœtus at the End of Eighty Days.—Retention of the Other up to Full Term.

Dr. E. Sirois, in the July number of *L'Union Médicale du Canada*, reports the following case :

On the first of December last, I was called to Mrs. H., who, I was told, had just had a fall. The patient, who weighed about one hundred and ninety pounds, had fallen, head-first, from a wall ten or twelve feet high. When I saw her, a half-hour after the accident, she was bleeding at the nose and ears, and was delirious. In spite of all I could do, her condition grew worse, to such a degree that five hours later she was in profound coma, with complete insensibility, widely dilated pupils, paralysis of the bladder and rectum, labored respiration (from six to twelve in the minute); pulse thready, and very irregular, varying between one hundred and twenty and one hundred and sixty. I consulted with a brother practitioner, who believed that there was a severe lesion of the base of the brain, and declared that the woman would die. For my own part I had no idea but that she would die before morning. I, however, remained with her, pretending to be doing something, so as not to take away too suddenly what little hope remained to the sorrowful family. Toward the latter part of the night, eleven hours after the accident, the respiration became gradually more regular and less labored, while the pulse became stronger and remained at one hundred and thirty. At nine o'clock on the following morning (December 2) fourteen hours after the accident, she had completely recovered consciousness, but complained of intolerable pain in the head, neck and shoulders. I knew the patient was pregnant, but pains, which were present, were of a nature to distract attention from the uterus. On the tenth day she lost by the vagina about two ounces of blood, which were followed by the expulsion of a fœtus *without labor pains*. Then all her troubles disappeared. There was no more headache, no more pains in the limbs. Two days afterwards my patient was engaged in her ordinary duties. The ovum, which was expelled, was intact. I opened it myself and established the presence of a very well formed embryo about seventy or eighty days old. On the sixteenth of May, that is to say,

less than seven months after the accident, Mrs. H. gave birth to a boy at term, weighing ten and one half pounds. She had, therefore, at the time of the accident, lost the half of a double conception.

The Relation of Uric Acid Excretion to Headache.

Headache is a disorder to which physicians are perhaps even more prone than the majority of their patients, and one would suppose that they would be particularly interested in the subject. But it is not often that the matter receives very exhaustive treatment in medical writings, and the monograph of Dr. W. H. Day, published some years ago, is perhaps the latest which has appeared on the subject.

At a recent meeting of the Royal Medical and Chirurgical Society of London, Dr. Alexander Haig presented a paper on headache, which contained some interesting suggestions. Considering that headache has frequently some clinical relationship to gout, the author has examined the urine with a view of deciding the question. A headache was experimentally produced on himself by adopting a diet of meat and cheese. The urine excreted during the headache was kept separate from that excreted before and after. There appeared to be retention of uric acid before the headache, excessive excretion during the headache, and diminished excretion after the headache. Taking the three periods, however, and comparing the urines, there was no absolute excess of uric acid passed. The temporary excess during the headache was balanced by the diminution before and after. There was little change in the amount of urea passed during a headache, but the relation of the uric acid to the urea was greatly altered. When, after excessive exercise, there was a large excretion of urea and uric acid (though in their normal relation), headache was not far off; and if from any cause the uric-acid excretion fluctuated, headache would be present during its excess and absent during its diminution.

This fluctuation in the uric acid excreted did not affect the urea, and it was merely temporary and transient; it has also been proved that urates may accumulate while the kidneys are quite sound. Dr. Haig suggested that diminished alkalescence of the blood best explained all this. Gout, he thought, might consist in a diminished power of forming ammonia to neutralize

acids, resulting in a permanent diminution of the alkalescence of the blood. A dose of acid, either from without or formed internally, might cause temporary retention of uric acid and so lead to headache.

Probably, however, as the author suggested, retention does not explain everything, as in his case the excess during the headache appeared to exceed the previous retention. There may be temporary excessive formation as well; hence the good effect of sodium salicylate, which lessens the formation of uric acid. The beneficial effects on this form of headache of a good meal, vegetarian diet, and alkalies were severally due to a temporary increase in the alkalescence of the blood.

On the Treatment of Lupus by Scraping.

Mr. Rushton Parker, Professor of Surgery in University College, Liverpool, writes, in the *British Medical Journal*:

The practice of scraping with a sharp spoon, or other convenient instrument too blunt to cut healthy tissues easily, has proved of such conspicuous advantage in the treatment of unhealthy granulating surfaces as to be hardly capable of exaggeration, though its general utility is too well-known to need much advocacy. Though cases of lupus vulgaris and all forms of strumous or otherwise indolent flabby ulcer yield better, in my opinion, to scraping than to any other treatment, their alternative curability by caustics, whether incandescent or chemical, is perfectly known. Various methods lead to healing in cases of lupus; the principle that underlies is removal of the morbid stuff from the tissues it keeps unhealed, whether this be by dissection, scraping, or burning *in situ*.

The worst specimens of ulcerating lupus readily heal after thorough scraping once or oftener; also the less evident cases of lupus erythematosus, and others of dry scabby lupus that are neither erythematous nor serpiginous, but none the less ulcerative, after an indolent fashion; and other cases, again, that are warty in some parts, pustular in others, and are not at first conspicuously recognizable as forms of lupus at all. Although lupus most commonly affects the young, and women more than men, we meet it at any age over ten, in both sexes; and when, as I have seen, it affects the hands, arms and neck of a man aged 58 in such an untypical form as scattered pustules and warty patches, the disease is apt to be neglected, overlooked, or unrecognized, on account of its apparent slightness. Such a case, twelve months un-

healed, I treated by scraping with a blunt knife, repeated once or twice a week as fresh tubercles appeared, finally healing in three weeks.

The instruments I have resorted to, on the spur of the moment, for scraping lupus on a small scale, are a straight shoemaker's awl, and even a pointed wooden lucifer match, the point of a tooth-elevator, a gum-lancet, or a broad eye-spud, suitably blunted, so as not to cut healthy tissues. This last I have used more frequently than anything else for the small pustular, pearly or miliary nodules one meets with as recurrences in cases requiring repeated operation, and as first manifestations in some of the more obscure varieties, and for lupus erythematous, of which I have had a conspicuous example in hand for the last two years. In that period scraping has been done seventeen times, at intervals of from twelve days to three months, in a woman aged 35. The disease has lasted fourteen years, during the last ten of which I have frequently seen her. Some years ago her cheeks and nose were bright red, under a whole cuticle, and raised. She had been several times apparently nearly cured, after repeated cauterizations with a fine heated point, but never got quite well. A very steady improvement has taken place under the scraping, which has sometimes to be applied to minute miliary nodules no bigger than a millet-seed. For hæmostatic purposes I use a wire ring, set at an obtuse angle, mounted in a handle, and pressed firmly round the spot operated on; and, as soon as the scraping is done, solid nitrate of silver, rubbed into the raw surface. This effectually arrests or prevents bleeding, and secures for a few days an aseptic scab. In more extensive cases, requiring the sharp spoon, nitrate of silver is similarly applied, followed by a dressing of boracic lint or sublimated gauze, wet, under waterproof tissue.

A year or two ago I used liquor calcis bisulphitis, a lotion that has been much praised for lupus and for the sores left after excision of rodent ulcer. But I have not been able to find in it anything more than a convenient antiseptic, neither better nor worse than others in everyday use. I gave it a good trial also as a subcuticular injection into the lupus growth last referred to, before resorting to scraping; but it proved quite useless. What I claim for scraping is its thorough removal of morbid granulations, without waste by destruction of adjacent healthy structures, and the accuracy with which it can be done when the part is rendered bloodless by ring pressure.

The Fluorides of Ammonium and Iron in Hypertrophy of the Spleen.

In the *Practitioner* for June, 1887, Dr. John Lucas presents a number of cases treated as above indicated. The time required to effect a reduction of the hypertrophied spleen to its normal size was about three months. He writes as follows regarding the details of treatment:

I prefer the salts to the acid, because they are less unstable. The ammonium fluoride (NH_4F) is prepared by saturating a solution of hydrofluoric acid (HF) with ammonia (NH_3), and allowing the mixture to evaporate over quick-lime. The fluoride of ammonium crystallizes in hexagonal prisms, dissolving readily in water, and the solution is colorless; but it acts on glass (for chemical reasons which I need not enter into here), going through it and escaping. To prevent this escape the expedient of coating the inside of the bottle with wax, so as to prevent the unstable compound in solution from coming in contact with glass, has to be resorted to; or the solution may be kept in india-rubber tubes or gutta percha bottles. I adopted the first-named plan, and did not cause more of the solution to be made than was actually wanted for use. The strength of the solution employed by me was four grains to the ounce. Of this *liquor ammonii fluoridi* I began with 5-minim doses, diluted in an ounce of water and administered thrice a day after meals, and the dose after a day or two may be increased to 8 minims, then to 10, 12, 15, 18, 20, and so on at intervals of a few days, the increase being effected gradually and cautiously; the great point to attend to is to insure the taking of this medicine after food, as otherwise gastric and intestinal irritation will be set up, while with this precaution it will be found to be fairly well tolerated in the majority of cases.

Remarks.—Certain physiological effects, more or less common to all the cases, were observed. Briefly, there was a marked influence on the blood-pressure, which had a downward tendency at first; the pulse fluctuated and the number of beats was lessened. In this respect my experience was quite in accord with that of Dr. Coates. It was also found that the drug possessed antipyretic properties when the temperature ranged above the normal point, and it prevented attacks of ague, thus proving it to be an anti-periodic. Dr. Coates writes that he did not notice this action. In all the cases it produced nausea at first, though gradually a sort of tolerance appeared to have been

established, and the drug could be borne in much larger doses. It produces some intestinal irritation, probably acting more on the duodenum, and giving rise to some diarrhœa. I am not sure that it has any action as a hepatic stimulant. The appetite after a time improves under its use. Almost all the patients complained of a pricking or twisting pain or uneasiness in the spleen itself, the original pain being sometimes aggravated. When given carefully and after meals, which should be the invariable rule, it is better borne and does not produce nausea and purging to the same extent. It certainly seems to excel any other method of treatment with which we are acquainted. It is a new remedy in this connection, and I would solicit trial and report on it by physicians in this country as well as in India, and not only in the treatment of splenic hypertrophy, but also in that of goitre. Although I began with small (5-minim) doses, I should be disposed to start with 20 or even 30 minims diluted in an ounce or two of water and administered always after a meal. The combination of iron with hydrofluoric acid, I am inclined to think, would prove more valuable on account of the hæmatinic properties of the former, and because as an adjunct it would exercise its astringent and tonic influence on the mucous lining of the stomach and intestines, and thus in a great measure tend to counteract the unpleasant effects complained of, and perhaps also to augment the evident specific action of the spleen. The fluoride of quinine can easily be prepared, and so also can the triple fluoride of iron, quinine, and ammonium.

Oxygen Baths in Febrile Conditions.

A Spanish observer, Dr. F. Valenzuela, starting from M. Paul Bert's results showing the destructive action exerted by oxygen of high tension on vegetable and micro-organic life, has recently made a number of interesting observations on the power of an atmosphere of pure oxygen to affect the febrile state. He found that the temperature of healthy rabbits, after being kept for an hour in pure oxygen, at pressures of from 760 millimètres to 1,520 millimètres, underwent a marked diminution, amounting in the last case to as much as 11°F . Again, rabbits into which septic matter had been injected so as to induce pyrexia, suffered a decided diminution of the fever by immersion for one or two hours in an atmosphere of pure oxygen. In one experiment, where two rabbits were similarly injected, one, which was twice bathed in oxygen at a tension seven times as high as

that which it has in the atmosphere recovered, while the other, which was left untreated, died on the third day. Several observations were also made on hospital patients. Two cases of acute pneumonia, treated with oxygen "baths" at a pressure of 960 millimètres, ran a peculiarly rapid and favorable course. In a phthisical case with a temperature of 103.6° F. an oxygen "bath" brought the thermometer down to 101.3° . The next evening the temperature rose as before, and was again reduced in the same manner; slight hæmoptysis, however, was caused by the "bath." The next day there was no rise of temperature. After two days, a third "bath" was given, and from that time the febrile condition appeared to improve, for though the temperature sometimes rose above normal, the pyrexia was never so pronounced as it had been. From a second case of the same kind reported, there would seem to be a decided danger of these oxygen "baths" producing hæmoptysis. On the temperature, however, they appear to exert a very beneficial effect.—*Brit. Med. Journal.*

A Case of Intestinal Tuberculosis which had been Cured.

Under this caption, the *Allg. med. Central-Zeitung*, for June 11th, has the following interesting particulars: Dr. Hartwig made in December, 1885, a preliminary incision into a woman with marked ascites, in whom a positive diagnosis was not possible. There were about three-quarters of a bucketful of a clear pale liquid evacuated. The genital organs were unaltered, but the whole peritoneum was strewed with tubercles. Convalescence was without reaction. In a dissected piece of the peritoneum tubercle bacilli could be recognized with certainty.

One year after the operation, the patient had a blooming appearance and felt well. Ascites had not reappeared. Physical signs of pulmonary disease were not recognized.

A Brilliant Clinical Diagnosis.

In the *Centrallblatt f. d. med. Wissensch.*, for June 11th, there is the following account of a case of acute endocarditis occurring in the practice of Spronck. He accurately describes the case, that of a patient twenty years old, which is especially interesting from its complications. With the endocarditis was insufficiency of the mitral, and subsequently an embolic aneurism of the superior mesenteric and right femoral developed. The autopsy of the case, which came to its

fatal termination through pulmonary phthisis, established the clinical diagnosis completely. The anatomical diagnosis runs as follows: tuberculosis of the lungs; acute vegetative endocarditis of the mitral valve, with insufficiency, and dilatation of the heart; arterial aneurism of the superior mesenteric and right femoral; embolism of the artery of the fissure of Sylvius of the left side; multiple infarcts of the spleen and kidneys. During life the difficult diagnosis of aneurism of the superior mesenteric could be established through a pulsating tumor in the epigastrium of the size of a hen's egg. The differential diagnosis (of epigastric pulsation, tumor pressing upon the aorta, aortic aneurism, aneurism of the coeliac axis) is satisfactorily cleared up.

Heat-Stroke at Assouan in 1886.

Under this heading Surgeon G. Douglas Hunter gives the following interesting accounts of the symptoms and treatment of thermic fever as observed in the tropics:

The usual type was as follows:—A man was carried in with flushed face, hot, dry, burning skin; if conscious, complaining of intense pain in the head; generally unconscious, pulse feeble, breathing shallow and labored; at times comatose, with stertorous breathing, in others violent convulsions relapsing into coma. The initial temperature generally varied from 104° to 107° ; you could not depend on the strict accuracy of the clinical thermometer, owing to the high temperature of the external air, but the bodily temperature was always very high.

The cases occurring in patients in hospital presented similar symptoms, but were generally more insidious. Several cases exhibited a kind of premonitory stage, the patient being admitted to hospital with slight febrile disturbance, and after a day or two developed the disease in its full intensity.

In cases of enteric fever in which it occurred, it was either speedily fatal or seriously complicated the disease, the symptoms being high temperature, hot, dry, and burning skin, flushed face, and great prostration, which, if yielding to treatment, left the patient very weak and less fit to cope with the original disease.

In severe cases, in which the patient became comatose early, he usually died in a few hours without rallying. One or two cases rallied and then relapsed into coma. Case 6 was the longest case that terminated fatally. If the attack yielded to treatment the patient was left very prostrate, feverish, furred with tongue, headache, etc., which passed

off generally in a few days, and left him convalescent but weak and debilitated.

Most of the cases which recovered were considerably debilitated, and required change of climate; I am unaware if they suffered from brain mischief later on.

Treatment must be immediate and thorough. The patient should be stripped and laid in the coolest place possible—in the shade outside is best—and cold water dashed on the head and spine; this should be maintained; a large enema administered and the lower bowel well emptied. If the patient regains consciousness, he may then be placed on his bed (if the temperature remains high) in a wet pack, and ice kept to his head. Five grains of calomel may then be administered, and diaphoretics given frequently. To promote free action of the skin and maintain the action of the bowels is very needful. If a relapse threatens, douching should be at once resorted to. If there are no signs of rallying, use sinapisms to the heart, frequent douching, ice to head and spine, friction of the limbs; if the pulse is failing, brandy at frequent intervals in small doses and brandy enemata. If respiration is failing, artificial respiration should be employed and well kept up. On no account give up every attempt till life is quite extinct. On no account bleed the patient. The after treatment is to maintain free action of the skin and bowels—tonics and change of air to a temperate climate.

The essence of treatment is to reduce the bodily temperature as speedily as possible, and the surest way to do this is the application of cold water and ice; this should be maintained, and the least relapse dealt vigorously with in the same way. Immediate action of the bowels by enemata is very necessary, and an emetic is beneficial in suitable cases.—*British Medical Journal*, July 9, 1887.

The Relation of Erysipelas to Syphilis.

In the *Centrallblatt f. d., med. Wissensch.*, for June 18th, there is an abstract from a paper by Schuster under the above heading, which says: In a woman suffering from syphilis of the nasal passages a severe attack of erysipelas developed itself from a small wound at the border of the nostril from which the patient died. In another case there arose likewise a very grave repeated erysipelas in a man, during specific treatment for a latent state of syphilis; this did not hinder the later outbreak of the syphilitic ulcer.

In a third patient, syphilis of the nasal passages formed directly the point of origin of a many-times-repeated erysipelas, and with the cure of the first also disappeared. Upon these experiences, he considers erysipelas a serious complication of syphilis, and suspects a specific and permanently curative action of the former upon the latter.

Are Tumors Caused by Bacteria?

In *Schmidt's Jahrbücher* for June 15, 1887, occurs the following: M. M. Galippe et Landouzy, in *Gaz. des Hôp.*, 24 p. 158, 1887, say they have transferred small pieces of tissue from two uterine myomas, immediately after the operation, into different culture fluids, and found in two days pure masses of micro-organisms in the fluids. Sometimes they were arranged in large heaps or in long chains of diplococci, then narrower streptococci, finally bacilli, partly isolated, partly as long threads. In both tumors these same micro-organisms were to be found. The authors could also recognize micro-organisms in the contents of two ovarian cysts.

From their investigations the authors think they can draw the conclusion that solid, as well as cystic tumors in animals arise from a wandering in of lower organisms, just as excrescences are produced upon plants.

Excessive Salivation in Pregnancy.

With reference to this subject, Justus Schramm, in the *Allgemein. med. Central-Zeitung*, has reported the following case: A woman, who was seven months pregnant, poured out within twenty-four hours twelve hundred cc. of saliva; nausea, vomiting and great weakness were present, and the gums very much swollen. After all other means, such as iodide of potash, atropine, duboisin and galvanization of the sympathetic, etc., etc., were tried in vain, bromide of potash proved extraordinarily successful. She was given a tablespoonful three times a day of a twelve per cent. solution of bromide of potash.

The Action of Belladonna and Opium in Diabetes.

Villeman (*Comptes rend.*, No. 7, 1887), writes as follows: In a young artilleryman, with a high degree of diabetes, who in spite of appropriate diet passed twelve to fourteen litres of urine containing about five per cent. of sugar, a combination of belladonna and opium caused a disappearance of sugar, and of all the symptoms of the disease. Improvement continued as long as the treatment was used, although other measures had given no result.

The Intraperitoneal Injection of Koch's Comma bacilli in Guinea Pigs.

Upon this subject, Vincenzi, in the *Centralblatt für die med. Wissensch.*, of June 18th, reports as follows: In opposition to the lately published researches of Huppe, who had seen the death of the animals experimented on, invariably follow the intraperitoneal injection of one centimetre up to a drop of cholera bacilli, that, in ten guinea pigs in whom under avoidance of every injury of the contents of the peritoneal cavity, ten to twenty drops of a second day's culture of cholera bacilli were carried into the belly, no disturbance of health could be obtained. Vincenzi supposes that cholera bacilli are re-absorbed in the belly, just as an injection of indigo solution in the lymph stream, and then deposited in the blood.

Gravel as a Purgative in Habitual Constipation.

In the *Allgemeine medicin. Central-Zeitung*, for June 22d, Dr Von Kacorowski, of Posen, recommends gravel in pieces the size of millet or hemp seeds, ten grammes to the dose, or a teaspoonful morning and evening, as a purgative: "1st. In habitual constipation. 2d. In chronic catarrh of the alimentary canal, from the mouth to the large intestine. 3d. In chronic heart and lung diseases of anæmic persons who would be weakened by a very active purgative. But it is especially advantageous and to be preferred in those cases of constipation which depend upon a spasmodic constriction of the circular muscular fibres of the anus, which are met with particularly in young persons with increased excitability of the nervous system, which exists with an organic or functional state of excitement of the genital organs, but especially in association with masturbation."

We cannot but commend the child-like obedience of German patients.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT LITERATURE.

—Lea Brothers & Co., Philadelphia, have in press for early publication the third and final volume of the 'American System of Dentistry,' 'A Text-Book of Materia Medica and Therapeutics,' by Dr. Robert T. Edes; and 'A treatise on Human Physiology,' by Henry C. Chapman, M.D., professor of physiology in the Jefferson Medical College, of Philadelphia. For the same press, Dr. Roberts Bartholow, professor of materia medica and therapeutics in the Jefferson

Medical College, is preparing a work entitled 'New Remedies of Indigenous Source, their Physiological Actions and Therapeutical Uses,' which will make an octavo volume of about 300 pages.

BOOK REVIEWS.

The Relation of the Nervous System to Hæmophilia, Malarial Hæmaturia, etc. (Second paper,) C. H. Hughes, M. D., St. Louis. (Reprint from *The Alienist and Neurologist*, July, 1887.)

The author attempts to prove that hæmophilia is an "hereditary or congenital neuropathic affection of the sympathetic system." Malarial hæmaturia, purpura hemorrhagica and certain mythemias are due to "the lost vaso-motor control that allows arterial dilatations and permits of the fatal pressure of passive congestions and sanguinuric execution."

A Manual of Treatment by Massage and Methodical Muscle Exercise. By Joseph Schreiber, M.D., member of K. K. Gesellschaft der Aerzte, in Vienna, etc. Translated with the author's permission by Walter Mendelson, M.D., of New York. pp. 285. Philadelphia, 1887. Lea Brothers & Co.

It is very evident that at the present day there exists a stronger tendency than ever to employ external medication, not at the expense of, or with a purpose to supplant internal therapeutics; but merely on account of a better knowledge of the physiological and pathological conditions to which such treatment is applicable. The volume before us, which is well illustrated, is divided into five interesting chapters, the first of which is devoted to a definition of massage, and in it it is held that the hand is superior to machinery, and that every physician by self-teaching, can acquire the art of mechano-therapy. Chapter second describes the physiological effects of massage—(1) Primary—removal of lymph, exudations, extravasations, etc.; (2) Secondary—increasing the circulation and stimulating the muscular and nervous system. In chapter third the methods of massage, such as pressing, tapping, pinching, squeezing, rubbing, and stroking are described; chapter four is devoted to an exposition of the physiological effects of calisthenics, and of the Swedish movement cure; and chapter five treats of the diseases to which mechano-therapy is suited. It is a book which, if it is well studied and its directions followed, will be a great gain to both physician and to many of his patients.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, -	6.00
Physician's Daily Pocket Record, -	1.50
Reporter and Pocket Record, -	6.25
Reporter, Compendium and Pocket Record.	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

DRS. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets,
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER will be published in each number. The edition for this week is 5,000 copies.

SPECIAL NOTICE TO SUBSCRIBERS.

Subscribers to the MEDICAL AND SURGICAL REPORTER, who have remitted payments to the former editor, and who do not find upon the wrapper of their journal a correct statement of the time up to which they have paid, are requested to notify the present publishers as soon as convenient.

DEVIATIONS OF THE SEPTUM NARIUM.

A number of theories have been advanced to explain the cause of deviations of the septum of the nose which sometimes give so much trouble to those who have them. Many authorities believe they are largely due to traumatism. Others believe that they are due to defects of development, while some go so far as to say that they are always due to such defects, and that these defects implicate the whole of the superior maxilla.

It is likely that the truth is between these two beliefs. Most deviations are probably due to defects of development either inherited or acquired. No doubt a fracture of the septum may occur and leave a permanent deformity behind it. But many occur without any traumatism, and in others a traumatism is the cause of the defective development.

In any case a deformity results which is often a source of annoyance, and sometimes of actual danger. To correct it various operations have been devised: exsection of a portion of the septum, cutting off of the protruding angle, and forcible straightening of the bone.

The latter operation is simple and safe. To do it a pair of strong, straight forceps are introduced—one blade in each nostril—and the septum is forced into a correct position. For this purpose, a pair of straight bone-forceps, the blades of which have been wrapped with adhesive plaster, will do very well. After this a smooth, round needle is thrust up alongside the septum, under the mucous membrane and even into the septum itself, to act as a splint. This is left in place for eight or ten days, and then removed. Afterwards the correct position is to be maintained by the use of little cones made of hard rubber or ivory.

The results of this little operation have proved very satisfactory to those who have performed it; and it would seem to have decided advantages over any cutting operation.

THE DIFFICULTIES AND DESERTS OF MEDICAL JOURNALISM.

It is almost pathetic to observe the way in which the following item is going the rounds of the medical journals:—

“The following from the *American Medical Journal* may be of interest to the readers of regular publications: ‘A newspaper in Illinois recently brought suit against forty-three men who would not pay their subscriptions, and obtained judgment in each for the full amount of the claim. Of these, twenty-eight men made affidavit that they owned no more property than the law allowed them, thus preventing attachments. Then they, under the decision of the Supreme Court, were arrested for petty larceny, and bound over in the sum of \$300 each. All but six gave bonds, while six went to jail. The postal law makes it larceny to take a newspaper and refuse to pay for it.’”

In the same connection we have recently noted an appeal from a very able Kansas City

contemporary to its subscribers, in which the statement is made that among "many hundreds" upon its books, there are only *two hundred and twenty* marked "paid to January, 1888."

It is unquestionably a shame that some physicians will not pay for the journals they take. But this is partly the fault of the journals themselves, which often push and crowd the doctor to subscribe, entice him on with special attractions which are not continued, let him run up a bill which gets big before he knows it, and then come down on him for payment.

The fact is there are almost too many medical journals. Those which are successful in every sense have their prosperity diminished by the sharp competition and underbidding of others for which there is but little *raison d'être*, and the latter struggle along, with few subscribers, few writers and no profits; doing harm to other journals and no good to themselves.

To any journal which really has a mission, struggle and hardships are the necessary preparation for success. To any journal published solely to make money, to gratify vanity, or to bolster up a commercial interest these experiences are apt to be the foretastes of failure.

We extend our hearty sympathy to every worthy struggler in the field, and commend to all the unflinching determination of the REPORTER to be such a good medical journal that thousands of medical men shall feel that they cannot do without it, and that they will pay for it—as they now do.

ANTIPIRYN AND ANTIFEBRIN AS ANALGESICS.

M. Germain Sée, in a paper read before the French Academy of Sciences, reports remarkable results from the use of antipyrin as an analgesic. He has used it in subacute rheumatism, and acute gout both primary and secondary to chronic gout with chalky deposits. Antipyrin, in doses of a drachm to a drachm and a half, removed both pain and swelling in from two to four days, without any bad effect upon heart or kidneys. Moreover, he has used it with particular suc-

cess in neuralgia and migraine, in sciatica, diabetic neuritis, zona, and locomotor ataxia. Confirmation of these good results is beginning to come in from other competent observers. More recently, Dr. H. M. Fisher reports a case in which he obtained a very happy result from the use of antifebrine in spinal syphilis. A noteworthy fact in these cases is that the pain does not always recur, and when it does is not so severe.

In recording the similar results produced by antipyrin and antifebrin, one is forcibly reminded of the studies of Blake, in which he has shown that, with some exceptions, metals which form isomorphous salts have the same physiological action, and that the physiological power increases with the atomic weight of the members of these isomorphous groups. Most of the new antipyretics (kairin antipyrin, thallin, antifebrine, antithermin, etc.) are isomorphous, crystallizing in rhombic prisms. Again, Lauder Brunton and Cash have found that in most of the cases in which a union is made between the amidogen and the methyl radicles in the alkaloids, there is a paralyzing action, and this action is said to be greater with than without the methyl radicle in connection with the amidogen in the alkaloid.

These new drugs are synthetic compounds. It would almost seem, therefore, that the science of chemistry is rapidly approaching such a state of perfection that it may soon be able to produce any drug as soon as the therapist had indicated what physiological action was desired.

MODERN METHODS IN HYPODERMIC MEDICATION.

Some weeks ago a correspondent inquired about the recent developments in the methods of hypodermic medication. We take pleasure in presenting in this number a very full list of the drugs thus employed, with doses and a statement as to strength of solution which has in each case been found most advantageous. One of the most important functions of a good journal is to give full, clear, and reliable replies to the queries of its readers. Our readers will always find the REPORTER prompt to respond to calls of this nature.

NOTES AND COMMENTS.

HYPODERMIC MEDICATION.

ADAPTED FROM EWALD'S HANDBUCH DER
ARZNEIVERORDNUNGSLEHRE.

The method of hypodermatic or subcutaneous injection was introduced into therapeutics in 1855, by Alexander Wood. In the meantime it has been so universally and heartily adopted by the profession of all countries, that it may now be considered as one of the most important advances of modern times in the department of practical medicine.

The process consists in the production of a local or systemic effect by the introduction into the subcutaneous connective tissue, of accurately graduated doses of the medication chosen. For this purpose there is used a small glass syringe provided with a lance-like hollow silver needle. Upon the piston (or cylinder) of the syringe there is a graduated scale, enabling one to estimate the exact amount of liquid at any time below the piston-head. The connections of the piston and cylinder are usually made of silver, though more recently vulcanized rubber has been used.

The first step is to fill the syringe with the amount of the solution it is desired to introduce into the organism. The skin of the spot is then rendered tense* by the thumb and forefinger of the left hand, whilst with the right, the needle of the syringe (held as a penholder), is pushed with a short, quick thrust, five to ten millimetres (one-fifth to two-fifths of an inch) beneath the surface, much in the same manner that one would puncture an abscess. After withdrawing the needle from the skin, the spot may be covered by a bit of adhesive plaster if thought desirable, though the escape of blood is so unimportant that this may be neglected. Many amateurs, and even more expert operators, make the mistake of entering the needle too slowly and not deeply enough. The operation, essentially trifling, is thus made more painful, and abscess is thereby rendered more probable by the different drugs used. Especial attention is to be directed that the canula be kept scrupulously clean. Our rule is, preceding an injection, to cleanse the

canula and needle by repeatedly drawing through it hot carbolized water.

The accurate dosage of the liquid to be injected is highly important, and for this purpose we must know the capacity of our syringe. Within certain limits, different syringes vary in this respect, and it therefore becomes necessary for every physician to determine exactly the capacity of the one he uses. At the present time most foreign instruments are made to hold one cubic centimetre, or one gramme [= 16.231 minims of water, or 15.434 grains Troy] of distilled water, the piston being graduated into fifty equal parts. One of these parts, therefore, corresponds to 0.02 ccm. [three-tenths of a minim or grain] of the liquid. The instruments generally used in the United States contain 25 minims, the scale upon the piston showing a division into 25 equal parts.

Subcutaneous injections are indicated in the following circumstances: In order by absorption to produce a prompt effect either locally or upon the physiological centers. In this way they are used especially to control spastic, neuralgic, and painful derangements generally; also insomnia, mania and delirium; latterly, also, they have been used as excitants; they are, moreover, of service in hemorrhages, intoxications (notably by curare in strychnine poisoning), intermittents, in amblyopia and amaurosis, aneurism, internal hemorrhages, uterine diseases, (especially in myoma and fibroma), parenchymatous ulcers, etc., etc.

When it is desired to produce a local effect, as, for example, the relief of neuralgia, the place of puncture is chosen as near as possible to the painful tissue. In neuralgia a point may be found that reacts painfully to pressure, and this *point douloureux* is the best place to insert the needle. For systemic effects the location is unimportant. If repeated injections are to be made, different spots are to be chosen.

The drugs used are numerous. When the drug is in a sufficiently concentrated form, and soluble in water, glycerine or dilute alcohol, and if, moreover, it be not too severe a local irritant, it may be used in the manner proposed. There is an increasing number of such agents being constantly introduced. The most important now used in this way are the following: *

* If the points chosen be over superficially situated bone, as, e. g., the temple, the skin must be pinched up instead of made tense, by the left hand, and the needle thrust between the skin and the periosteum. If the place be in the neighborhood of important nerves, arteries, veins, etc., these must be carefully avoided.

* The approximate equivalents of the metric system are given below in Troy measures or minims. This accounts for the peculiar fractions sometimes resulting. For small amounts the uniform measure of minims is used, practically equivalent to the grain in aqueous solutions.

ACIDUM BENZOICUM.—One part dissolved in twelve of alcohol; a whole syringe-ful, and, if necessary, others at short intervals; as an excitant, and in uremia. Solution and syringe should be slightly warmed before injecting. (*Rhode*).

ACIDUM CARBOLICUM.—Of a one to two per cent. aqueous solution, inject 15 to 30 minims, *i. e.*, gr. $\frac{1}{8}$ — $\frac{1}{4}$ of the acid. (Recommended first by *Hueter*.)

ACONITUM.—Dissolve gr. iss in aquæ $\mathfrak{z}$ iss, and inject from 3 to 6 minims, *i. e.*, gr. $\frac{3}{8}$ to $\frac{1}{2}$ aconitin.

ETHER, ACETIC ETHER, AND SPIRIT OF ETHER.—As an excitant in extreme collapse, one or more syringe-fuls.

APOMORPHINÆ HYDROCHLORAS.—Gr. iss dissolved in $\mathfrak{z}$ iss of water; of this inject 8 to 16 minims, *i. e.*, gr. $\frac{1}{3}$ — $\frac{1}{2}$ of apomorphine as an emetic dose.

ATROPINÆ SULPHAS.—Dissolve gr. $\frac{1}{2}$ in $\mathfrak{z}$ iss of water and inject $\mathfrak{m}$ iij— $\mathfrak{m}$ viij, or gr. $\frac{1}{16}$ to $\frac{1}{8}$ at a dose. Of *atropinum valerianicum*, the same. The combination of atropine and morphine in the proportion of one part of the first to one-tenth of the last (or less), is recommended by Nussbaum and Fraignaud. The toxic effects of the individual components are said to be obviated whilst the combined action is unaffected. Gelatine discs of morphine and atropine are to be had.*

CAMPHORA.—A syringe-ful of a one in twelve alcoholic solution, as excitant.

QUININÆ HYDROCHLORAS (THE CARBAMIDE.)—One or two parts to ten of water are said to produce no irritant effect.

QUININÆ SULPHAS AND HYDROCHLORAS.—One part to ten of water (adding a few drops of sulphuric acid), or one to six of glycerine (without the acid); inject $\mathfrak{m}$ v to $\mathfrak{m}$ xv or, gr. $\frac{1}{3}$ to jss, as a dose.

These injections frequently produce symptoms of local irritation, sharp pains, abscesses, etc. According to Köbner, quininæ, hydrochlor. gr. ii–iv with water or glycerine, $\mathfrak{a}\mathfrak{a}$ gr. viiss, (*i. e.*, in the proportion of one to four of the menstruum) yields, with warmth, a clear solution which, injected when tepid, causes no irritation.

QUININÆ BISULPHAS.—Soluble in glycerine one to three.

QUININÆ HYDROBROMAS.—Said to combine the sedative effects of bromine with the action of quinine (Gubler). It is

soluble (with heat) in about 15 parts of water, or 4 of glycerine. Gr. xv in $\mathfrak{z}$ iss of glycerine, and $\mathfrak{z}$ i of water yield gr. iss of the drug to $\mathfrak{m}$ xv. Used by Soulez in intermittents, in doses of gr. viiss–gr. xv. Other salts, as quinin. ferro-citricum, bitartaricum, valerianicum, etc., are recommended, but are less important than the above.

HYDRATE OF CHLORAL.—Five parts to ten of water; one to three syringe-fuls, containing gr. viiss to gr. xxxvii of the hydrate to the dose. Little suitable.

COCAINÆ HYDROCHLORAS.—One to two parts, to ten of water; as a local anæsthetic. Especially recommended by Mandelbaum in combination with quicksilver, in the subcutaneous treatment of syphilis.

COFFEINA.—Dissolve gr. xv in alcohol and water, each, gr. xxxvii and inject $\mathfrak{m}$ x— $\mathfrak{m}$ xv or more, as a dose; *i. e.*, gr. $\frac{1}{8}$ —gr. $\frac{1}{2}$ of caffèin.

CONIUM.—Gr. iss in alcohol, dil. et aquæ $\mathfrak{a}\mathfrak{a}$ $\mathfrak{z}$ iv; inject $\mathfrak{m}$ ij— $\mathfrak{m}$ iij=conium. gr. $\frac{1}{8}$ —gr. $\frac{1}{2}$.

CURARE OR WOORARA.—A very unequal preparation of differing solubility: gr. iss in $\mathfrak{z}$ iss of water; inject $\mathfrak{m}$ iij— $\mathfrak{m}$ viij, containing of curare gr. $\frac{1}{2}$ —gr. $\frac{1}{8}$. The dose is not accurately to be laid down, and must be determined by the efficacy of the drug previously proved by trial upon animals, and by the existing circumstances of the case. Offen- burg injected in hydrophobia three grains in $4\frac{1}{2}$ hours, and Penzoldt $5\frac{1}{4}$ grains in $10\frac{1}{4}$ hours. — (*Berl. klin. Wochenschr*, 1882, No. 3.)

DIGITALINE.—Gr. iss in alcohol et aquæ $\mathfrak{a}\mathfrak{a}$ $\mathfrak{z}$ iss; inject $\mathfrak{m}$ iij— $\mathfrak{m}$ vj = gr. $\frac{1}{8}$ —gr. $\frac{1}{2}$ of digitaline.

EMETIN.—Dissolve gr. iss with a little sulphuric acid in $\mathfrak{z}$ v of aqua; of this, inject $\mathfrak{m}$ viij— $\mathfrak{m}$ xvj = gr. $\frac{1}{2}$ —gr. $\frac{1}{3}$.

EXTRACT OF PHYSOSTIGMA.—Glycerine solution (one part to 60, M. Rosenthal), and in water gr. iiss to $\mathfrak{z}$ i (Eschenburg)—gtt. i–v in Trismus neonatorum.

EXTRACTUM OPI.—Dissolved in water and filtered. Dose of each injection, $\mathfrak{m}$ i–ij= of the drug, gr. $\frac{1}{2}$ —gr. i. — (Lebert).

EXTRACTUM SECALIS CORNUTI AQUOSUM. (Ergotin, according to Bonjean, Ergotinum bis dialysatum).— $\mathfrak{z}$ vi with alcohol, dilut. et glycerin $\mathfrak{a}\mathfrak{a}$ $\mathfrak{z}$ iv; $\mathfrak{m}$ viij— $\mathfrak{m}$ xvj. Ergotinum dialysatum is better adapted for injections (Berg), pure or with water 1 to 4, $\mathfrak{m}$ iij— $\mathfrak{m}$ viiss to the dose. Dragendorff has introduced a *Solution acid. sclerotinici* said to contain the active principle of secale cornut.; gr. $\frac{1}{12}$ —gr. $\frac{3}{4}$ in $\mathfrak{m}$ iij to $\mathfrak{m}$ iij $\frac{3}{4}$ of water.

* And also of all the principal agents used in hy- podermatic medication. If of trustworthy manufac- turers or of proved accuracy of proportion and quickly soluble, they are recommendable.

FERRI OXIDUM DIALYSATUM, FERRI ALBUMINATUM, PEPTONATUM, ETC.—On account of their insolubility, local irritability, and because required to be given for long periods, iron preparations are little adapted to subcutaneous injection. Even the ferrum. pyrophosphor. ammon. citricum, recommended by Huguenin has not proved good in our practice. It is moreover easily decomposed.

HYDRARGYRI ALBUMINATUM (according to Bookhart).—The deposit of Θ ii of the sublimate filtered and washed with blood serum, is with Θ vss of common salt, diluted by water to a quantity equal to 200 grammes or $\Im$ vj- $\Im$ viiij. $\mathfrak{m}$ xv of the solution contains gr. $\frac{1}{4}$ of the sublimate in albumen. Inject Θ vss once or twice daily.

HYDRARGYRI CHLORIDUM CORROSIVUM.—Dissolve gr. $\text{iiij}\frac{3}{4}$ in $\Im$ vi of water and inject $\mathfrak{m}$ xvj once or twice daily, dividing the injection in two different spots (Lewin). Gr. $\text{iiij}\frac{3}{4}$ in $\Im$ iiij $\frac{3}{4}$ of water and inject $\mathfrak{m}$ v-x (gr. $\frac{1}{13}$ -gr. $\frac{1}{8}$ of the sublimate) as a dose (A. Eulenberg). The solution of the sublimate is recommended by V. Bamberger, and the one per cent. hydrargyrum peptonatum. The combination of a one per cent. sublimate solution with 3 per cent. of chloride of sodium is highly spoken of (Lasser, Stern). In all subcutaneous injections of mercury it is absolutely essential that the needle, canula, etc., be subjected to the most thorough disinfection and cleansing, and that the needle be buried in the muscular tissues.

HYDRARGYRI CHLORIDUM MITE (Neisser). Calomel and chloride of sodium, each Θ iv, and water $\Im$ xij. Two injections a week of $\mathfrak{m}$ xv- $\mathfrak{m}$ xxv.

HYDRARGYRI IODIDUM RUBRUM, dissolved in a solution of iodide of potassium (A. Martin). About the following proportions are recommended: Hydrarg. iodidi rub. gr. iv, potass. iodid. gr. xxxvii, aquae destill $\Im$ vi. Inject of this $\mathfrak{m}$ viij- $\mathfrak{m}$ xvj (=gr. $\frac{1}{13}$ to $\frac{1}{2}$ of the drug.)

HYDRARGYRI FORMAMIDATUM (Liebreich.)— $\mathfrak{m}$ xvj corresponding to gr. $\frac{1}{8}$ of the red oxide. For syphilis.

LIQUOR AMMONII ANISATI, pure.— $\mathfrak{m}$ xii-xvj, as excitant.

LIQUOR POTASSII ARSENITIS (Fowler's Solution).—Dilute with 2-3 parts of water; in single doses corresponding to $\mathfrak{m}$ ii-iii of Fowler's solution. Recommended for systematic effect in chorea, tremor and neurosis, by Eulenberg, and for local effects upon malignant new-growths.

MORPHINÆ HYDROCHLORAS.—Dissolve gr. iss in Θ iv of water; of this inject $\mathfrak{m}$ v- $\mathfrak{m}$ xv

(=morphia gr. $\frac{1}{10}$ to gr. $\frac{1}{2}$.) (If in exceptional circumstances greater doses are desired, give a more concentrated solution). Aqueous solutions of morphine are apt to gather mold.¹ Avoid attempting to purify such, and to make them useful by filtering them, because by filtration and the absorption of the filter paper the strength of the solution becomes doubtful. Camphor water instead of pure water is recommended, though the same fungus growth has been observed with this. Still better is to substitute glycerine for water, in the proportion of one to ten parts, and dilute with water when used. $\mathfrak{R}$ morphinæ hydrochlorat, gr. xv, warm with glycer. pur. $\Im$ iiss; dissolve and add aquæ distill $\Im$ iiss. Of this, $\mathfrak{m}$ xv. to $\Im$ iiss=gr. $\frac{1}{3}$ to $\frac{1}{3}$ of morphine.²

NICOTINE.—Dissolve gr. $\frac{1}{3}$ in Θ iv of water, and inject of this $\mathfrak{m}$ iv equivalent to gr. $\frac{1}{8}$ of nicotine.

PILOCARPINÆ HYDROCHLORAS.—Gr. iii in $\Im$ iiss of water, inject $\mathfrak{m}$ xv (=gr. $\frac{1}{3}$ pilocarpine).

STRYCHNINÆ SULPHAS.—Gr. iss in $\Im$ iiss of water. Of this inject $\mathfrak{m}$ iii- $\mathfrak{m}$ x, i. e., from gr. $\frac{1}{45}$ to gr. $\frac{1}{10}$ of strychnine.

TINCTURA CANNABIS INDICÆ (with water).— $\mathfrak{m}$ v- $\mathfrak{m}$ x, in each injection.—(A. Eulenberg.)

TINCTURA OPII.— $\mathfrak{m}$ iii- $\mathfrak{m}$ x, without admixture.

VERATRIN.—Gr. $\frac{3}{4}$ in Θ iv of alcohol, and dissolved in Θ iv of water. Inject of this $\mathfrak{m}$ iii- $\mathfrak{m}$ x, equivalent to gr. $\frac{1}{85}$ to gr. $\frac{1}{2}$ of veratrin. Not well suited for injection.

Subcutaneous Injections for Production of Local Effects.

Hypodermatic injections are also made in order to bring about local irritation in the part, and in this way to produce an antispastic or derivative action (the parenchymatous substitution of Luton). Luton recommends for this purpose sodium chloride, alcohol, tincture of iodine, tincture of cantharides, sulphate of copper, silver nitrate, etc.

More recently the hypodermatic method has been used for the destruction of new growths. The following agents are employed:

¹ NOTE.—All the alkaloids are prone to deteriorate by the growth of a micro-organism in them at the expense of the alkaloid. Fresh preparations are therefore always advisable.

² NOTE.—In injecting morphine great care should be exercised to avoid the vessels, since introduced directly into the circulation severe depression is likely to ensue.

ACIDUM ACETICUM.—Dilute one part of the acid with five parts of water, and inject m xv — m xxv into the growth.—Broadbent).

ACIDUM CARBOLICUM.—In Osteochondroma (Hunter), Naevi (Bradley), Splenic tumor (Mosler).

ARGENTI NITRAS.—Dissolve gr. iss in ℥vi to ℥ix of water. Several syringefuls may be injected into the tumor, and immediately thereafter the same number of injections of of sodium chloride solution (gr. iij to ℥vij of water).—(Thiersch).

IODINE.—Gtt. vj to a syringeful of the undilute tincture in strumous and lymphatic enlargements (Lücke). Instead of the tincture a combination of iodine and iodide of potassium solution, being less painful, may be injected. The proportions would be about these:—Iodi. gr. viiss, potass. iodi. gr. xxxvii, aquæ, ℥xiii . The submucous injection in hypertrophia tonsillarum has very lately been advocated; either a solution of the iodide of potassium one to fifty (Jakubowitz), the combined iodine and iodide (iodine, gr. ii, iodide, gr. xxxvii, water, ℥viiss —Rumbold); or iodine and glycerine (1-2 iodine to 100 of glycerine—B. Fränkel), or a few drops of the pure tincture.

The glycerine solution and iodol is also used.

PEPSINUM in solution has likewise been tried by Theirsch and Nussbaum.

ALCOHOL.—One-half to a whole syringeful in scrofula.—(Schwalbe).

TARTAR EMETIC.—Gr. vj in ℥ijss of water; inject a few drops in cystic tumors of the scalp.—(Kraft-Ebing).

ZINCI CHLORIDUM.—Of the deliquesced salt inject one to three minims.—(Richet).

The experiments of Menzel and Perco to utilize the method of subcutaneous injection for the introduction of nourishment into the system have not succeeded. Fat, milk, egg-yolk, fresh blood-serum, etc., were used, but the quantity of nourishment that could be brought in this way within the reach of the absorbents, was far too little to produce the desired effect of nourishment. V. Ziemssen, however, in anæmia has with apparent success been able to introduce a considerable amount of defibrinated blood (as much as ℥xiii) into the system by the hypodermatic method.

In addition to the above agents, the deep injection of chloroform is advocated by Professor Roberts Bartholow in cases of neuralgia—e. g., of the infra-orbital divisions of the fifth, the sciatic, etc. Whether the neuralgia be superficial or deep, the needle must be thrust deeply, and while obviating

puncture of the nerve itself the chloroform must be introduced near the nerve at its exit from the foramen, pelvis, etc. It is held to be not only palliative but curative. The pure chloroform, or the official spiritus chloroformi U. S. P. may be used. There is temporary swelling and discomfort, but no abscess is formed. m x of the pure chloroform is a full dose.

[Physostigma, or its active principle, eserine, is also recommended for cases of tetanus, strychnine poisoning, etc. The dose is $\frac{1}{10}$ to $\frac{1}{100}$ of a grain. In a solution of gr. iv. to aquæ ℥i , m ii will contain gr. $\frac{1}{10}$ of the drug.]

A Substitute for Iodoform.

Chassaignac (*New Orleans Medical and Surgical Journal*) recommends the oxyiodide (subiodide) of bismuth as an efficient substitute for iodoform. He describes it as of a bright brick-red color, impalpable when well powdered, almost odorless and tasteless, insoluble in water, alcohol, ether or chloroform, and not imparting its color to linen. It may be made, he says, so as to cost only from \$3 to \$3.50 a pound, although ten years ago, when it was recommended by Dr. A. S. Reynolds, its cost was a bar to its general adoption. Dusted on a raw surface, it produces a thin, silvery film, but causes no stinging. The author gives the following formula for its preparation, devised by Mr. J. W. England, and published in the *American Journal of Pharmacy*:

Bismuth subnitrate.	174 grains;
Nitric acid.	3 fluid ounces;
Hot water.	12 “

Dissolve the bismuth salt by the acid in a porcelain capsule with the aid of heat, and add the hot water gradually, stirring after each addition; then add the solution gradually to a solution of 663 grains of potassium iodide in twenty-eight ounces of hot water, agitating well after each addition. The agitation should be continued until the decomposition is complete; then the precipitate should be filtered out at once, washed with warm water, dried and powdered.

Urticaria from Bed-Bugs.

A. H. Ohmann-Dumesnil, in the *St. Louis Medical and Surgical Journal*, July, 1887, says: “My attention has been more particularly called to this subject by having noticed several similar cases at comparatively short intervals. It is a well-known fact that the ordinary bed-bug (*cimex lectularius*) produces a wheal which is of a burning, itching

character, and marked by a very small, almost imperceptible puncture near the central portion. The animal itself is not always confined to beds, but occasionally roams abroad, and, in consequence, when it seizes upon its host, is proportionately more voracious on account of the scarcity of food which it finds. Along the edges of water-closets, especially those adjoining sleeping rooms, it is no uncommon thing to find these odorous pests. They lie in wait for their victims and, whilst very insidious in their method of attack, produce large and troublesome wheals in the popliteal space and neighborhood. The victim has urticaria suddenly and then cudgels his brain as to its probable cause, little suspecting that an unseen foe has attacked him. By lifting the cover of the water closet, which is near the bowl, the "bugs" can be discovered. Then when nature drives one again to the closet, introduce a piece of paper between the body and seat, and upon removing it the animals will be found upon it. Carbolic acid, corrosive sublimate or, better still, camphor-phenique liberally distributed about their haunt will eventually destroy these disturbers of the peace of a contemplative nature."

Picrate of Ammonia in Malarial Fevers.

Dr. E.S. Fuller presents the following interesting note in the *New York Medical Record* of July 2, 1887: Having been for many years a sufferer from chronic malaria, and being at the time afflicted with an unusually severe attack, for which I had taken the usual remedies without receiving any benefit, I at once procured some of "Merck's" picrate of ammonia and began its use in half-grain doses (made into a pill with extract of gentian) three times a day. In three days' time there was marked improvement in all my symptoms. Had no more chills, pain in head and back had left me, and I awoke in the morning without those terribly exhausted and irritable feelings which those who suffer from this disease so well know. This result encouraged me to make trial of the drug in several cases of similar trouble in which I had been using quinine, etc. I prescribed it for six adults, of both sexes, and kept watch of the effect. In all but one case the same marked improvement speedily resulted. I now began to notice a peculiar, deep-orange color in my urine, without any change in quantity, and a chemical analysis of it showed that except for the change in color it was normal. Upon inquiry I found that the urine of all the patients was of this same orange color.

Having taken the medicine myself in doses as above mentioned for ten days, I decided to stop its use and watch for the disappearance of this color from the urine. To-day, May 24th, seven days since stopping the medicine, there is not the least improvement in the color of my urine, and the whites of my eyes and the skin of my face generally, are the color of one mildly jaundiced. The same thing has occurred to all my patients who have taken the remedy for a week. One lady, to whom I gave the maximum dose, one and a half grains three times a day for eight days, is now deeply jaundiced, the color involving not only the whites of the eyes and the skin of her face, but also the skin of her neck and breast, from which, shading to a lighter color, it covers the rest of her body. In each case the tongue is clean, bowels not affected and appetite good. I do not understand why the discoloration of the urine remains so long after stopping the medicine, or why it should cause discoloration of the skin at so late a day.

Eczema Papulosa Contagiosa, or Prairie Itch.

Dr. H. J. Warmuth, in the *Nashville Medical News*, July 1st, 1887, says:

Eczema is generally described in the textbooks as a non-contagious affection of the skin; my two years' experience with this dermatosis, however, convinces me that the present eruption is contagious, and has been gradually propagated from one neighborhood to another, until we find it diffused, not only over some of the Southern, but also Eastern States. By a tacit understanding among the people of the invaded States, it has been named "the itch," *par excellence*, and on the prairies "the Prairie Itch;" but everywhere the symptoms, course, and finale of this affection seems to be the same.

What is the cause of the present contagious form?

Prior to the last, we had two very severe winters, something rather unusual in this latitude. People had to house and clothe themselves more carefully, and hygienic measures were generally grossly neglected among the lower classes, from whom the present affection received its first impetus. Wearing heavy flannels for weeks and perhaps for a longer time, without proper ablutions and without frequent change of under-clothing, must necessarily produce an irritation and congestion of the skin, which sooner or later, assisted by the unavoidable scratching of the itching surface, will form an eczematous eruption, which with all disregard to cleanliness is destined to advance

to other stages, and to contribute to the extension and persistence of the eruption. The clear yellow serum contained in the minute vesicles will, under these circumstances, undergo a change in its chemical nature that will undoubtedly favor the formation of parasites. This theory will probably explain the contagiousness of this affection. In all cases, the patient's themselves could trace their affliction back to friends with whom they slept or whose clothes they wore. If our microscopists would investigate this matter, our doubts would soon be at rest.

Acting under the idea that our eczema papulosa was of a parasitic nature, I adapted my treatment accordingly and met with great success.

Where the patients presented only an irritable and congested skin, *i. e.*, in the first stage, I merely ordered the patients to use inunctions with lye soap (sapo viridis would be better) all over the body at bedtime, and in the morning to bathe with warm water. Blue mass whenever needed; if not, then sulphate of magnesia, three drachms in a wineglass full of water before breakfast. Continue the soap every other night; the salts every morning till well. This was generally sufficient to cure the first stage.

As soon as the vesicles appear upon a tense, swollen, and red surface, they soon increase in size and become filled with limpid serum. In mild cases and under appropriate treatment, the serum is absorbed, the vesicles dry up and form either thin crusts or scales, which soon fall off and leave the skin red and tender. In this stage I prescribe:

R Plumbi acetatis
Acidi carbolicii..... āā 3 iij
Extract. belladon. fluid..... f 3 ss
Glycerini..... f 3 iij
Aquæ q. s. ad..... f 3 x

M. Sig.—Apply soft cloths moistened with this solution to the affected parts. When dry moisten again and keep moist.

This soothing solution will act like a charm and subdue the severe itching and burning. Internally I prescribe:

R Magnesie sulphatis..... 3 iv
Elixir vitrioli..... f 3 ss
Tinct. gentianæ..... f 3 iij
Aquæ q. s. ad..... f 3 iij

S.—A teaspoonful in wineglassful of water after each meal.

In anæmic cases I add ferri sulphatis gr. xvi to the above. This mixture will keep the contents of the bowels in a soluble state and disperse cutaneous congestion. It also acts as a mild tonic.

As soon as the vesicles burst the eruption becomes confluent, forms dark-brown crusts, and leaves an unhealthy state of ulceration under it, I change the external treatment. The ichor in these cases is generally so irritating that under the crusts ulceration is deepening. Where I find crusts, I order poultices to remove them; but if already removed, I give my patients the following:

R Acidi carbolicii..... 3 ij-ijj
Zinci oxidi..... 3 ij
Cosmolini (vel vaselini)..... 3 ij
M. ft. ungt. Sig.—Anoint two or three times a day.

Sometimes I use the ungt. hydrarg. amoniat. of the U. S. D., with carbolic acid, and with equal success.

I continue the saline mixture, but should the patient need a bitter tonic, I prescribe elix. calisaya, strychnine, and iron.

In all stages, I insist upon frequent ablutions and change of underclothing.

Interesting Points About the Teeth.

The *Boston Med. and Surg. Journal*, July 7, 1887, contains the following interesting items:

Four sets of teeth before the age of fifteen years.—A child, under the care of Dr. Gatching, developed the first set of teeth at the age of six months. These teeth were all shed at nine months. At eleven months, she began teething again, another set of teeth being erupted in four months. Six weeks after, these teeth began to crumble, and were entirely lost. Her weight at this time was ten pounds. At thirty months the third set appeared, and these remained till the age of four years, when they were extracted. The fourth set began to erupt at eleven years, and the dentition was complete at fifteen.

Planting teeth in artificial sockets.—Dr. Younger has invented this new operation. When a tooth has been lost he drills a suitable hole in the alveolus. Into this hole, which should be of the same shape as the root of the tooth to be planted, he forces the tooth, which has been previously filled and soaked in a solution of bichloride of mercury in water, of a strength of one to a thousand. In most cases no ligatures are required to hold the tooth in position. There is little soreness of the parts, and in a day or two the tooth feels like the others in the mouth. Younger considers a tooth which has been out of the mouth for several years as good as a recently extracted one, as the root-membrane retains its vitality as do seeds. There are two dangers in the operation: First, one may transmit syphilis or other dis-

ease; Second, the planted tooth has no living pulp and is more liable to decay, and, like all pulpless teeth, may ulcerate. The writer has examined the teeth of sheep with the view of dissecting out the incisors of a freshly killed animal of the proper age to have the roots unclosed. The pulp in these cases is large, and if properly cut off and inserted into the human jaw ought to go on growing. If this should happen, the roots would close and the tooth would then be a living tooth, instead of a pulpless one. By cutting off the ends of the crowns of a sheep's incisors, these would answer very well for this purpose, and if Younger's operation is really a successful one as tried by three or four years' time, this experiment will be made.

The importance of regularly examining the saliva.—Now that we know that decay in the teeth is due to acids formed from fermenting substances, the importance of keeping the saliva alkaline cannot be overestimated. If it is acid or neutral, it cannot neutralize the acids formed in fermentation, which collecting in the spaces between the teeth and about their necks, are certain to produce decay. The patient should be taught the use of litmus paper, and directed to test the reaction of the mucous membrane and parotid saliva at least once a week. If the reaction is acid, he should take the remedies found appropriate to his case. Fermentation takes place in every mouth, and yet there are many persons in whose mouth decay is either wanting or is what may be called accidental. In all such mouths the reaction of the saliva is always alkaline.

Agaricin as Used in Bellevue Hospital.

Agaricin (the active principle of *agaricus albus*) gives uniform results in checking excessive perspiration in phthisical and fever patients. The following formula is used at Bellevue Hospital:

R.—Agaricini (Merck).....gr. x.
Atrop. sulph.....gr. j.
Acidi sulph. arom.....℥ 1200
Dissolve and filter.

Dose ℥ x, containing $\frac{1}{2}$ gr. agaricin, $\frac{1}{10}$ gr. atrop. sulph. and ℥ x arom. sulph. acid. To be administered in syrup of simple elixir.

It may also be advantageously given in pill form, combined with Dover's powder. Thus:

R.—Agaricini.....gr. ij.
Pulv. Doveri.....gr. xxv.
M. Ft. pil. No. xx.

Sig.—One pill five or six hours before retiring or sweat comes on. Its action is slow, hence the necessity for giving it early.

—*Quarterly Bulletin*, April, 1887.

Injection of Sulphuretted Water for Phthisis.

In connection with the article by Prof. H. C. Wood in the *REPORTER*, May 28, 1887, it is interesting to note that Dr. H. A. MacCallum, of London, Ontario, has found enemata of water, charged with sulphuretted hydrogen, of use in this disease. In an article in the *Medical News*, July 23, 1887, Dr. MacCallum says:

I inject the watery solution into the bowel, depending on the mechanical and physiological action of its mucous membrane to free and absorb the gas. A perfectly saturated solution is prepared (not less than eight hours should be taken for saturating cold water with sulphuretted hydrogen gas), of which $\mathfrak{z}$ vij are diluted with $\mathfrak{z}$ xx-xxx of water, and securely corked in ale-bottles. The contents of one of these, night and morning, after warming to 90° , are slowly injected into the bowel; not less than thirty minutes should be taken to do this. It is necessary to observe such precautions as would be taken in rectal alimentation, viz., the exclusion of air, the compression of the sphincter ani with the fingers, and afterward by directing the patient to extend the lower limbs. With some patients I precede the solution with laudanum. The majority, after gaining skill and confidence, retain the solution altogether.

As to results: The profession will be disappointed if they look for a "positive cure from phthisis" in this remedy. In no single case have I used it alone, and any results that were extremely favorable might not be wholly ascribable to the rectal mode of treatment.

I would not be surprised to find that the mass of the profession, who are now giving, or about to give this drug a trial, will discard it as worthless, because they are looking for results I feel sure they can never obtain. I think I am fair when I say to patients who have troublesome pains in the chest, expectoration of vast quantities of muco-purulent matter, and but slight loss of flesh, that it is a remedy of great value. Its tendency to disorder digestion, however, greatly diminishes this.

I have seen three toxic cases. The symptoms of Miss A. will answer for all. She took $\mathfrak{z}$ xij, properly diluted, in three minutes. Five minutes after she complained of oppressive breathing. Her face became pallid, and "her eyes turned up." She passed rapidly into a state of syncope, from which she revived by feeble efforts at vomiting. The solution was still in her bowel when I was called to see her. I ran it off with a hard rubber tube, and gave her brandy. One

hour after I found her recovered with the exception of some gastric disturbance, pulse 108, temperature 97°. All three rapidly recovered; had subnormal temperature and gastric trouble for two days. Some patients bear 3xx diluted without trouble, if more than thirty minutes be taken for its introduction.

I prefer the solution to the gas for the following reasons:

1. The dose is uniform. In Bergeon's method the dose depends on the temperature and strength of the solution.

There is no apparatus wanted except a household syringe. I generally prepare several bottles at a visit, directing them to be kept in a cool place. The nurse can prepare the bottles, and in this way patients at a distance can be easily treated.

3. The solution causes less pain to the patient; if it is rejected, another bottle can be used.

4. There is no call for the use of carbon dioxide—a gas considered valueless, and contra-indicated. To say CO₂ is antiseptic is contrary to all physiological truths, and if it possesses any value in phthisis it is due to its sedative action. The blood appears to take up oxygen more rapidly after its use, but even this action is only temporary.

5. Bergeon failed with chlorine gas. I was able to give it in solution and found it well borne. I did not give it for any time, fearing it had a tendency to produce anæmia, by combining with the iron in the hæmoglobin.

Counting the Ribs.

Physicians are frequently mistaken in counting the ribs. One must never start at the clavicle. We must start from the suprasternal notch, obliquely and below which is the first intercostal space. Or again by palpation of the sternum the first projection is the junction of the first and second piece, at which we find the articulation of the second rib. One is sometimes astonished at the space between the clavicle and third rib. One forgets the breadth of the first rib.—*Canada Practitioner.*

Charcoal and Camphor.

A mixture of equal parts of camphor and animal charcoal is recommended by Barbocci for preventing the offensive odor and removing the pain of old excavated ulcers. The camphor is stated to act as a disinfectant, and the charcoal absorbs the offensive odors.—*British Medical Journal.*

CORRESPONDENCE.

Bergeon's Method.

EDS. MED. AND SURG. REPORTER:

Sirs: In the number of the REPORTER for July 2nd, and on page 35, I saw an "Item" in regard to Diogenes. Now, if you see the old man dodging around with his lantern, you can send him to Philipsburg, and he can find two doctors who have never given gaseous enemata.

Philipsburg, Pa.

[We are glad to be able to say that in the next issue of the REPORTER there will appear a short practical paper by a physician who has been giving Bergeon's injections daily for some months. It will give all the details of the operation, with directions for "home made" apparatus.—EDITORS OF THE REPORTER.]

An Unusual Symptom.

EDS. MED. AND SURG. REPORTER:

In the REPORTER of April 9, 1887, p. 450, under the heading, "A Country Doctor's Record," by G. Law, M. D., of Greely, Colorado, a case of labor is reported in which the Doctor says: "Mother had a very extensive prolapsus ani and prostatitis." I would be glad if the doctor, through your journal, would give us the symptoms which led to the diagnosis of *prostatitis*, as I have never seen a case of the kind reported or heard of one before. Indeed, I have been led to believe that, from some anatomical considerations, such a case could not exist. A little light on the matter, by the doctor, will be gratefully acknowledged by another country doctor, who has been a subscriber to the REPORTER for several years.

[The communication referred to was published in the REPORTER three weeks before the present editors assumed control. The error quoted must have been due to a printer's mistake, which eluded the vigilance of the proof-readers. Dr. Law, no doubt, meant "proctitis"—not "prostatitis."—EDS.]

Atropia Injections for Gonorrhœa.

EDS. MED. AND SURG. REPORTER:

Sirs:—I wish to call the attention of your readers to the value of urethral injections of sulphate atropia in urethral and vesical irritability produced by gonorrhœa. Where gonorrhœa is accompanied with much vesical irritation, frequent urination and tenismus, I find the symptoms speedily relieved by an injection of $\frac{1}{4}$ to $\frac{1}{2}$ gr. of sulphate atropia, in one or two drachms of

water, pressed gently along the urethra into the bladder. I have resorted to this method in several cases with the happiest results. I also used it in a patient who had taken an over dose of cantharides, which produced great vesical tenesmus and pain in passing water. One injection gave immediate relief. I leave the injection in the bladder, and have never seen any poisonous effects from the drug. I think it superior to the salts of cocaine, as the effects are more lasting. If any of your many readers have used the atropia as I have above directed, I would be pleased to hear of their results.

D. W. BOONE, M. D.

Bellaire, O., July 13, 1887.

Treatment of Stomatitis.

EDS. MED. AND SURG. REPORTER:

Sirs: The root of sumac (*rhus glabrum*) has a thin outer dark-colored bark. Under this there is a thick white bark, easily shaved from the wood. This, when dried, keeps well. Make an infusion, or even a decoction, of it. The latter is a mucilaginous mixture without taste or smell; and it is an excellent remedy in cases of stomatitis, discounting chlorate of potash, and all other irritating washes.

BACK WOODS.

[The above is from a subscriber in Canada, in whose judgment we place great reliance; and we recommend to our readers the simple remedy which he suggests.—EDITORS OF THE REPORTER.]

A Correction.

EDS. MED. AND SURG. REPORTER,

Sirs:—In my communication on Quinine in the REPORTER of May 21st, I referred to a doubt expressed by Dr. Holmes whether the mere *reduction of temperature* is of any value in febrile affections. Instead of "temperature," it should have been *pulse rate*.

HIRAM CORSON, M. D.

July 26, 1887.

NEWS AND MISCELLANY.

Medical Matters in Vermont.

(FROM A SPECIAL CORRESPONDENT.)

The Medical Department of the University of Vermont, at Burlington, held its Thirty-fourth Anniversary on the 18th ult. The examinations of the class, which numbered seventy-nine, took place the week previous, and was a very thorough and exhaustive one. Of the number that presented themselves for graduation only fifty-three passed and received

the degree of the college. Among those who were "plucked," as the term is, was a gentleman from the Pacific Coast, who held a bogus diploma from some foreign medical college, and has been practicing medicine under it for some years. He was at the head of a Woman's Hospital in one of the cities in that region and a teacher in Gynæcology. He was very familiar with the president, faculty and dignitaries of the College, and in the social circles of the city. As he was somewhat patronizing in his attendance upon the lectures, some surprise was expressed that he did not receive the honors of the college, having come so far, and made such a demonstrative effort; but he was found lamentably deficient in his examinations. The examination in chemistry is understood to have been the most difficult and the least practical. The "plucking" of so large a proportion of the graduating class is a good indication. It indicates the elevation of the standard of medical education, and if continued and the example followed by all the medical colleges in the country, it will give the people a better and more intelligent class of medical practitioners, much needed to stem the tide of quackery which is pouring in upon us from every direction.

The graduating exercises were held in the Howard Opera House, and it was well filled with an appreciative audience. The degrees were conferred in a very imposing manner by President Buckham. The prizes of \$50 and \$25, and the "honor man" of the class were announced by Prof. A. P. Grinnell, Dean of the Faculty, and the "Valedictory" was safely delivered by J. C. O'Brien, amid the congratulations of the audience and the exalting strains of sweet music by the Opera House Orchestra. Following these exercises came the elegant scholarly address of ex-Senator Patterson, Superintendent of Public Instruction of New Hampshire. It was listened to with deep interest. No abstract of it would do justice to it. The usual banquet and reception was held at the Van Ness House, was participated in by some one hundred and fifty people, and with its menu, after-dinner speeches, music and songs continued to a late hour.

The State of Vermont has a State Board of Health, but so little has been heard from it, that the people have hardly yet found it out. In making the appointments for members of the Board the Governor seemed to ignore the physicians and others who had taken the most interest in its establishment, and hence it lacks the enthusiasm and vigor which is needed to make it a success. O. P. Q.

The Wholesomeness of Swill-Milk.

Dr. Geo. H. Rohé writes as follows in *Science* of July 22d:

The discussion carried on in the pages of *Science* for some weeks past upon the healthfulness of milk from cows fed upon distillery-swill has, in my opinion, failed to definitely settle the question. There can be no doubt of the vital importance of the matter, and all physicians and sanitarians will agree that a solution of the problem is highly desirable.

1. I venture to say that no positive evidence has been submitted showing any ill effect of swill upon cows fed with it. The evils attributable to it are largely, if not entirely, to be ascribed to the unsanitary surroundings of the animals.

2. Whatever evidence has any positive value indicates that swill is equally as good and proper food (used with judgment) as hay, dried fodder, ensilage, or bulbous roots. These all differ widely in chemical composition from the green foods (grass, clover, green oats, and corn), which may be looked upon as the normal food of cows.

3. It may be worth while remembering that lactation in a dairy is not a normal process. Dairy-cows are "milk-machines." The dairy business would not be very profitable if lactation were not forced to some degree.

4. Experienced agriculturists, like Professor Armsby and Dr. Sturtevant (*Science*, ix. pp. 602-3), have failed to see any ill effects attributable entirely to swill, and such veterinarians of ability as Professor Law and Dr. Salmon (*Ibid.* p. 552) corroborate this testimony.

5. The facts collated by Professor Brewer (*Ibid.*, p. 550), showing the ready absorption of germs and odors by milk, the transmission of the flavor of various odoriferous substances eaten by the animal to the secretion, the passage of certain drugs administered medicinally into the milk of nursing women, or the notorious fact that swill-milk stables are "proverbially foul and stinking," have no bearing upon the case. The evidence required to establish the unwholesomeness of swill as food for milk-giving animals must be of a different character.

6. While it may be conceded that "chemical analyses will not settle the question" of the wholesomeness of swill-milk, the fact remains that we have at present no other way of determining the physical qualities of a specimen of milk. Bacteriological investigation may determine the presence of the germs of tuberculosis, typhoid, and, in view of recent discoveries, of scarlet-fever, but

will not enable us to ascertain the relative proportions of the saccharine, fatty, aqueous, or proteid matters present. Chemistry is here still our main-stay, and, other things being equal (more definitely, disease-germs being absent), a specimen of milk nearly approaching the chemical standard established by Koenig may be looked upon as a wholesome food. Other factors besides the food of the animal enter into the production of milk. The age of the animal, period of lactation, time when the milk is drawn, and general sanitary condition, must not be ignored.

7. The asserted greater firmness, and consequent indigestibility, of the coagulum in swill milk is not based upon a sufficient number of observations to admit of unquestioned acceptance. It should be easy to determine this in any chemical laboratory. No single series of observations would decide this, however. It would be necessary to test milk from cows fed upon swill but kept under good sanitary conditions, side by side with milk from animals kept under the ordinary conditions of city stable-life, and fed upon various foods.

8. A scientific solution of the question will not be furthered by prejudiced appeals or unreasoning denunciation. Patient investigation, keeping in view all circumstances of the question, and avoiding all one-sidedness in considering the matter, will alone bring about the object desired. Personally I at present occupy the same standpoint as Professor Armsby (*Science*, x., p. 4), "Much of the common prejudice against the use of distillery-slops appears to be occasioned by their irrational application, and frequently by the filthy surroundings of the animals, rather than by anything injurious in the feeding-stuff itself."

Leeches.

The first to employ leeches was Themison, a physician of Laodicea and contemporary of Pompey. He was also the founder of the sect of the Methodici, and is often cited as an authority, especially by Caelius Aurelianus. Dr. Greenhill distinguishes him from the Themison satirized by Juvenal (x., 221), who, it being then the custom with artists of every kind to assume the name of celebrities in the same walk, no doubt called himself after his distinguished predecessor. This assumption of names is one of the many difficulties besetting the historian of ancient medicine.

Loco Weed.

This plant, a pest in many parts of the extreme Western States, is said to act as an intoxicant to animals that feed upon it. We note that Prof. L. E. Sayre, of the Kansas State University, Department of Pharmacy, in connection with others, and the Board of Agriculture of that State, are investigating the physiological effects upon animals.

"A Bone of Contention."

A surgical case of much interest, which is reported as having occasioned a heated discrepancy of opinion among the attending physicians who were called in to decide its nature, recently occurred in St. Louis. A man fractured his thigh while pulling off his boot. An incision was made and a "ragged break" of the bone presented. Five of the physicians diagnosticated the existence of sarcoma as accounting for the occurrence of the fracture from so trivial a cause, and advised amputation. But Drs. Eisler and Franklin protested that sarcoma was not present, and submitted their side of the controversy to Dr. Agnew, of Philadelphia, who wrote that fractures, while rarely the result of such a cause as was claimed to have produced it in this case, might so result. Microscopic examination of these tissues, however, substantiated Dr. Eisler in his opinion of the case.

Items.

—Pittsburg physicians claim that a young man of that city died from the effects of a patent anti-fat.

—The State Medical Society of West Virginia held its twentieth annual meeting at Greenbrier, White Sulphur Springs, West Va., July 13th to 15th, 1887, inclusive.

—Dr. Sidney Ringer, F. R. S., has been appointed the successor of the late Dr. Wilson Fox to the Holme Professorship of Clinical Medicine at University College, London.

—Dr. Morris Longstreth recently showed the class at the Pennsylvania Hospital some cases of tonsillitis which had simply been treated by applying turpentine stupes to the neck, with gratifying results.

—An interesting anatomical anomaly was recently presented to the New York Obstetrical Society, by Dr. Grandin. There were two humeri in the right arm, and three radii and ulnæ, with three right hands.

—M. Gayon and Dupetit at a recent sitting of the French Academy, presented a

method for preventing the secondary fermentation in the production of alcohol, to which the formation of the higher alcohols are due. It was the addition of bismuth salts to the fermenting fluid, they claimed, that thereby only the pure ethylic alcohol was generated.

—The editor of the *Denver Medical Times* in an excellent article against abortionists says: "The attitude of the church is very indifferent on this question." Such suggestions do great injustice to both Catholicism and Protestantism. The Roman church as well as the Methodist Episcopal, Protestant Episcopal, Baptist and Presbyterian churches speak with no uncertain sound on this question. We of the medical profession should first thoroughly remove the beam from our own eyes before we tackle the mote that darkens the moral vision of any weak theologian.—*Southern California Practitioner*.

—Dr. J. Bell, of the Inland Revenue Laboratory, London, seeking for a practical method for distinguishing between horse-flesh and beef, has shown that the usual physical appearances relied upon by the inspector of slaughter-houses at Paris are not certain. He observed that the adipose tissue of the horse was of a softer and more oily nature than that of beef. Upon experiment, he found that horse-fat at 70° F. formed a clear oil, and the amount of solid fat deposited at lower temperature was comparatively small. The melting point of beef-fat varied between 110° and 116° F. The specific gravity of horse-fat at 100° was 0.9084 to .9088, while, with beef-fat, it was 0.9036 to .9040. This difference affords a positive means for distinguishing horse-flesh from beef.

OBITUARIES.**DR. WILLIAM S. LITTLE.**

DR. WILLIAM SEELY LITTLE was born in New York City, December 17, 1848. He was graduated at Princeton College in 1868, and at Bellevue Medical College in 1870. He afterwards served as resident physician at Bellevue Hospital and at Mt. Sinai Hospital, New York. He also held various appointments in other institutions in New York city, among them one in the Eye Infirmary. During this period he was associated as assistant, both in public and private work, with Dr. Henry D. Noyes, with whom he was connected by marriage. It is to this association that his early interest in ophthalmic surgery is to be ascribed. In 1873 he went to Europe, and spent nearly a year in study, devoting himself especially to

diseases of the eye. Shortly after his return, September 17, 1874, he married Miss Mary U. Wilson, a daughter of Dr. Ellwood Wilson, of Philadelphia; and the following year, resigning his appointment in New York, he removed his residence permanently to Philadelphia. After a short time spent in general practice, in which he gave promise of unusual success, he yielded to the bent of his inclinations, and began to devote himself exclusively to the eye. In 1877 he was graduated at the Jefferson Medical College, and was thereupon appointed chief assistant to the eye department at the Jefferson Hospital, and ophthalmic surgeon to the Church Home at Angora. These positions he held until his death, which occurred February 17, 1887, after a slowly progressive illness of three years.

This is a brief and incomplete history of one of nature's noblemen, who the writer believes sacrificed himself on the altar of his profession. After his premonition of lung trouble, often have I urged him to give up his laborious positions and remove to a clime more congenial to his health, and at the same time lessen his labors. This he was always promising and intending to do, but, alas! he postponed it too long, feeling that he could not give up such a valuable field for study as his hospital positions. He died in the prime of life, and on the verge of what promised to be a useful and distinguished future. Refined, generous, honest and candid, he was never happier than when assisting others, either in or out of the profession. To esteem him properly one must have known him well, and the more he was known the more he grew upon any acquaintance he ever made. WM. B. ULRICH.

Chester, Pa.

DR. E. D. STANDIFORD.

Dr. E. D. Standiford died at his home in Louisville, July 26th, 1887. He died suddenly and peacefully, retaining his faculties to the last. Dr. Standiford had been a candidate for the United States Senate for several months. Dr. Standiford was born December 28th, 1831. He was married three times and leaves seven children. His last marriage was on July 7th, and he had not been out of the house but three times since the wedding. Dr. Standiford was the most prominent capitalist of Louisville. He served several times in the state senate and was a member of the Forty-third Congress. He was president of the Louisville and Nashville Railroad. His fortune is placed at two millions.

DR. JOHN C. LEVIS.

Dr. John C. Levis, one of the best known physicians in Western Pennsylvania, died at his residence in West Bridgewater, July 27th, 1887, aged 58 years. When the war broke out he was made surgeon of the 58th Regiment. He was transferred to several other regiments, and was finally stationed at Pittsburg as post surgeon. He established the Government Hospital in that city. He also had charge of the Government hospital at Chambersburg during a portion of the war.

J. D. WARREN, M. D.

Dr. J. D. Warren, of Meduaia, N. Y., one of the most prominent physicians of Orleans County, died on the 10th inst., of Cirrhosis of the Liver. His age was 56 years. Dr. Warren was a man of magnetic presence, and made friends whose kind regards and good wishes he always retained. He was a most delightful companion and possessed generous qualities which will never be forgotten by those who knew him. In accordance with his wishes his remains were cremated in Buffalo on the 13th of July.

There have been no changes in the Medical Corps of the Navy for the week ending July 30, 1887.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from July 24, 1887, to July 30, 1887:

Col. D. S. Magruder, Surgeon, granted leave of absence for one month, to take effect on or about August 10, 1887. S. O. 170, A. G. O., July 25, 1887.

Major D. G. Caldwell, Surgeon; order relieving him from duty at Ft. D. A. Russell, Wyo., and assigning him to duty at Ft. Assiniboine, Mont., is revoked. S. O. 168, A. G. O., July 22, 1887.

Major P. J. A. Cleary, Surgeon, ordered to Ft. Assiniboine, Mont., instead of Ft. D. A. Russell, Wyo. S. O. 168, A. G. O., July 22, 1887.

Major Ely McClellan, Surgeon, detailed as member of a board of survey to meet at the Medical Purveying Depot, St. Louis, Mo., on August 1, 1887. S. O. 173, A. G. O., July 28, 1887.

Capt. S. G. Cowdury, Asst. Surgeon, granted one month's leave, to take effect on or about July 24. S. O. 79, Dept. Texas, July 13, 1887.

Capt. H. G. Burton, Asst. Surgeon, sick leave of absence extended three months. S. O. 171, A. G. O., July 26, 1887.

Capt. E. T. Gardner, Asst. Surgeon, ordered for duty at Ft. Reno, Ind. T. S. O. 170, A. G. O., July 25, 1887.

1st Lt. C. S. Black, Asst. Surgeon, ordered for duty as Post Surgeon, Ft. Bliss, Tex., during the absence, on leave of Capt. S. G. Cowdury, Asst. Surgeon. S. O. 79, Dept. of Texas, July 13, 1887.

1st Lt. W. D. McCaw, Asst. Surgeon, ordered for temporary duty at Ft. Riley, Kan. S. O. 78, Dept. Mo., July 25, 1887.

ORIGINAL DEPARTMENT.

LECTURE.

ST. LOUIS COLLEGE OF PHYSICIANS
AND SURGEONS.—SURGI-
CAL CLINIC.

SERVICE OF LOUIS BAUER, M. D., M. R. C. S.,
ENGLAND, DEAN, PROFESSOR
OF SURGERY.

Reported by George W. Cole, M. D., Assistant Dem-
onstrator of Anatomy, and Assistant to
the Chair of Surgery.

CASE I.—Fibrous ankylosis of knee-joint ;
angular contraction ; *brisement forcé* ; un-
successful exsection of the articulation ; re-
covery, with a serviceable, but ankylosed
limb.

This little patient has but recently arrived
from Berlin, where Prof. Gueterbock had
charge of her case, and assigned her to Prof.
B. R. M. ; is but five years of age, and has
been an invalid during half of that time. She
exhibits, consequently, the marks of contin-
uous suffering, being pale, anæmic, and re-
duced in weight.

The proximate cause of her trouble is not
known, and the tenderness of the knee-joint
was only incidentally discovered by her
mother. For a while she was treated by
competent surgeons in Berlin ; but relief was
only temporary, and her disease advanced
slowly until the time when she was received
at our clinic.

The knee was found enlarged and altered
in shape. There was pain on pressure and
motion, and intense reflex pains during the
night. The joint was moveable through an

arc of about 25° , and the leg was bent at a
right angle to the thigh. The patella was
adherent to the external condyle of the femur.
The toes were everted, and there was pro-
nounced contraction of the biceps muscle
of the leg. There were several old cicatrices
marking the site of former fistulous open-
ings. As far as we could learn, the case had
been set down as tubercular or fungoid arth-
ritis, and treated accordingly ; yet no inher-
itance of tuberculosis could be proved. Both
of the girl's parents and their children were
perfectly well and certainly free from tuber-
culosis.

Prof. Bauer is of the opinion that physio-
logical rest to the affected joints, in proper
position of the limb, is the most efficacious
mode of treatment, and he decided to divide
the biceps muscle and to forcibly extend the
limb, under anæsthesia, and afterward to fix
it in a correct position. He had some fear
that the existing cicatricial tissue might re-
sist and mar the result ; and the issue justi-
fied his fears. The contraction and malposi-
tion of the limb could not be completely re-
duced, and therefore physiological rest was
not fully obtained. The pain was lessened,
but not overcome, and very soon suppurative
foci were discovered, obviously emanating
from the mechanical interference with the
inter-articular adhesions and the scars which
bound the skin to the bone.

All these efforts developed and advanced
to a degree which would have put the life of
the patient in jeopardy. Under these cir-
cumstances, exsection of the knee suggested
itself as the most appropriate remedy, and it
was promptly resorted to. The operation
was done aseptically. An anterior semilunar

flap afforded a full view of, and access to the joint. It was found necessary to remove a slice from each bone, to excise the already eroded patella and to drill the internal condyle of the tibia to the extent of about half an inch. The limb was placed in an iron splint with a foot board, and its position was made so secure that no displacement could occur. During the following week there was some constitutional disturbance. The temperature rose, and the pulse at one time rose to 153 beats per minute. These symptoms soon gave way, and a calm, progressive reconstruction followed. No medication of any consequence was resorted to. The most nutritious diet was almost exclusively depended upon. The exsection was performed on March 28, and to-day, June 6, the patient is virtually convalescent and will soon be allowed to walk.

The femur and the tibia are firmly united by bony structure. There is not the slightest mobility at the knee. The child has improved in weight and in appearance.

CASE 2.—This case is almost identical with the previous one, the only difference being in the age of the patient (26 years), and in the cause, which was a traumatism, (a fall upon the knee).

The patient was just 12 years old when she met with this accident; and, as is usual, it was not appreciated until the disease had become so grave as to compel her to desist from using the limb.

For 14 years various treatment was employed for the presumed strumous disease; but the disease advanced, abscesses formed, fistulous tracts opened, mobility gradually diminished, and contraction of the biceps muscle followed.

When the patient presented herself at the clinic of Prof. Bauer, the knee joint was in a condition similar to that in the preceding case, except that tenderness was not quite so pronounced, although sufficient to interfere with the use of the limb.

For the reasons already assigned, *brisement forcé* was instituted after the division of the biceps tendon; but in spite of all efforts the limb could not be fully extended.

For a month inflammation and suppuration ensued, and then resection was performed. Ever since this operation the patient has done well. The limb is almost straight, the wound is almost wholly cicatrized and perfect recovery in a very short time is expected.

In either case the condition of the joint was such as to yield to no other measure but

resection. In both, the patella was eroded and its removal necessary.

In Case 2, the external condyle of the tibia was excavated, the cartilage was destroyed, and the bone in a state of superficial disintegration. In neither case was any medication used except a few anodynes; while the patients were built up with concentrated and nutritive food.

In regard to the so-called strumous diathesis, and the tubercular bacillus, Prof. Bauer remarked that he doubted that cases such as these had any connection with constitutional depravity. For the disease started in but one articulation, and ran its course to the end without implicating other joints or localities, except by the septicæmic process engendered by the local disease.

Constitutional affections of the joints are rare, always multiple and fatal in the end. A large number of cases of this class, which have come under Prof. Bauer's observation have confirmed his opinion that most joint affections, especially the monarticular ones, are of a strictly local origin and character, requiring appropriate local treatment; removal of the disintegrated tissues and physiological rest being the most essential measures.

CASE 3.—Bony ankylosis of right knee joint in a slightly recurvated valgus position; fistulous sinuses about the articulation; numerous cicatrices at the knee and thigh; resection of a wedge-shaped piece of bone; attempted immediate amputation; difficulty of arresting hemorrhage; recovery.

The patient was a native of New Mexico, 28 years old, weighing 240 pounds, of apparently robust and healthy constitution, florid appearance, with occasional pain, but not sufficiently intense to seriously interfere with his well-being. The limb was bent at the knee backwards and outwards. There were numerous funnel-shaped cicatrices, about and above the knee; fistulous openings around the internal condyle of the tibia. One seemed to perforate the head of the fistula. The sound strikes bare bone. There was a discharge of inodorous, watery pus, and complete bony ankylosis of the knee. The thigh was somewhat enlarged, and the structures firm, but not œdematous.

About 2½ years ago, the patient received a bullet wound from a Winchester rifle. The two fistulous openings represented the points of entrance and exit of the ball. The hemorrhage had been profuse, and the wounded man remained several hours on the ground before assistance reached him. The wound was dressed about 30 hours afterwards. Evidently the character of the in-

jury was not fully appreciated, and a fracture of the tibia was ignored. From this time his treatment was limited to incidental symptoms, and no attempt was made to reduce the displaced fragment. Perhaps the very position assigned to the limb, being almost vertically suspended, contributed to the further displacement. Thus new bone was formed, which implicated the articular surfaces, and ankylosis ensued.

In view of the fact that the patient kept a saloon, and was one of his own best customers, it is surprising that he got along as well as he did.

Although his sufferings were moderate at the time when he was taken under treatment by Prof. Bauer, the limb was an objectionable appendage, and the patient came thinking that amputation was his only remedy. However, the promising condition of the constitution led Prof. Bauer to propose excision of a wedge-shaped piece of bone from the knee, with the view of correcting the position and rendering the limb more useful. It was expected that the affected portion of the tibia and fibula would be sufficiently exposed in the operation to permit the removal of all the diseased bone, and placing the parts in the condition of a healthy compound fracture. The patient was delighted with this proposition, and readily gave his consent to the operation.

The operation was performed antiseptically, April 18th, 1887, at the Pius Hospital, Drs. Vaughan, J. L. Bauer, Grayson, Trentler, Cole and Disse assisting. An anterior semilunar flap was made over the knee and the femur was then obliquely divided through the condyle. The condition of the medullary structure of this bone was now found to make the designated plan impracticable. For the medulla was so completely disintegrated as to compel amputation, which was performed through the middle third of the thigh. Even at this point, the medulla was far from being in a normal condition; but the bleeding from the medullary cavity gave hope of recovery, and therefore no amputation at a higher point was deemed necessary. There was great difficulty in securing the ligature of the femoral artery—the only bleeding artery in the wound—whereas the veins bled very freely. It was absolutely impossible to draw the artery out of its sheath. It appeared in a very close organic connection with the surrounding tissues, and it was therefore necessary to isolate the artery with a part of its environment before ligation could be effected. Inasmuch as the entire tissues of the thigh were in a state of sclerosis, the

proximate compression of the artery could not be fully effected; so the patient lost a good deal of blood, and was almost in a state of collapse when he was placed in bed. Another difficulty presented itself in the closing of the wound. In fact, the sclerotic infiltration of the flaps, although they were of ample length, resisted all attempts at approximation, and therefore the wound had to be left open. With the exception of a very slight secondary bleeding, probably from small branches of the profunda femoris, which ceased without interference, the patient made a very satisfactory recovery, and has since returned to his home in complete health.

On inspection of the specimen three objects attract attention:

1. The track of the bullet, which lies between the two points before mentioned. This track is surrounded by disintegrating bone and could have been reached by the intended lower line of the saw. This would have laid it open, and rendered the scooping effective. It should be remarked in this connection, that, although the bullet wound in the bone was mainly in the tibia, the joint was opened thereby, and the cartilage of the femur probably compromised with it.

2. Behind this track the articular end of the tibia has been longitudino-obliquely split off, whilst the anterior part remained uninjured. The fragment, not being properly replaced, it was permitted to slide downwards, backwards and outwards, and in this position it united by callous with the main bone, and osteophytes bridged the articular surfaces, and obliterated the joint. Obviously, the displacement of the fragment led to the mal-position of recurvation and bow-leg.

3. The degeneration of the medullary structure in the lower half of the femur is certainly an unsuspected and rather strange complication. The pre-existing osteomyelitis must have been very violent to cause the degree of medullary disintegration found. So much so, that in the portion of femur amputated, there is not a vestige of the cancellated and reticular structure of the medulla. So far as the specimen serves as a guide, the femur was so insignificantly reached by the passage of the bullet through the tibia, that it is almost impossible to ascribe the osteomyelitis to the main injury. There seemed to have been no outlet to the disintegrated medullary structure, and the serous and purulent infiltration which must have preceded the late condition; and therefore, the patient must have suffered the tortures of Tartarus while the osteomyelitis was in progress. Again, it is almost incomprehensible how

such a condition could have existed in our patient with so little suffering and limited constitutional perturbation.

Prof. Bauer remarked that in a surgical practice of nearly fifty years, with all the diversified cases which had come under his observation as spectator or attending surgeon, he could not recall one approximating in the least degree the present case. Equally surprising is the recovery of the patient, under circumstances so dangerous, so diversified, and so complicated. During the whole treatment, nothing happened to mar the healing of the wound; and, strange to say, the stump is perfectly well formed. Perhaps it should be mentioned that no suppuration ensued. Whether or not the sclerotic condition of the limb accounts for this singular fact, may be suggested as a speculation. The recovery of this man from the operation to his discharge was completed within six weeks.

COMMUNICATIONS.

THE DETAILS OF BERGEON'S METHOD.

BY HENRY SKINNER, M. D., OF PHILADELPHIA.

The apparatus for treating disease by gaseous enemata consists essentially of a carbonic oxide generator, a rubber gas bag, wash bottle, rubber tubing and the rectal tube. The whole outfit can be purchased at so low a figure that it would scarcely pay the physician to attempt to manufacture it. For those who wish to try it, I will give simple directions that may be readily carried out. Procure a wide mouthed bottle or jar of a quart capacity, fit a cork to it, then with a rat-tail file perforate the cork in two places, making the hole large enough to accommodate glass tubing of the size you intend to use. One quarter inch is a good size. Cut one piece of the tube so that it will be long enough to reach from near the bottom of the bottle to an inch and a half above the cork. Then put a second piece of tubing through the other perforation so that it will also stand an inch and a half above the cork, and make it just long enough to protrude on the under side. This completes the wash bottle. Right-angled joints may be made at the upper end of the tubes, but if they are not made by an expert they are very apt to

break. The rough ends of the tubing should be held in the flame of a spirit lamp for a few minutes until they are slightly fused, as this precaution may prevent some severe cuts of the hands. The gas generator is made in precisely the same way, except that the long tube is replaced by a funnel tube which should reach within a half inch of the bottom. Gas bags can be procured already fitted with brass stop cocks. Before making the carbonic oxide, always be careful to expel all the air from the bag. Begin at the large end and tightly roll it toward the stop cock, which should be open. When all the air is out shut it off, and the bag will be flat and free from air. To the short end of the generator attach a piece of rubber tubing, about a foot and a half long. Place in the generator about a quarter of a pound of bicarbonate of soda; then pour slowly into the funnel tube, so as to liberate the gas not too fast, a mixture composed of one part by measure of sulphuric acid to six of water. When sufficient carbonic oxide has been generated to expel all the air in the bottle, attach the free end of the rubber tube to the gas bag, open the stop cock, and gradually fill the bag with the carbonic oxide gas. If the gas is generated too rapidly, there is danger of forcing out the cork, or carrying some of the liquid contents of the bottle over into the gas bag. The rapidity of the disengagement may of course be regulated by the quantity of acid poured through the funnel tube. When the bag is full the tube should be slipped off from the opening to the gas bag, and the stop cock closed. This should be done in the order named. Next, connect the gas bag by a piece of rubber tubing with the long tube of the wash bottle, to which should have previously been added water up to the beginning of the neck, in which is dissolved about fifteen grains of pure crystallized sodium sulphide. If the crystallized salt is not used, the solution will be muddy, and throw down a precipitate. To the end of the short tube of the wash bottle attach another piece of tubing, which for convenience should be about a yard long. At the end of this is placed the rectal tube. Next, open the stop-cock, and force enough carbonic oxide through the apparatus to expel all the air in it, which is done by pressure on the bag. The carbonic oxide decomposes the sodium sulphide into carbonate of sodium and hydrogen sulphide; the sodium carbonate and part of the hydrogen sulphide go in solution, while the excess of hydrogen sulphide along with the carbonic oxide is forced into the bowel. The

above is the simplest form of apparatus that can be constructed. There are several improvements which may be made on it which greatly facilitate treatment. These are a hand-ball aspirator with check valves and a valve at the end of the long tube in the wash bottle to prevent regurgitation, which is apt to occur with the other if the pressure on the bag becomes less than the pressure exerted on the gas by the bowel. With the hand-ball aspirator the gas can be much more gently and easily forced into the rectum, and with much more comfort to the patient. The rectal tube is then lubricated with cosmoline and inserted. Sometimes it does not pass into the rectum readily, and the gas escapes around it. This may be obviated by forcing the gas rapidly for a few seconds, which dilates the bowel, when it may be readily passed through the internal sphincter. The patient should be placed on the side in the recumbent position, and the clothing loosened. At the first treatment as a rule very little gas can be retained, as there will very soon be an uncontrollable desire to force it out. If forced in too rapidly it will cause cramp, but this soon passes off if the injection is stopped a few moments until the gas causing the distension is absorbed. Most patients readily recognize the proper degree of distension, and will say when they have about enough. I have now treated thirty patients, for some months, aggregating considerably over one thousand injections and have never seen any bad results during or following the treatment. There is one thing that may be said in its favor, which is, that if it does no good it causes no harm. Some of these patients have been under treatment for two months continuously. There is no necessity for renewing the sulphuretted water in the wash bottle every day; all that need be done is to freshen it up with sodium sulphide. Once a week is often enough to empty it.

THE ETIOLOGY AND TREATMENT OF FEMALE STERILITY.

BY A. CALKINS, S. B., M. D., BATH, MICHIGAN.

The causes producing, or tending to produce, sterility in the female may be studied under two general heads: first, those existing and operating before the ovum reaches the uterus; and, second, those that affect its life and development subsequently. In the former class would come all malformations both congenital and acquired, all abnormal nervous and vascular factors acting on the

uterine appendages, whether systemic or local: and many of the peculiarities of function resulting from specific or inherited diseases, and especially all pathological states of the ovaries and fallopian tubes.

Under the second head we may study many of the above causes acting indirectly upon the uterus, together with all local diseased conditions of this organ and its surrounding tissues, peritoneal, cellular, and fibrous; its malformations and positions, with any of the particular idiosyncrasies existing in the individual and developed and fostered by surrounding circumstances.

Many of these causes are beyond our reach as gynæcologists, necessarily: yet, happily, a valuable proportion are within the power of our knowledge and skill to remedy. One authority says that twelve per cent. of all cases of sterility are curable. The great "desideratum" is to be able to separate from the whole sum of the cases those that promise not only a probability, but a possibility of cure.

To have a successful issue from the reproductive act, it is essential that the ovary be in an active condition, with no impediment to its progress to the interior of the uterus, and be then received and retained in a soil fit for its growth, after being fertilized by healthy spermatozoa. Often all of these conditions are fulfilled, yet sterility results from some unnatural state of the generative organs producing an untimely expulsion of the ovum or foetus. This is what Dr. Parvin calls "impotentia gestationis," or the inability of completing gestation.

Habits of aborting, whether relating to some fault in dress, living or constitution, or from some peculiarity of surrounding circumstances, and especially if this habit comes from some difficulty existing in the organism of the individual herself, are of the greatest concern to the physician as an abnormality, producing death of the embryo, as such, and of much importance to the life and future comfort of the patient; and, it may be remarked, much more satisfactory as pointing to a favorable prognosis. It is quite important, in any event, to have a full and complete objective and subjective history of such cases.

With a perfectly developed ovary performing all of its functions normally, we expect an ovule to be thrown off, at more or less regular intervals, and for nearly, if not all, the life of the individual. Whether or not nature ordained that each and every germ-cell cast from the ovary should pass to the uterus and there be vitalized, we have no

need to discuss in this connection ; but it is essential that some of them do find the "narrow path" unobstructed and in position. If, however, there exist some unnatural formation, a bound down or misplaced Fallopian extremity and the ovary be not grasped, or if the tube itself be occluded or pouring out a secretion detrimental to the life of the ovum, then permanent sterility would certainly exist. This state of affairs may have been from birth ; but much more frequently is the sequela of perimetritis or general peritonitis, remains of old specific disease, as gonorrhœa in sporting women barren for this reason; from almost every case of puerperal inflammation caused by ptomaines entering the nervous and lymphatic circulation from a recent wound, and even from benign inflammations extending up the tubes and implicating the peritoneum. In fact all lesions effecting the formation of pseudo-membranes, forming cavities, and cul-de sacs dividing regions, making and breaking connecting cords, etc., which later on contract, warp, and destroy the symmetry and original positions of the organs and tissues in their neighborhood, alter the vascular and nerve supply to the uterus and its appendages, and leave the victim utterly unable to fill her place in nature's economy.

It is to the uterus itself that we must look for the greatest obstacles to female fecundity. The spermatozoa can only retain their vitality for a limited time at blood-heat, and in an acid medium, dying soon in the vagina. The life of the germ cell is prolonged in an alkaline menstruum. If now the endometrium under certain conditions of the blood supply be bathed with a neutral or acid secretion, death of one or both of the cells will speedily occur, while under favorable circumstances it is known that both sperm and germ-cells can retain their vitality for from 3 to 7 days. To insure fertility, *there must be a healthy endometrium with its corpuscular layer well developed.* Not hypertrophied and pouring out an abundance of viscid gelatinous mucus, not covered with fungus growths flooding the tissues with fluid blood on the slightest provocation, nor in a state of chronic inflammation or functionally altered by specific and inherited diseases. Any morbid force influencing the formation, nourishment, and growth of the decidua, will be just as detrimental. This is a point to which I wish to invite special notice. It has an intimate connection with the relation that ovulation bears to the periodic act of menstruation, and explains how we may find fecundation occurring between the menstrual

periods, and even when menstruation is entirely absent. It also intimates a rational treatment for those numerous cases of sterility, associated with endocervicitis, metritis and endometritis. Dr. Johnston, of Ky., and Mr. Sutton, of Liverpool, while examining this subject from altogether different standpoints, and with different materials arrived at precisely the same conclusion, concerning the connection of ovulation with menstruation, and the cause of the latter. They agree that menstruation is the result of a glandular function, and that this gland is the endometrium. Before puberty and after the menopause there is but a mere trace of columnar epithelium without any corpuscular development ; while in the menstruating uterus of a woman of twenty there was an abundant corpuscular development, constituting a thick endometrium with its epithelium in the process of casting. Mr. Tait says, in speaking of these facts: "For pregnancy not only is an ovum required, but it is necessary that the ovum when fertilized should pass over the endometrium when it is denuded of its epithelium, and in a condition of turgescence fit for the subsequent process."

One fruitful cause of sterility is hypertrophy and hyperplasia of the uterine muscle, from cervical and perineal lesions. A temporarily big uterus after parturition rapidly assumes its normal weight and dimensions nearly, when there have been no injuries to these soft parts. We may say that permanent subinvolution never occurs without a cervical or perineal laceration. These lesions produce future sterility by increasing and modifying uterine secretions, but indirectly by causing from increased bulk and weight of the organ, and lessened support, flexions versions and prolapses. They also occasion an excessive development of the endometrium, detrimentally changing its functions, and making it unfit for its part in nourishing and perfecting the fragile and dependent ovum. The epithelial layer is changed organically, and clings tenaciously to its support for such a length of time as to further injure the endometrium.

When the hypertrophy is the effect of any obstacle hindering the expulsion of the uterine contents, the organ becomes congested, its contents retained and more or less hardened, irritating its sensitive membrane, and destroying the embryonic decidua. Then when the obstruction is overcome by increased and fatal force it sweeps everything from its interior into the vagina. This obstacle may be a tenacious plug of mucus stenosis of the internal os, a small polypus

or a flexion of the cervix. A lacerated or a conical cervix, and a tense or stenosed os may cause an enlarged uterus by keeping up an increased vascular supply by nervous irritation calling an increased amount of nourishment to the part. They also make an unsurmountable barrier to the passage of the semen from the posterior cul-de-sac into the uterus.

Leucorrhœal discharges from whatever source are a fatal hindrance to the fixing of a fertile ovum within its necessary bed of new decidua by a constant flooding of the interior of the uterus and washing back or out of the germinal cell.

Malpositions of the uterus may interfere with impregnation by causing stenosis of the cervix, if there be a sharp flexion. During menstruation, when the mucus membrane of the inlet is turgescient, it will often take the whole power of the uterine muscle to force outward the accumulated blood-clots, shreds of epithelium, mucus, etc., to counteract and breast the current. Dysmenorrhœa is the signal that notifies us of such a condition.

There may be such a dislocation of the cervix that the external os, instead of lying in the pool of semen, is pushed to one side, or in front of, and practically out of contact with the fertilizing fluid. Lateral misplacements may cause the same thing.

To retroflexion the most disastrous consequences are to be attributed. While antiflexion and the versions are serious matters, they simply waste the germinal material and do not in any way threaten the safety of the mother, if such she may be termed. The retroflexed uterus, however, receives and develops the ovum until the increased bulk of the latter forces the uterus against the sacrum, and so destroys the ovum by pressure, unless nature or the physician rights the position of the uterus. It is a sad fact that a large per cent. of the cases of barrenness can be directly traced to produced abortions. Sterility frequently follows an accidental abortion or miscarriage, but not nearly as often, and the amount of injury done to the membranes and soft parts is comparatively slight. The harm done to the vaginal and uterine tissues by the awkward use of clumsy instruments cannot be well over-estimated. Even when accidental, and under the most careful treatment, they are frequently followed by severe symptoms. Lacerations of the cervix, contusions of the vaginal and uterine tissue, make splendid soils for the production of puerperal diseases, especially when decidua and membranes are retained in incomplete

abortions. Many a life has been sacrificed, all hopes and chances of motherhood ruined, or prolonged pain and discomfort induced, in consequence of abortions and miscarriages occurring during the first year of married life.

Making a prognosis is a difficult and delicate task, and should not be formed until the most useful and systematic examination has been completed, and even then should be well guarded. Especially should extreme care be given before deciding favorably in cases that have never conceived, unless we diagnose misplacements or stenosis. It is of course evident that no amount of medical or surgical skill would justify the physician in promising children when there exists a diseased or misplaced ovary or fallopian tube, or in any way benefit a congenital malformation of any of the uterine appendages. It is possible that an infantile or undeveloped organ may be stimulated to a perfect condition, but hardly probable.

The patients that we have the best possible chances of benefiting are those that have previously conceived, but from injury sustained during labor or abortion have since been sterile. Another class of cases to be considered carefully is that in which we find misplacements followed by hypertrophy, stenosis, etc. Possible success may be experienced where sterility has resulted from peritoneal inflammations and cellulitis. In many patients, success will depend upon the amount of moral and mental stamina they possess. The procreative act in mankind is an entirely animal passion and should be conducted as such. It is none the less a "gift from Heaven," and need not be reduced to brutism, as is frequently the case; neither should it be transacted upon a purely business basis or from entirely politic reasons. The female should be in the best of spirits and health and with a perfect trust (so far as may be) that the fruition of her hopes will be realized. It is a well authenticated fact that mental states have as much influence in procreation as in other acts of animal economy. Fear, anger and shocks have their detrimental effects, as well as pleasure, love and faith their reward. Unqualified license is as much to be condemned as total abstinence, and with about the same result as far as offspring are concerned.

Having thus briefly reviewed some of the most prolific causes of female sterility, and noted a few necessary cautions regarding prognosis, let us examine what means we possess for remedying the evil. As injuries to the cervix are the starting point of the great bulk of female troubles causing sterility,

so they are the ones calling loudest for attention in those cases that have once been pregnant; but cervical lesions are not directly disastrous to pregnancy from mechanical reasons. If there were no sequelæ invariably following this lesion, its hindering power would be very slight indeed. Without a doubt the inherent force of the spermatozoa would be amply sufficient to overcome all the difficulties that an uncomplicated case of laceration would present. The correct interpretation of these injuries with our modern management would make a favorable prognosis nearly certain. Trachelorrhaphy in the great majority of cases is capable of restoring the eroded and everted lips to perfect apposition, thus soothing the reflex nervous phenomena of stomach, heart and nerves. But when we remember that hypertrophy of the whole uterine tissue, muscular and mucous, is a direct result of these lacerations and contusions, and that subinvolution, hyperplasia and puerperal inflammations, are intimately connected with them as cause and effect, and that at least 56 per cent. of all cases of female sterility are due to them, with 40 per cent. to displacements—when we remember these facts, so far as the life of the ovum is concerned, we need only investigate for the purposes of treatment the lining membrane of the uterus, *i. e.*, the endometrium. In other words, if we can cure the existing endometritis, we will at the same time remove, so far as is ever possible, the obstacles to conception.

If this endometritis be due to subinvolution from a lacerated cervix or perineum, trachelorrhaphy or perineorrhaphy should at once be performed, if the condition of the patient does not contra-indicate so trivial an operation. Should involution still be slow in progress, and the other pathological symptoms remain, we will be justified in amputating the cervix high enough up to remove all devitalized tissues. Care must be exercised in this operation that complete occlusion of the external os does not occur from contraction of the cicatrix, or, from the same cause, stenosis. This may be guarded against by leaving in the cervix a short and blunt uterine stem, or a tupela tent, well disinfected and of medium size, about No. 12 English scale.

If the subinvolution date from an incomplete abortion with retained membranes and decidua, no surgical manœuvre will be necessary, unless it be scraping the endometrium with the dull curette to remove the thickened epithelial layer and fungous growths, if any exist. In the majority of cases, painting the

interior of the uterus weekly with strong tincture of iodine, with carbolic acid, will produce a sufficiently alterative and absorbent effect. Involution may be further hastened by continuous hot douching for 30 minutes, by a 1-2000 solution of corrosive sublimate, to the cervix and vaginal vault. Wool tampons, saturated in a solution of alum in glycerine and systematically packed around the cervix, act advantageously as supporting and depleting agents. If much tenderness and pain exists, iodoform sprinkled upon the cervix will relieve it.

Recently, in one case, I used the intra-uterine tampon recommended by Dr. Talliaferro with the best of success, so far as reducing the chronic inflammation and subinvolution were concerned. This method of securing a continuous and equable pressure, when there is no acute inflammation in the periuterine structures contra-indicating it, is a great advance in practice.

Restoring a torn perineum by perineorrhaphy favors the better consummation of the sexual act because the semen is retained until its function is performed, and therefore conception often follows. Whatever influences the laceration had upon the position of the uterus, any malposition of the latter will at the same time be remedied and the chances of fertility increased.

Dilating a stenosed os, or straightening a flexed cervix by rapid or gradual force, opens the channel for a free communication between the sperm and germ cells, and lessens uterine and ovarian engorgement.

Flexions, versions, and prolapses are to be replaced and mechanically retained until nature or a surgical operation secures the uterus in good position. Patience will be required, with considerable skill and ingenuity, when the displacement has resulted from old puerperal inflammations and cellulitis. Suitable pessaries or vaginal and uterine tampons, with local medication, will sometimes cause absorption, stretching, or breaking of the pseudo-membranes, allowing a return of the organs to their original position.

Electricity holds an enviable position as a curative agent in these cases, it having the power of bringing on resolution and absorption second to none. It is a strong tonic, stimulating both secretion and excretion. Under its stimulating action, infantile and under-developed ovaries may be excited to increased growth, their blood supply increased and assimilation improved, until they become competent to perform their required function in the vital cycle. Upon

the uterine muscular fibre it acts as an excitant and tonic. It induces contraction and strengthens the tone, causing absorption of effusions and regulating the circulation. For this reason it has been termed "the only true emmenagogue." In subinvolution and metritis it causes a tonic contraction of the muscular tissues, driving into the circulation and excretions the over-developed tissue cells and migrating leucocytes. In pelvic peritonitis and cellulitis it softens up the indurations and causes their absorption.

Spasmodic dysmenorrhœa is found to be a symptom in two out of five cases of sterility. If this is found to be of reflex origin, the original cause must be discovered and remedied. This cause is usually an irritation of the uterine nerves from a stasis of the blood in the uterine veins, the result of an unequal circulation. Electricity seems to be the one agent that can equalize the vascular supply.

Menorrhagia and metrorrhagia are frequently the cause of "one child" sterility, and can be directly traced to the increased surface of mucous membrane which is frequently diseased by inflammation, villous or glandular degeneration, or from the ulceration of new growths. Still, we must not forget that it may arise from some general systemic cause independent of any morbid condition of the sexual organs. When we conclude that the interior of the uterus contains the tissues at fault, and there be no possibility of hæmatocele, pyosalpinx, extra-uterine pregnancy, or malignant disease of the cervix, dilatation of the neck should be resorted to, and the interior of the womb thoroughly examined, and the appropriate treatment begun. If villous growths are found, they should be scraped off with the curette, and the endometrium painted with iodine or sprinkled with iodoform. The intra-uterine tampon is highly recommended in such conditions. The internal remedies most likely to be of benefit are ergot, nuxvomica, hamamelis, viburnum, and hydrastris.

If the excessive flow is only a symptom of some systemic difficulty, as Bright's disease, general active hyperæmia, or general debility, tonics and special treatment will be indicated. The constitutional treatment to be adopted in these complications following laceration of the cervix, subinvolution, etc., will depend upon the individual peculiarities of each case.

The main idea to be kept before the mind in the treatment of sterility, arising from some injury done the reproductive organs in a previous pregnancy, being to secure a healthy structure and function of the en-

dometrium, and in proportion as we succeed in this endeavor will sterility give place to fertility.

Much more difficult and far less satisfactory is the management of cases that have never conceived. Their etiology is "shrouded in darkness," and their successful treatment is "past finding out." As a rule, primary sterility depends upon some abnormal condition of the ovaries and their nervous connection with the uterus. This may be congenital, or constitutional, or due to inflammations or nervous reflexes.

If amenorrhœa exist, we should interrogate the heart, liver and kidneys for its cause. As menstruation is the safety valve by which the gradually increased blood and nerve tension is relieved, so amenorrhœa is circumstantial evidence that some other loss is taking place in the organism, or that the vital forces are too feeble to afford the expenditure. It may result from absence or imperfect development of the reproductive organs, or of degeneration affecting both ovaries, or the ovarian nerve centres may be in a torpid condition. There may be a partial and temporary arrest of development in the circulatory system and sexual organs, as in chlorosis. There may be mal-nutrition, anæmia and tissue degeneration in renal and hepatic diseases, or there may be excessive waste of nerve and nourishment in organic lung trouble, in which case amenorrhœa would be conservative.

The treatment will be mainly constitutional. Electricity, nerve and heart tonics, wholesome and abundant food and exercise, with special medication for the heart, kidneys, liver and lungs.

Outside of cases needing medical or surgical treatment, we find numerous subjects in whom hygienic laws can be applied advantageously. Just at the close of menstruation, when the endometrium has cast its epithelium, and the soft, velvety tissues are engorged with blood, is the most favorable period for impregnation to occur. This fact has long been recognized and utilized, but not until quite recently has it been theoretically explained. It is well then to advise coition to be practiced at this time, with abstinence between times. Cleanliness, although a delicate prescription to give a confiding patient, will be often a useful one. Have the vagina well flooded with pure or slightly alkaline water an hour or so before intercourse. This will sweeten the vaginal secretions, and remove the tenacious mucus, and thus favor life and motion to the spermatozoa. If there be any dislocation of the

cervix laterally, have the act of insemination take place with the woman upon the side towards which the os points, and have this position kept for a couple of hours. If there be loss of perineal tissue it may insure fertility to have connection take place with the woman's hips elevated, and shoulders and head low, thus favoring the retention of the fertilizing fluid and its passage into the uterus.

To cure certain cases, temperance and regularity must be advised. Sexual excess or over-indulgence keeps the organs over-stimulated and engorged with venous blood, and in a condition similar to subinvolution. It is of course impossible to make any hard and fast rules, but it is safe to say that the sexual desire should not be gratified to such an extent as to leave the parties ænemic, exhausted and unfit for the other duties of life. To have the nervous system capable of acting its part in a fruitful union, it must not be in a condition of perpetual shock.

Artificial impregnation has been practiced by Dr. Marion Sims, Dr. Sinety and others, but not with very flattering results. It is only available where there exists some irremediable obstacle to the passage of the spermatozoa into the uterus.

A CASE OF MORPHINE IDIOSYNCRASY.

BY H. N. BURR, M. D., OF WILLIAMSON, N. Y.

The following case, that came under my care during the summer of 1886, was so full of interest to me that I think it would be of interest to others:

Mrs. M——, aged sixty-five years, had for a number of years past been a sufferer from that painful disease, *tic douloureux*, and, in her desire for relief, she had consulted the most eminent physicians and surgeons, in the hope of finding a remedy that would cure her. The *Materia Medica* had been exhausted, and she was left poorer in pocket, but no better in person. Every physician in the region around had tried his skill to bring relief, and all in vain. She suffered on year after year.

I came into this town and had known her before she was the victim of this disease. I visited her, and in conversation suggested that, to relieve her severe sufferings, she should allow me to use the hypodermic syringe with morphine. She said it had never been used on her, but that she would try it, as she was suffering intense pain at the time. I injected into her arm a tenth of a

grain of morphine, and in a short time she was comfortable, and I went away. About four hours after, I was called in haste to see her, and found her unconscious breathing slow and labored, with a feeble, failing pulse that indicated her near approach to death. It was a great surprise to see such an effect from so small a dose of morphine and in so short a time. Upon inquiry, I learned that after leaving her she had sunk into a quiet slumber for a time, and then passed into a deep heavy sleep from which it was impossible to arouse her. Something must be done or life would soon end. I immediately injected one hundred and twentieth of a grain of atropia and awaited results. The pulse began to improve, but not the breathing, the former continuing very good for an hour or two, when it declined and was almost gone. The same dose of atropia was repeated with a like result, the pulse improving, but not the breathing. I remained during the night and continued to use the atropia at intervals of two or three hours, with varying results. The breathing was very slow, and the intervals between the breaths so long that her friends would say she is gone. I had not been able to get her to swallow anything during the night. I was discouraged and thought she must die in a few hours, and returned to my business for a time, and when I returned expected to find her dead. She continued in this state until the evening of the second day, when she began to improve and woke up, took some food and spoke. She continued to get better, and was able to sit up and was free from her old enemy the remainder of her life, saving a few slight twinges in her face. This was the most remarkable case that had ever come under my observation, and the small dose of morphine had given me much trouble and alarm. Upon inquiry afterwards, I learned that she had had some such a time from taking morphine some years before. After coming out from the influence of the morphine, she had a long sickness of two or three months, in which she was helpless, but was not paralyzed, only prostrated, and when she got up from that, she did not have any return of her old complaint. Something had wrought a change in her disease, and the question naturally comes up, what was it? I think it was the morphine and the severe impression it had made upon her system. I had her under observation nearly a year, and saw her ride out and attend church and social meetings, and her disease did not come back to trouble her.

FOREIGN CORRESPONDENCE.

London Letter.

Sir Joseph Lister found recently that Lister is not so well known as Listerism. He was travelling in Sicily, and at Palermo wished to procure some bichloride of mercury, with which to saturate some blotting-paper to press some plants, the germicide preventing mould. Accordingly, he went into a drug-store and wrote out a prescription for the bichloride. The drug clerk read it carefully and refused to fill it, saying, "I know not the signature." Looking about him, the father of antiseptic surgery saw "Système di Lister" in bold letters calling attention to the large stock of antiseptic wares on hand; for in no other country has Listerism gained more sway than in Italy. Pointing to his name, Mr. Lister told the clerk that he was the founder of this system. "I know not the signature," was the stubborn reply, and Mr. Lister had to go without his antiseptic.

I have just come from Lister's operating theatre at King's College Hospital. He looks a little more grey than when I saw him last, six years ago; but he is still the same pleasant, kind, affable gentleman. The attendance upon his clinic was quite as large as formerly, with a number of foreigners. He does not now use the spray, though some of his followers here in London still use it with a vengeance. In Germany, where the antiseptic craze is so strong, I did not see the spray used at all.

At the operation this afternoon, Mr. Lister removed a breast in a woman where he suspected the presence of scirrhus, but was not sure of his diagnosis. He made an exploratory incision, found it to be scirrhus, and amputated the breast. He spoke strongly in favor of the exploratory incision. In one case, in private practice, he was called to amputate both breasts. The attending physician was sure she had a scirrhus of one breast, and probably of the other. He did not feel certain, and made an exploratory incision. He found a simple, single serous cyst. The same condition was found in the other breast. He dwelt at length on what a fearful calamity it would have been had he removed both these breasts, and then found only a simple cyst. In the operation to-day, the disease was in the early stage, and the question was, should the axillary glands be removed? Careful examination could find no evidence that they were affected. The first one which could be found was removed

and cut open. It was found entirely healthy. He considered, however, that it was to the woman's best interests to have them out, which was accordingly done. Careful examination found one gland at least which was diseased. Mr. Lister related that it was only this morning that he had been consulted by a lady who had her breast removed three months ago for scirrhus. The surgeon thought the glands unaffected and did not remove them. Now they were affected badly in the axilla, and even above the clavicle, and were clearly beyond help. Had they been removed, the case in all probability would have been quite different, as is often proven.

Great Ormond St. Hospital is the oldest special hospital for children in London, and I understand in the world. It was founded by Dr. Charles West in the year 1858. It started out in quite a modest fashion in two old dwelling houses, but has grown until it now treats annually 15,000 sick children. The greater number of these are out-patients. The staff consists of fifteen physicians and surgeons, besides consultants, house surgeons and physicians. They are chosen from the various hospitals of London, and are an able body of men.

The array of cases is somewhat monotonous in the general run; but, among such numbers, there are necessarily many intensely interesting.

It is wonderful what crowds of children are brought here suffering from chronic suppuration. Hip disease, psoas abscess, caries of the spine, inflammation of the joints, and the general manifestations of scrofula are present with fearful frequency. Skin diseases and troubles arising from mal-nutrition and bad hygienic surroundings form the great majority of the walking cases.

Hair-lip is a malformation which demands much time and consideration. The operation has been so often performed that the acquired experience proves of great value to the operators. One of the most successful operators in London is Mr. Thomas Smith, surgeon to St. Bartholomew's Hospital. Mr. Smith is now consulting surgeon to the Hospital for Sick Children, but was on the active staff in 1881, when your correspondent was serving as clinical assistant there. It was then my privilege to see him perform this operation a number of times.

By way of a slight digression, Mr. Lawson Tait, before a recent meeting of the British Gynecological Society, in a paper on his method of flap splitting with the flange suture, in vesico vaginal fistula and perineal

operations, said he would recommend its trial also in cleft palate.

Mr. Howard Marsh, surgeon to the hospital, has made several operations in the last few weeks for cleft palate. His results were very good in all cases but one, in which the child coughed considerably after the operation, and the flaps failed to unite in the soft palate, although doing so in the hard. He thought the soft palate would heal to a great extent by granulations. Mr. Marsh does not recommend operating for cleft palate before the child has reached four or five years.

He warned his listeners not to go too far back with the operating knife, as there is danger of wounding the posterior palatine artery. If the artery is cut, it retracts up the canal, and there is no chance to get at it to ligate or use pressure. He had this to occur in two patients under his care in St. Bartholomew's; one of them bled very much and long. He finally stopped it by finding the posterior palatine canal and pushing up into it a match wrapped with cotton. This was also done in the other case, but, the plug coming out, the nurses could not return it, and the patient bled to death. The opening of the canal can be found just by the last molar.

Dr. Robert J. Lee, of Gt. Ormond Street Children's Hospital, has recently brought out a very practicable, simple and useful instrument, which he has christened the "Fumifyor." Its use is for the inhalation of the vaporous medicinal agents. By means of this instrument combustion can be carried on, in their pure state, of such substances as stramonium, lobelia, belladonna, opium, digitalis, conium, coca, Himrod's powder, and other substances, without the addition of nitre or other combustible material. With this the smoke of the vapor of these substances can be easily inhaled, and their therapeutic effects obtained for the relief of various pulmonary affections, such as asthma, bronchitis, and whooping-cough. The Fumifyer consists of a spirit lamp, over which is a reservoir of water, which, on becoming heated, passes a current of steam out through a pipe, not unlike a sprinkling can. On this pipe and connected with its cavity is an upright part, which contains the medicine to be fumified. This makes it resemble a tobacco pipe and the process much like smoking. The steam causes the suction, and the smoke from the burning medicine (or tobacco) passes down out of the pipe and into the patient's mouth, which is at the extremity. The draught can be regulated by moving a simple slide, which also controls

the rate of combustion. The fumifyer may also be used as a simple inhaler. The Floral Fumifyer, used in green-houses for fumigating plants, is constructed on much the same principles.

The medical profession hinted long and loud, through both the medical and secular press, that the queen should commemorate the jubilee by the appointment of some medical man to the peerage, an honor never yet bestowed on medicine in England. The hint, however, was not taken.

We have recently had "Hospital Sunday," a thoroughly English institution. Last year the amount raised in London was 40,000 pounds, and it is hoped more will be realized this year.

Dr. Norman Moore, pathologist to St. Bartholomew's Hospital, finds that the great majority of deaths of patients suffering from gout which occur in the hospital, and a great number do occur there, is caused by vascular degeneration. A few die from acute disease, but only a few. He says we must remember that a gouty person is not only a man with a pain in his great toe, but that he probably has acute nephritis accompanied by dilatation of the left ventricle, and probably vascular degeneration and atheroma. Aneurism was seldom the cause of death. He had only known of one case, the specimen of which he showed us. He exhibited a number of specimens from a man who had been examined after death during the past week. Urate of soda was visible on the great toe and patella, of the right side. None was met with in the tarsal bones. On the left side it was found in the great and second toe, in the astragalus and every bone of the tarsus in abundance. None in the ankles. No gouty deposits in the ear. This urate of soda is only found where degeneration has taken place. It is not deposited till this has taken place. Gouty parts are often said to contain pus. If examined under the microscope this will be found not to be pus but the urate of soda mixed with the synovial fluids, thus giving it the resemblance of pus. The size of the kidneys was in this case very little reduced. On examination the pelvis are found full of fat and the true kidney substance reduced. The subject has also emphysematous vesicles in his lungs.

Dr. Matthew Duncan, in lecturing to his students, recommended them to have lots of cotton by them on the occasion of a premature birth. The child should not be washed, the skin is too soft and tender. If any great amount of filth is present let it be gently sponged off, then wrap up the baby in cotton.

Of greatest importance is the temperature. This should be taken in the rectum. Though an adult fetus generally has some sub-normal temperature, yet in a premature birth a temperature much subnormal is a cause of alarm. This should be kept up to the normal by all means. The child should be kept in a temperature of 90°. This is best done in what is known as a nest. That of Tarnier, or some of its modifications, being the best. After some time the child can be removed from the nest, and if the temperature remains up to the normal it can be left out, otherwise it must be returned.

Feeding, a matter of the greatest importance, is generally very poorly carried out. Undoubtedly the best thing is the mother's milk. You must get a nurse to sit beside the child, draw the milk out of her breast and give it to the child. Some premature children suck well, most of them do not. It needs a very little food the first few days, a few teaspoonfuls being enough.

In discussing premature labor, Dr. Duncan said that the characteristic case for the induction of premature labor is the flat pelvis. As the method of induction, he recommended the plan of Kiwisch to be of first importance. It is by vaginal injections. This probably involves dilatation and relaxation of the vagina and probably of the cervix uteri. The woman injects warm water, some use cold, some alternate warm and cold. This may be carried on through one or two days, and done five or six times. Care should be taken not to inject into the uterus. He recommended the operation because it was a good preparation for delivery, relaxing and expanding the vagina and probably the cervix. This plan does not generally succeed, but even then you are a great gainer, for it prepares the way for labor. It is the best method when it succeeds. The next best mode is to introduce a tangled tent into the cervix. It should be carried in by the forceps, and should be rendered aseptic as well as the sponge which follows it. This should be done by salicylic acid 1 part, glycerine 5 parts. Labor begins generally in from 12 to 24 hours. Sponge tents and Barnes' bags have no advantage over the simple methods named. If in a hurry he recommended the use of the bougie, a solid one to be passed up between the uterine wall and the membranes. Avoid puncturing the membranes and going between the placenta and the uterine wall. If after inserting it moves freely backwards and forwards it has gone into the uterine cavity and not curled up in the cervix, as is sometimes the case.

This plan sometimes fails. None of them are sure. You should not expect to do a premature labor at a certain hour as you would a lithotomy or an ovariectomy, as claimed by a prominent accoucheur, but be content to wait.

The position of the foetal heart is not considered by Dr. Duncan as a diagnostic sign of breech presentation. He considers the heart to be situated at about the middle of the fetus, not of the child, and is very little, probably no higher in the breech, than in the vertex presentation.

London medical hospitality is commensurate with the size of the city. Those of us who attended the International Medical Congress in 1881, remember with pleasure how right royally we were entertained. High officials, the nobility, corporations, institutions, and especially the members of the medical profession, welcomed us with open doors. It is to be hoped that the Americans will return in 1887 the hospitality accorded them in 1881.

Nor is this British medical hospitality spasmodic. Only within the last three months there have been three medical social events of considerable general interest. First, Mr. W. S. Savory, President of the Royal College of Surgeons, gave a *conversazione* at the college. Music, an elegant repast, the most valuable museums and numerous works of art, furnished entertainment for the evening. Next followed the jubilee dinner given by the Society of Apothecaries. The medical social season was closed on the evening of the 29th of June by a *conversazione* at the Royal College of Physicians given by the president, Sir William Jenner, who is now president for the fourth time. The company in attendance was a large one and the evening was spent very pleasantly. Music by the Coldstream Guards needs no praise from me. Numerous paintings, some of them quite old, many having more or less interest to the medical man formed an interesting feature. Microscopical specimens and culture processes were exhibited in abundance. Microscopes and apparatus of rarity and costliness were there for examination.

Sir Dyce Duckworth, whose visit to America about eight years ago is remembered by many, is the efficient treasurer of the college. *London, July 1st, 1887.*

—More deaths occur from lockjaw on Long Island, it is stated, than upon any other corresponding area of territory in this country.

LETTER FROM LEIPZIG.

TO THE MED. AND SURG. REPORTER :

It has been possible for me within the past week, in accordance with the sole object of my visit to Germany, to see a large amount of gynecological work in the hands of some of the best workers in the world.

In my more extended gynecological tour of last year, I was very forcibly impressed with one idea, which is now becoming a conviction, that is, that only "seeing is believing;" I mean that no amount of home-reading or home digestion of foreign work, will give the ready, correct apprehension of facts one obtains in the few minutes of conversation, or looking on at an operation.

I thought before my first visit to Europe that having an acquaintance with English, French and German literature, I had also a fairly exact estimate of the relative positions of the three countries, their teachers and laborers in scientific medicine. Such, however, was not the case, and I found myself in many instances very seriously in error, and obliged to reconstruct my standard, and even, to my sincere gratification, to place *home-work relatively very high*. American surgeons need come abroad with no feelings of deprecation, and in no apologetic mood, for although we have a vast deal to learn from others they in turn can take many lessons of us. A query which is often put is, "What will be the gynecology of the future?" I answer for myself (pardon the bull) that the gynecology of the future, which practically concerns us, *now exists*, and it is this, that "that which is *best* and *peculiar* in each nation should as quickly as possible be made common property."

When we consider the great number of distinguished gynecologists to be found throughout the length and breadth of Germany it is remarkable what centres of activity are to be found in the various towns. I have now been in Leipzig eight days, and constantly in the society of Dr. Sanger, who is especially well known to us as one of the foremost men of the age, having literally dug up the old operation of Cæsarean section out of a very deep grave, and showed so exactly wherein the conditions of success lay that it is now a *safe operation*, under many circumstances to be preferred to craniotomy; he has thus saved a great number of women from the serious mutilation of Porro's total ablation of the uterus.

Dr. Sanger performed two very interesting laparotomies on the very morning of my arrival; removing in one case a small paro-

varian cyst from the right side, and a curious small multiple dermoid cyst of the left ovary. The other case was a retention-cyst of the gall-bladder, which was first stitched to the abdominal wall, and opened after six days by the cautery, when it discharged about 8 ounces of a dark viscous fluid. Both cases have run their course without fever or pulse elevation. An interesting case of hysterectomy was performed yesterday morning in his private hospital (called *klinik*). A large fibroid tumor had choked the pelvis, even causing a prolapse of the uterus with the anterior vaginal wall. On account of this complication, after having cut away the tumor with ovaries and tubes, the stump was brought outside at the lower angle of the wound, transfixed by two large sail-cloth needles.

The peritoneum was sewed carefully to the stump just below the elastic ligature embracing it, and a dressing of iodoform and tannic acid, in equal parts carefully applied.

Prof. Cr  d  , so long celebrated for his studies of the puerperal state, has retired altogether from medical duties and lives quietly in the best quarter of the town.

His successor in the Lying-in institution is Prof. Zweifel, from Erlangen, who is ably assisted in his duties there by Dr. D  derlein. The work which Dr. D  derlein performed in his investigation of cysts of the hymen is well known, and I can testify from observation that his handling of his microscope and mounting of long series of specimens cut consecutively from the finest, smallest pieces of soft tissue, is something wonderful. At a meeting of the Leipzig Gynecological Society I had the pleasure of meeting Prof. Hennig, long known to me by reputation, more particularly as the author of the pamphlet on retention cysts of the Fallopian tubes.

Dr. Becker-Laurich, medicinalrath, of Altenburg, was also there. Dr. B. Laurich is not so well known to us in America, but he is noted here for his practical genius in midwifery. From him came the celebrated Altenburger pelvis described by Fehling in the Archives for Gynecology; he also furnished the uterine lithop  dion described by Prof. Hennig.

I had the satisfaction yesterday of seeing my operation of Hysterorrhaphy performed by Prof. Zweifel.

A large heavy fundus which lay retroflexed in Douglass' pouch was raised and sutured just below the cornua to the anterior abdominal wall. I know of other cases here in which sufficient time has elapsed to say that they have all been successful, and the method

promises to have a wide field of usefulness. It is called here the Kelly-Olshausen method.

I hear many complaints here about the heat, but the weather is very much such as we hope to find in our mountain resorts, and the fact that it is summer need deter no one from our side of the water from Germany.

Very truly, HOWARD A. KELLY.

HOSPITAL NOTES.

PHILADELPHIA INFIRMARY FOR NERVOUS DISEASES.

A CASE OF PSEUDO-HYDROPHOBIA.

Service of DR. OSLER. Reported by DR. BURR.

B. D., aged 25, always healthy, and never has had any nervous trouble. When about ten years old a dog bit him slightly on the upper lip. The wound soon healed and he thought nothing of it. Eighteen months ago he was bitten slightly on the right thumb. Two months later the thumb began to pain, which scared him and made him nervous, but it soon passed away. A few weeks ago one of his fellow-clerks told a story of a man who died of hydrophobia years after he had been bitten. This story influenced the pa-

tient very badly. He became nervous, the pain in the thumb grew worse; the dread of hydrophobia pursued him constantly; sleeplessness came on, and finally his condition grew so bad that on the ninth of July he was compelled to quit work. At that time Dr. Osler saw him, assured him that there could be no possible danger, and prescribed a nerve tonic for him. In a few days he returned complaining of nervous chills, trembling of the limbs, great restlessness and sleeplessness, and stiffness of the jaws and neck. He had a spasm of the throat, and imagined he could not swallow water, but after a great effort he did swallow a mouthful. The next day he was better, and could drink water easily. He still, however, was intensely restless, pale, with dark rings around the eyes, and indeed looked very ill. He still complained of the stiffness of the neck, and the irritation and soreness about the thumb. There is no scar in the sore spot. He was ordered potassium bromide gr. xxx every five hours until he could sleep. The next day he was much better. He was ordered Faradism to the neck and spine. He returned in a few days practically cured. A few weeks ago the dog was still alive.

EDITORIAL DEPARTMENT.

PERISCOPE.

Trophic Nerves.

The actual demonstration of the existence of trophic nerve fibres, apart from vaso-motor fibres, has not until recently been made, although many evidences pointing to that conclusion have been put forward. Dr. Joseph, of Berlin, in a number of experiments on cats, produces facts which go to prove the existence of trophic nerve fibres in the peripheral nerves. The complication of vascular changes induced by the removal of the vaso-motor fibres from a part must be excluded in order to prove definitely that any nutritive changes occurring after section of its nerve are due to the loss of trophic influence. These conditions were carefully considered, and in order to avoid any vaso-motor changes, the second cervical nerve was selected for section, which, as will be seen, contains no vaso motor fibres. This nerve was used in all the experiments. Mere section of the trunk of the nerve produced no effect, as reunion rapidly took place, so that it became necessary to remove a considerable portion of the trunk to prevent this occurrence. In some of the ani-

mals the ganglion on the posterior nerve-root was also removed. The changes induced were limited to the area of distribution of the nerve, and in those where the ganglion was removed similar changes occurred in the cutaneous area of distribution of the fifth cranial nerve of the corresponding side, coming on in different animals at a period varying from five to twenty-seven days. The changes consisted in loss of hair, at first localized, afterwards gradually extending, situated above and behind the ear where the trunk was only severed; above the eye and over the cheek, where part of the trunk and the ganglion on the posterior root were removed. After a time complete baldness and a shiny atrophied state of the skin made their appearance. No increased vascularity, inflammation, or any other change whatsoever could be discovered in the skin. The hair was examined for parasites, but none could be found. Microscopic examination of the skin failed to detect anything beyond atrophy of the hair follicles; there was no evidence of inflammatory or other changes. From these experiments Dr. Joseph concludes that trophic nerve fibres exist apart from vaso-motor

fibres, and entirely independent of them; and he explains the similar changes in the area of distribution of the fifth cranial nerve by assuming that it derives its trophic supply from the ganglion on the posterior root of the second cervical nerve from which fibres join the ascending root of the fifth.—*Virchow's Archiv*, Bd. cvii, Hft. 1.—*The Practitioner*, July, 1887.

Unilateral Iodism.

In the *British Med. Jour.* for July 16th, Mr. Rice reports an interesting case of unilateral iodism occurring in an elderly, plethoric gentleman of congestive tendencies. The patient is thought to have suffered previously from delirium tremens, or some mental derangement. While under treatment for bronchitis, and after taking three-grain doses of iodide of potash for thirty-six hours, he became very restless, sleepless and nervous, with great fear of impending dissolution. On the next day there was great congestion of the vessels, especially at the right side of the head, with considerable cedema of the loose tissues about the eye, side of the neck and ear, the latter being so much inflamed that leeches were applied. The other usual symptoms of iodism, such as running at the eye and nose, and frontal headache, were present, but were all most marked upon the right side. The author thinks that iodine has an affinity for certain nerve-centers, and sometimes attacks in particular one side of the brain.

On Injections of Yeast.

In the *Centralblatt f. d. med. Wissensch.*, of June 18, Falk reports some experiments upon the intravenous and other injections of fresh beer yeast into rabbits and dogs. He finds that no special symptoms follow these injections, and attributes the symptoms of septicæmia obtained by Popoff in his experiments to bacteria in the materials used. Falk then made simultaneous injections into the belly, of cane sugar and yeast, and could find no sugar in the urine. Grape sugar gave the same result. It was possible, therefore, that the fermenting power of the yeast was excited in the living body, and it became especially interesting to test the action of the yeast in animals in whom diabetes had been artificially produced. Artificial glycosuria was in some cases produced by puncturing the floor of the fourth ventricle, in some by electrical stimulation of the central ends of the vagus in the neck, and in some by medicines; the yeast having been previously injected. Setting aside several cases in which the experiments were unfortu-

nate through early death of the animals, it was found that no glycosuria followed in two cases which had been punctured, and also in two cases in which there had been electrical stimulation of the ends of the vagus. In the same way, of the subcutaneous administration of Amyl Nitrite in rabbits, and of ortho-nitrophenylpropionic acid in dogs, diabetes was not obtained, or but a trace of it.

Hyperperostosis Subungualis.

There is a curious disease of the nails—usually of the finger-nails—characterised by more or less deformity of the nail in front of the lunula, and the presence of soft, crumbly substance between the nail and its bed. At times the nail is slightly elevated by this gray or greenish-black mass. This is hyperperostosis. The younger Hebra was successful in curing a case reported in a recent paper, by the use of the Paquelin cautery. He burned away the mass, and the nail, in a series of eighteen sittings. Then the nail grew in a healthy way, and remained sound up to the time of his reporting the case, more than a year.

[Other measures, less severe, may prove useful in this curious disorder. Persistent inunctions with equal parts of mercurial ointment and lard, or thorough soaking with a weak (1 : 5,000) corrosive sublimate lotion and regular scraping of the nail has succeeded admirably in our personal experience.—EDS. OF THE REPORTER.]

The Mechanical Treatment of Skin Diseases.

In the treatment of acne vulgaris, acne rosacea, chronic sycosis, trichophytina barbæ with nodular lesions, and lupus erythematosus, Rosenthal recommends multiple scarifications followed by massage. The scarifications should be made in all directions, and with a small, fine, sharp scalpel. After the bleeding following the scarifications, has ceased, he strokes the part in a centripetal direction for five or ten minutes, using one or two fingers, or a piece of dry lint. Then the part is washed and left uncovered. Rosenthal thinks that he has produced better results with this method than with the parallel incisions commonly employed alone.

Laparotomy.

At a recent meeting of the Imperial Society of Physicians of Vienna, Dr. von Hacker, assistant to Prof. Billroth, showed a woman, aged 38, on whom he had performed laparotomy two years ago, owing to grave disturbances of the stomach, great emaciation, and the pressure of a tumor in

the region of the stomach. Carcinoma of the pylorus had been diagnosed. After abdominal section, the operator found that the tumor was formed by strong adhesions and by an infiltrated bunch of glands which was situated near the pancreas. For this reason he desisted from further operation, sutured the abdominal walls, and the patient made a speedy recovery. The interesting feature of this case was that the patient felt much better since the operation, though the stomach troubles had not entirely disappeared. In the meantime she was delivered of a child, and while she was gravid all disturbances of digestion disappeared. The bodily weight of the patient had, since the time of operation, increased one-half. The tumor in the region of the stomach could not be felt any longer, except as an increase of resistance at that spot. There could certainly be no question of carcinoma in this case. The tumor might have been caused (as in the case which Dr. Salzer had recently shown to the Society) by an ulcer of the stomach with cicatricial callosity. Dr. von Hacker had observed two other cases of this category in which stenosis of the opening of the stomach had been caused by such adhesions, the stenosis being even greater than that produced by narrowing of the opening itself.

Dr. Teleky inquired if the gastric juice had been examined for the presence of free hydrochloric acid, as many authors had stated that in cases of carcinoma of the stomach free muriatic acid was absent.

Dr. Von Hacker replied that he did not remember whether this had been done in the case under consideration, but that such an examination was usually made at Prof. Billroth's clinic.

Prof. von Bamberger remarked that the opinion that free hydrochloric acid was absent in cases of carcinoma of the stomach was not correct. Van der Velden had shown that it was always present.—*Med. Press and Circular*, July 6, 1887.

Hysterical Angina Pectoris.

Allied to genuine angina, due to cardiac ischæmia, are quite a number of pseudo-anginal complaints, attributable, some to gastric dyspepsia, others to a well-marked nervous disorganization. The latter class furnished M. le Clerc with a subject for his thesis. The first case of the kind was recorded in 1812 by Millet, but many more have since been observed by Bertrand, Bal-four and others. The affection in this form is met with principally, but not exclusively, in women, generally before middle age. It

occurs more rarely at the menopause and in children. The attacks are longer, more frequent and more severe than in angina of organic origin. They are remarkable by their onset, which is sometimes central, sometimes peripheral. The differential diagnosis is based on the nature and the seat of the pain, and the presence of some sort of aura, by the multiplicity and the variability of the irradiations, which are more eccentric and present a greater range. The attacks are often more or less periodical; they occur oftener by night than by day, and are provoked by psychical impressions (emotion, dreams, etc.), seldom or never by a physical effort of any kind. Their termination is marked by phenomena characteristically hysterical in their nature. The past history of the patient is necessarily of importance. The prognosis is favorable, both as regards the termination of the attack and the cure of the disease.—*London Med. Record*.

Cocaine in Tonsilitis.

Bœckel has recommended the application of strong solutions of cocaine to inflamed tonsils. He used a ten per cent. solution, applying it at intervals of fifteen minutes. The pain disappeared like magic after the third application, and the anæsthesia lasted an hour. The drug, however, caused a temporary paralysis of the muscles of the soft palate, so that when he attempted to drink, the liquid immediately escaped from the nose. After five hours the abscess ruptured spontaneously, two days earlier than in his previous experience. He recommends the application of a solution (five to ten per cent.) of cocaine at the beginning of an attack of tonsilitis.—*Rev. mens. de Laryngologie, d'Otologie et de Rhinologie*, July 1st, 1887.

Covering Wounds With Plaster.

At an inquest held in the Southwark Coroner's Court last Friday a point was brought out which is of some importance as bearing on the treatment of recent wounds. A school-boy running out of the school-gates fell and cut his forehead. The wound was strapped with plaster, and everything appears to have gone well for four days. Then shivering came on, and was followed by drowsiness deepening into insensibility, and death resulted two days later. After a post-mortem examination, it was decided that the fatal issue was due to blood poisoning brought on by neglecting to cleanse and dress the wound, the plaster never having been removed from the time of its application. In commenting on cases of this kind one naturally allows somewhat for the possi-

ble effects of shock occasioned by the primary injury, which, without amounting to any gross lesion, might yet materially influence the final result. Be this as it may, however, enough has been shown in evidence to enable the coroner to assign to the death in question a more direct connection with the wound itself. The practice of plastering over recent cuts is very usual; it is also one which in numerous instances has proved injurious. Apart from any question of blood-poisoning, indeed, the mere tension of retained discharges is an inevitable source of mischief where this custom is adhered to. The simple rule in surgery which provides for the free escape of pus where such is likely to form is one of which we need not remind any qualified practitioner. Accidents due to neglect of this rule are chiefly liable to occur when a wound has been treated either by the injured person himself or by a practicing chemist. In such cases plaster is the first resource, and is apt to be used rather well than wisely.—*The Lancet*, June 4, 1887.

The Treatment of Chronic Heart-Disease by Baths.

Dr. Gathhold Scholz, of Cudowa, in a lecture upon the treatment of chronic heart-disease, comes to the following conclusions: 1—The patient with heart-disease in the choice of a bath, must be considered with regard to his constitutional anomalies, and have the diseases of other organs accurately examined and acted upon. 2—In the second place, the kind of heart-disease is to be grasped and considered in reference to the method employed for cure. Every bath which acts favorably against a disease of the whole organism, will exercise a healing influence upon the heart. 3—All kinds of baths at a temperature which does not affect pulse and respiration; natural spring water baths, sulphur baths, and also Carlstad baths, become indirectly heart remedies, through the removing of the evil influences which secretions and diseases of the organs exercise upon the heart. 4—Salt and chalybeate baths, and those rich in carbonic acid, act directly, in addition to their indirect action, as heart remedies; and it is to these, therefore, that the first place as cardiac remedies before all other baths is to be given. 5—These same baths are a tonic to the heart of the first rank, and surpass in strength and persistency the action of all pharmaceutical measures. 6—As trustworthy and strong adjuvants, though not of like power with those just mentioned, stand gymnastics, adapted to the heart of each individual case. These, when employed

simultaneously, increase and expedite the action of the baths. 7—These baths and gymnastics, selected rationally, and with regard to individual requirements, and employed after a method that can be constantly and accurately controlled, can never hurt even a severe case of heart-disease; nay, the baths almost of themselves bring the patient to recovery, or conduct him in some cases so far toward it that then, by methodical mountain climbing, and if necessary because of existing obesity, by diminution of food and drink, the perfection of recovery may be attempted, and possibly attained.—*Deutsche Medizinal-Zeitung*, June 13, 1887.

Cleansing the Hands.

Upon this subject, Dr. M. Vogel, of Eisleben, writes that he has noticed that copper-smiths, tinsmiths, etc., whose hands become covered with a dirt from working in oxides and acids, that cannot be removed by ordinary means, first rub their hands with warm oil, and when this has thoroughly penetrated, rub them with powdered borax. Subsequent washing with soap and water makes the hands perfectly clean. He advises those who have to use carbolic acid to go through the process above described first, and claims that in this way (1) disinfection is more thorough; (2) the hands are made purer than it is possible to make them by soap alone; (3) the hands remain soft and free from troublesome, rough epidermic scales, and the odor of carbolic acid is destroyed; (4) the uncomfortable anæsthesia of the hands is avoided after washing with carbolic acid.—*Allgemeine med. Central-Zeitung*, May 25, 1887.

Upon the Ætiology of Acute Articular Rheumatism.

In the *Deutsche Medizinal-Zeitung*, of July 11, 1887, Dr. E. Quenstedt has the following review of the work of the Tübingen Polyclinic. In this clinic, there presented themselves in the space of eleven and a half years, two hundred and twenty-eight cases of acute articular rheumatism. In proportion to the whole number of admission in this time, 22,977, articular rheumatism contributed nearly one per cent. (exactly the same as Typhus). Of the 228 cases of rheumatism, 176 are first attacks, 52 are subsequent attacks. The men furnish 56 (58 per cent.), the women 43 (42 per cent.). The age fluctuated between 2½ and 72 years. The period of greatest frequency is from 15 to 20, with 19 (30 per cent. of the whole number of cases); then next the period up to 14 years, with 18 per cent.; and the third,

between 30 and 40. After 60 years, there are the fewest cases, 5.7 per cent. In winter (December, January and February) 31 cases (14 per cent.) came to the hospital; in spring, 28 (94 per cent.); in summer, 23 (64 per cent.); in autumn, 16 (28 per cent.). Articular rheumatism in winter is benign in its spreading. There is in Tübingen from winter to spring a steady diminution of the number of sick. No positive connection was found between the degree of temperature and the frequency of rheumatism. The relative dryness of the ground and slight rain fall furthered the spread of articular rheumatism, in a manner analogous to that recognized in Tübingen with reference to pneumonia. This peculiarity permits an organized poison to be supposed as the cause of the disease the continued existence of which is influenced by external circumstances. This hypothesis is supported by the observation of the polyclinic, that articular rheumatism is determined in groups—slight epidemics. Eight such groups were noted in Tübingen, two with seventeen and twelve cases; the remaining six of from six to twelve cases. In the parish of Lustnau, containing about sixteen hundred inhabitants, a village belonging to Tübingen, three groups, with twelve, ten and eight cases, were observed. These groups, or small epidemics, show a character of differing severity.

In 1882, an epidemic occurred with seventeen cases of a very infectious nature. Few survived, most of them dying of ulcerative endocarditis. The author has also raised the question whether rheumatism in its spreading is tied to a definite locality. This question can scarcely be answered affirmatively upon the ground of numerous examples. Nearly twofold more persons have a relapse if they stay in the same house, than would have had it if they had removed away.

Treatment of Alopecia Areata.

Schachmann reports ("Ann. de Derm. et de Syph.") twenty-nine cases treated by him with blisters. His method is as follows: A blister as large as the bald spot is applied upon the patch and left on until bullæ form, and then it is removed and the blister is dressed. When the skin is dry (usually on the third day) a new blister is applied, and so on up to three, six, or even ten blisters. The rest of the head is rubbed morning and night with a mixture of oil of turpentine 20 parts, ammonia-water 5 parts, and water 100 parts. If there is only one moderate-sized patch, or a few small ones, blisters are applied to the whole at once. But if the patch is very

large, or if the whole scalp is affected, the head is divided into districts, and these are treated successively. The hair is shaved from about the patches. The duration of his treatment was never more than three months, and generally less than two. In no case were the blisters followed by erysipelas or other complications.

On Temperature in a single Epileptic Convulsion, and in a Series of Epileptic Convulsions.

In the *Centrallblatt, f. d. med. Wissensch.* of June 4, 1887, Bourneville's conclusions in regard to temperature in epileptic convulsions are thus stated:

1. In sixty cases of epilepsy, the rectal temperature in the height of the paroxysm, one-quarter of an hour after, and two hours after the paroxysm, showed an elevation, in each separate epileptic convulsion, of five to six degrees centigrade.

2. The temperature in epileptics in whom the paroxysms accumulated (from two to seven) so that the epileptic state was formed, but yet consciousness returned after each convulsion, showed the same result as after each isolated epileptic convulsion.

Alterations of the Skin in Scarlatina.

Dr. Mandelstamm, of Kazan, has examined by the microscope numerous specimens taken from the skin of the cadavers of eight children, who had died in the course of scarlatina, some of collapse, some of intercurrent diphtheria, some of nephritis, etc. He draws the following conclusions: "1. Contrary to the opinion of Thomas and Bohn, the skin in scarlatina undergoes some important modifications and profound morbid lesions.

2. The pathological process is inflammatory in its nature, affecting at once the corneous layer, the mucous layer, the papillary layer and the connective tissues. It manifests itself by a hyperemia of greater or less intensity, accompanied in these typical cases by oedema of the connective tissue and infiltration of lymphoid elements.

3. The sudoriparous glands are not spared, the limiting membrane is thickened, the epithelium of the tube destroyed, beginning to obstruct by its debris the lumen of the tube, the circumglandular tissue is plentifully infiltrated with leucocytes.

4. In no case has it been possible to discover the *verticillium candelabrum* announced by Tschamer, nor any other species of micro-organism."—*L'Union Médicale du Canada*, July, 1877.

A Preservative for Cadavers.

Professor Bruchard, at a meeting of the Academy of Medicine, of Paris, read a note upon the preservation of cadavers by an injection, of which the following is the formula :

R Hydrated borate of soda... 10 parts.
Glycerini (sp. gr., 30° Baumé) 17 “

Reduce the above to a very fine powder, then put it in a basin and pour in the glycerine little by little to make a complete mixture, which must be warmed up to 80° c. Then put in a sufficient quantity of alcohol to make this mixture fluid. M. Bruchard states that since he has employed this mixture at Bordeaux no dissecting wound has proved dangerous. The students have never presented those gastro-intestinal symptoms ordinarily so frequent in dissecting rooms.—*Le Concours Médical*, June 11, 1887.

Pareirin, a New Tonic Medicine.

As early as 1838, Ezeichel produced from the bark of the Pao-Pareira tree, an alkaloid to which he applied the name Pareirin. This alkaloid, according to the author's investigations, has shown tonic and antifebrile properties. It is very slightly soluble in water, but very freely soluble in ether. The author has obtained success from its use in obstinate malarial cases, which had not improved under any of the cinchona preparations. The largest dose he gives is about two grammes. He believes it to be an excellent substitute for quinine.—SOLEIRO., *Journ. de Médecine de Paris*, No. 23, 1887.

Benign Tabes.

At a meeting of the Biological Society of Paris, Brown-Séquard said: It is recognized to-day that, in certain cases, stretching of the sciatic nerve caused a disappearance of tabetic symptoms. This fact confirmed, in his mind, what he had before maintained, that lesions of ataxia, just as cerebral and medullary lesions, limit their effects not to destruction of the cord, but to an action at a distance upon healthy parts, by a dynamic influence. Later on he remarked that Stokes, of Dublin, had been the first to utilize this fact. The theoretical part of this idea is that when one wishes to attack any morbid state, by actual cautery or otherwise, the better seat of application for the irritant agent is the skin of the lower extremities,

and not the back. It is understood that in so acting upon an extended surface, there is an extremely powerful action upon the cord. Brown-Séquard has developed this theory a little further, and even in 1861, in London, thought of applying circular blisters in epilepsy. He has often obtained excellent results from this procedure. More recently, one of his students has established the fact that, by applying blisters in hysterical anæsthesia, this anæsthesia disappeared from the affected side and went to the other; and, if attacked there, disappeared finally.—*Le Concours Médical*, June 11th, 1887.

“The Dead Failure, Limited.”

Under this title, Dr. Garraway presents in the *Edinburg Medical Journal* for August, 1887, a humorous and very instructive account of a new medical journal which he proposes to establish. It is designed to record not the successes, but the failures of physicians in diagnosis and treatment. Taking diabetes as an example, he says:

If any mortal malady will make a fool of a man, commend me to diabetes. A patient brings you a sample of urine, loaded with sugar, and of sp. gr. 1040, of which he is passing a gallon a day. You probably give an unfavorable prognosis, put him under treatment, of which after a time he gets tired, abandons it, or seeks out a homœopath—the same thing—and outlives his physician. Diabetes, indeed, plays remarkable pranks—patients dying suddenly when they are getting well, and getting well when according to all physiological laws they ought to die; sometimes doing neither, sometimes both, to the mystification and discomfiture of the bewildered practitioner. Take an illustrative case: A lady at the seventh month of pregnancy consulted me about cedematous legs, such as commonly result from pressure on the iliac veins. The urine gave no indication of albumen; but, on the contrary, was of sp. gr. 1040, and loaded with sugar. Six pints were voided per diem, a corresponding amount of fluids being imbibed. I gave a most unfavorable prognosis, the particular combination of circumstances being new to me. Labor came on at the proper time, was protracted and laborious, the child weighing 13 lbs., dead, and decomposing. Three days after delivery, expecting my patient to go all to pieces, the urine was reduced to five pints, and its sp. gr. to 1030. Now, again, I prophesied better things. From this time, however, the sp. gr. gradually rose till, on the twelfth

day after confinement, it attained the maximum of 1050, the sugar being more abundant than ever. The friends were now prepared for a fatal issue before long. At the end of six weeks every trace of sugar had disappeared, the sp. gr. was abnormally low, 1015, and the quantity of urine normal. I now felt justified in pronouncing my patient perfectly well, and accepting with dignity my just meed of praise for the very able, etc., etc. The lady removed into a distant county, and in a few weeks I was informed that she had died of diabetes, her friends giving me politely to understand that the case had been bungled over and misunderstood from beginning to end. A waggish relative, moreover, on receiving my modest account, said it irresistibly reminded him of the bill of the well-known farrier of "Ivecum, Bux," commencing "To curin a ors wot died," and he trusted I should never have another opportunity of adding the blacksmith's second item, "To ditto a ditto wot ditto."

One more case and I have done. A gentleman in an advanced stage of Bright's disease, and whose friends I had prepared for his approaching end, became suddenly worse. On my arrival they told me he had been getting much weaker, and acting upon other instructions, for he was then thirty miles distant from my house, and I saw him but twice a week, they had been sustaining him as well as they could upon brandy and water. I found him lying on his back, comatose, bathed in sweat, with eyelids dropped, jaw fallen, breathing stertorous, sphincters relaxed, and death imminent. There was no hesitation in saying that this was the natural and looked-for result of the malady, that uræmic poisoning had set in, and his last day had arrived. Telegrams were dispatched in all directions to summon his relatives; and as it was not considered that so great, *i. e.* rich, a man should die without the sanction and approval of some eminent London practitioner, Dr. Samuel Wilks was sent for, and came down in hot haste. This astute physician, after carefully examining the patient, led me into the ante-room, and here is our consultation reported verbatim. Wilks *loquitur*—"Well, Garraway, your patient is beastly drunk; let him alone, and he'll be all right to-morrow." It needs not to say further that I looked and felt—well—small. The old gentleman survived some weeks, dying of legitimate uræmia at last.

Gentlemen, I venture to hope that you will all enroll yourselves shareholders in "The Dead Failure, Limited."

Salix Nigra as a Sexual Sedative.

In many women pain in the ovarian region is a constant attendant upon the menstrual epoch. In some this is due to organic disease, but in a large number it is one of the manifestations of the neurotic temperament. Such cases are met with in all degrees of severity, from a slight amount of discomfort along with indications of globus hystericus, up to hystero-epilepsy in its most pronounced forms.

It has always been a slur upon our profession that when a method of treatment becomes popular or fashionable other methods are entirely discarded. At present, massage and isolation from relatives is the popular mode of treatment, and drugs occupy a secondary place, if, indeed, they have any place at all. Pecuniary difficulties, however, stand in the way of isolation or massage ever reaching the masses, and drugs will always be in employment. Several drugs are in daily use against the ailment, but with only partial success; and it is with the view of bringing before the profession a remedy which, in my hands, has produced results which I never had before while I was employing the bromides, valerian, assa-fœtida, etc., that I have sent this short notice.

Salix nigra, or the pussy willow, is a tree growing from 15 to 20 feet high. It is met with along the streams in the Southern States of America, and is credited with possessing tonic, carminative and stimulant properties, besides being an astringent and antiperiodic. In the *Transactions of the Texas State Medical Association*, Dr. Paine reports many cases treated successfully with the drug. He prescribed it in cases of ovarian hyperæsthesia, uterine neuralgia, etc., and also in spermatorrhœa and nocturnal pollution. His verdict upon the drug is that it is a powerful sexual sedative, similar in its action to bromide, but without its depressing qualities.

Through Messrs. Thomas Christy & Co., of London, I obtained a supply of the fluid extract, and have been employing it for some months. The most numerous class of cases in which I exhibited the drug were women of nervous temperament, in whom the nervous irritability reaches its height at the menstrual period, when, along with the general *malaise*, is added a very decided pain in one or other ovary. They also suffered from hemicrania, the pain being situated above the left eyebrow, and resembling the feeling as if a nail were being driven into the skull (*clavus*). Many of

them, too, complained of a pain underneath the left breast, and extending round to the back. On one or two occasions I have noticed patients complaining of the above symptoms, and in only a moderate degree, under favorable conditions—as, for example, long-continued anxiety or alcoholism—go from bad to worse till they become hysteropileptics. In cases of this kind, it is supposed that the centre of inhibition has in some way got out of gear, and the severity of the symptoms depends upon the amount of disturbance in this nerve-centre.

In cases where the ovarian distress was the symptom for which advice was sought, as being in the patient's eyes the most prominent, I usually succeeded in eliciting other indications of an irritable nervous system, and placed them upon half-drachm doses of the fluid extract of *salix nigra* three times a day. In quite 75 per cent. of patients so treated a great amount of relief was obtained after two or three days's treatment. Not only was the ovarian hyperæsthesia relieved, but the nervous palpitation of the heart was abated, and the patient felt in every way stronger.

I have also given the drug in two cases of nocturnal emissions with marked benefit. The pollution ceased entirely while the drug was being taken and for several months thereafter. Virile power and passion were not much if at all diminished, but the relief from the ailment gave them great satisfaction.—J. HUTCHISON, M. D., in the *British Medical Journal*, July 30, 1887.

Molline.

Under the name of molline Dr. Kirsten highly extols an excipient which appears to be simply a kind of soap. It is obtained by cold saponification with liquid caustic potash, mixed with a small quantity of soda suds; 30 per cent. of glycerine is then carefully poured into this warm. Molline is of a soft consistency, which varies but slightly in any temperature, and may be kept a long time. It is of a yellowish-white color; its reaction is neutral. Dr. Kirsten considers it to be a good therapeutical excipient in diseases of the skin; mercurial molline, in the same proportions as Neapolitan ointment, is easily prepared and very active. As an excipient for preparations of styrax, liquid pitch, salicylic, carbonic, and tannic acids, white and red precipitates, chrysarobin, ichthyol, sulphur, thymol, molline may be recommended to dermatologists.

Therapeutic Scraps.

Freckles.—Hager removes these evidences of sunshine with an ointment composed of white precipitate and subnitrate of bismuth, of each, 5j; glycerine ointment, 3ss. Each freckle is touched with the ointment every other day.

Itching Piles.—The intolerable itching of external piles is said to be relieved by the application of a lotion composed of turpentine, 2 parts; spirits of camphor and colorless tincture of iodine, of each 3 parts.

How to Cure Warts.—"Place the thumb upon the wart, and press it against the bone. Move the wart backwards and forwards upon the bone until the roots become irritated or sore, when the wart will disappear." So says a correspondent of the *Scientific American*.

Sweating of the Feet.—Great relief is sometimes afforded by a foot-wash made by adding one-half ounce of solution of subacetate of lead, diluted with water enough for a foot-bath. Hebra recommends an ointment composed of equal parts of lead plaster and linseed oil spread on linen, and wrapped round the feet, renewing the application every third day for nine days.—*Chemist and Druggist*.

Treatment of Diarrhœa by Iodoform and Charcoal.

Picchini records the successful treatment of eight cases of diarrhœa, with symptoms of fermentation, by the following mixture:

R	Iodoform.....	grs. 9.
	Ether.....	3 3/4.
	Vegetable charcoal, finely powd.....	3 3/4.
	Glycerin.....	ad 3 12.

The iodoform must be dissolved in the ether, and the powdered charcoal thoroughly mixed. After the ether has evaporated, the glycerin should be added. It is given in teaspoonful or tablespoonful doses, suspended in a glass of water.—*Journal de Médecine*.

Milk and Phthisis.

In a paper read at the recent meeting of the Yorkshire Association of Medical Officers of Health by Dr. Mason (Hull) he expressed the opinion that milk which had been obtained from cows affected with tuberculosis would convey consumption if supplied to human beings. The President said it was very important that tuberculosis should be included in the list of contagious diseases by the Privy Council, as consumption, which in his opinion was preventable, destroyed more people in a year than all the contagious diseases put together.

Hydrastis Canadensis.

In his inaugural thesis, Joseph Jermans reports that *hydrastis canadensis* has been used in Martin's polyclinic in about forty cases, twelve of which he reports accurately. The action began after two or three days; at other times, especially in myomas of the uterus, it failed. It was of use in menorrhagia, metrorrhagia, with or without tissue change or malposition, in menstruation, in bleeding after metritis, endo-para—or perimetritis, after subinvolution of the puerperal uterus, and in bleeding from a pregnant uterus. He has employed it in doses of fifteen to twenty drops four times a day.—*Allgemeine med. Central-Zeitung*, July 6, 1887.

NOTES ON CURRENT LITERATURE.

—Professors Weigert and Unverricht have undertaken the editorship of the *Fortschritte de Medizin*.

—We have received the first number of the *Monthly Bulletin of the Iowa State Board of Health*, published in Des Moines, at twenty-five cents per year. It contains not only the official announcements of the board but much other valuable matter.

—The illustrated articles on "Astronomy with an Opera-Glass," appearing in the *Popular Science Monthly*, are continued in the August number, with a very interesting account of what can be seen on the moon and the sun with a small glass.

—We have just received the Tenth Annual Report of the State Board of Health of Wisconsin, for the year 1886. The organization displays admirable energy and executive ability.

The autobiography of the late Dr. Samuel D. Gross has just been issued from the press of George Barrie, in two very handsome octavo volumes, of over 400 pages each. The work treats of the men and times of Dr. Gross's long and active professional life, and cannot fail to interest a large circle of readers.

—Dr. J. Milner Fothergill's original essay on "Vaso-renal Change *versus* Bright's Disease," with its colored plates from Dr. Bright's originals, and its numerous uncolored illustrations, is to be issued by the Putnams.

REVIEWS AND BOOK NOTICES.

BOOK NOTICES.

Transactions of the New York State Medical Association. 1886. Vol. III. New York, 1887.

This bulky volume is made up of eleven surgical papers, three medical papers, an address on medical jurisprudence, and lengthy reports of discussions on 1st. Shot Wounds of the Intestines; 2d. Pulmonary Tuberculosis; 3d. Eclampsia. The first was introduced by Dr. Tremaine, and five important referred questions appertaining to the subject were answered by distinguished surgeons. To add to the interest the Association invited surgeons from a distance to answer some of the questions, and Nancrede, of Philadelphia; Varick, of Jersey City; Parkes, of Chicago, and Hamilton, of Washington, sustained their home reputations by vigorous, matter-of-fact arguments of their respective questions. In the same discussion ten questions were propounded, and the names of Didama, Cronyn, Biggs, Elsner, Flint and Shady are sufficient guarantee of the valuable character of the papers.

Dr. Lusk opened the discussion on eclampsia, and Tyson, of Philadelphia, Taylor, Thomas (T.G.), Harrison, Colvin, Macgregor and Blumer, of New York State, handled the four collateral questions introduced for discussion.

We mention this feature to call the attention of other associations to the interest taken in these discussions, and would suggest their adoption by kindred societies.

Memoirs of Austin Flint, Frank H. Hamilton, John P. Gray and others, add to the interest of the volume.

What to do in Cases of Poisoning.

By William Murrell, M. D., etc. First American from the Fifth English Edition. Edited by Frank Woodbury, M. D. 16mo, pp. 158. The Medical Register Company: Philadelphia, 1887.

We regret that we have discovered no evidence in the book that it is published in this country with the consent of its author, but rather in a way which an International Copyright Law—for which we still hope—will put an end to. When this sort of thing is done in England, we do not like it, and when it is done in America, we do not like it any better.

Anæmia.—By Frederick P. Henry, M.D., etc. Philadelphia: 1887. P. Blakiston Son & Co.

In this monograph of one hundred and thirty-five pages Dr. Henry gives this, "the first systematic treatise on Anæmia published in this country," to the profession. Those readers who are familiar with the long-continued and exhaustive original work of Dr. Henry on the blood will expect a complete treatise. They will not be disappointed; for in this brochure the subject is treated in full in a clear and concise manner in a style smooth and attractive. Space will permit but a cursory review of the mass of facts presented and the jotting down of only a few of his noteworthy observations. The first fifteen pages are devoted to a consideration of the blood and the methods of its examination. We heartily endorse this sentence: "It is a significant fact that those who, in the course of their practice, make frequent examinations of the blood, encounter cases of disease never met with by others, with perhaps much greater opportunities of observation; just as the oculist has become able by improved the clinical methods, to classify cases formerly vaguely known as 'amaurosis,' into retinitis, choroiditis, atrophy of optic nerve."

What stronger plea could be made for the use of the hæmocytometer, if columns even should be filled?

The term "anæmia" is preferred by the writer to spanæmia, olygæmia, etc., on the ground of etymology and euphony, and because it possesses its exact equivalent in the French and German language—"anémie" and "anæmia." All the varieties of anæmia have in common the one characteristic—a diminution in the number of the red blood corpuscles, i. e., of the normal amount of hæmoglobin. It is not a neurosis or a functional disorder, but a systemic condition dependent upon a lesion which can be demonstrated with the utmost precision. The pre-disposing causes or conditions of anæmia in general are considered and we learn among other matters that anæmia may be congenital, and in the other extreme it may be "classed among the tissue changes known to the histologist as 'senile,'" and that it is at the root of "the degenerations of the walls of the small blood-vessels" in old age. Dr. Henry lays great stress on hemorrhage, and properly, as well as on *fever*, as the most frequent exciting causes of anæmia. The reader is doubtless familiar with the work of Dr. Henry which demonstrated the occurrence of "latent anæmia" in typhoid fever, due to the loss of fluids by the heat and the anatomical

observations, which corroborated the clinical studies of the late Dr. J. Forsyth Meigs, who strongly urged supplying water freely to fever patients.

The writer observes that the symptoms attendant upon a severe hemorrhage are not due, as is usually thought to acute anæmia, but to a sudden ischæmia of the nerve centres. The same symptoms precisely are produced by the application of Junod's boot to one of the lower extremities.

We miss any mention of the use of salts of iron in effervescence in the anæmia of persons with a delicate stomach. Blaud's pill he places upon the list and then the lactate, the pyrophosphate, the mallate and Quevenne's powder. Arsenic is lauded.

Chlorosis, lymphatic and splenic anæmia, leucocythæmia and pernicious anæmia compose the class of primary anæmias; and the writer further subdivides the affection into secondary anæmias (of fever, hemorrhage, phthisis, etc.); toxæmias (lead, arsenic, etc.); and parasitic anæmias (anchylostomum duodenale, filaria, etc.). The primary anæmias are discussed in full, and wide knowledge and good analysis are especially shown in the account of the grave and intricate problems involved in the pathology of the respective affections.

Briefly the writer puts chlorosis as the anæmia of puberty, at which period there is an urgent physiological demand upon the blood, without detriment to the vigorous, causing anæmia in the less vigorous, and in those with a congenital tendency to anæmia, the latter being most intense—a typical chlorosis.

Anæmia lymphatica is an infective hyperplasia of the lymphatic tissue of the body, with progressive anæmia. The writer believes in the occurrence of splenic and medullary leucocythæmia, and not of the lymphatic variety. The nature of leucocythæmia is hypothetical. In anæmia splenica the enlargement of the spleen is primary, the anæmia secondary. Either the enlarged spleen destroys the red corpuscles, or it forms materials which enter the circulation, and interfere with the functions of hæmatopoiesis. It is the splenic form of pseudo-leucæmia.

Following Coupland, this author believes that pernicious anæmia is the final stage of severe forms of symptomatic anæmia and of chlorosis. In this form of anæmia there is a transition to the type of blood found in lower animals. We could continuously quote good things, but leave the book, however, with the great satisfaction of being the better informed for it.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, -	6.00
Physician's Daily Pocket Record, -	1.50
Reporter and Pocket Record, -	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,000 copies.

SPECIAL NOTICE TO SUBSCRIBERS.

Subscribers to the MEDICAL AND SURGICAL REPORTER, who have remitted payments to the former editor, and who do not find upon the wrapper of their journal a correct statement of the time up to which they have paid, are requested to notify the present publishers as soon as convenient.

SCARLET FEVER AND MILK.

Among the interesting questions of public health which have recently come to occupy so much of the attention of medical men and of the whole community, none is of greater interest than that which concerns the mode of propagation of scarlet fever.

While certain physicians actually deny the contagious nature of scarlet fever, the great majority do not doubt it, and all consider it prudent to act as if its contagiousness were beyond question.

Recent investigations in England seem to indicate that scarlet fever, in addition to being contagious is also communicable by means of milk. Nearly two months ago, Klein delivered a lecture before the Royal

Institute on the milk of diseased cows as a source of scarlet fever. In this lecture he cited some strong evidence in favor of the theory that the poison of scarlet fever may be communicated to milk and by this conveyed to hitherto unattacked individuals. He mentioned endemics of scarlet fever which seemed to be distinctly traceable to the use of milk from farms on which scarlet fever was present. In some of these endemics it even appears that persons who drank the suspected milk uncooked contracted scarlet fever, while those who drank only milk which had been boiled escaped. When it is considered that boiling destroys the life of micrococci, it will be seen that the fact just stated makes a strong piece of confirmatory evidence. So that while Klein may be all wrong, there is enough reason for further investigation of this subject, and for acting as if the point were established, until we have information to the contrary.

But Klein's studies have touched another point of the greatest interest; he believes that milch cattle may acquire from human beings affected with scarlet fever a disease like it, but milder and harder to diagnose, which in turn may give scarlet fever to other human beings. The evidence which he adduces to prove this belief is not so strong as that he advanced in regard to the former point; but still is strong enough to demand careful consideration, and to warrant great vigilance on the part of dairymen and farmers that no cattle affected with scarlet fever should be used for milking.

The obscurity which still surrounds this subject is largely due to the ignorance of veterinary surgeons, as a class, the majority of whom have very little knowledge which could strictly be called scientific. At the same time it may be that Klein's ability to diagnose modified scarlet fever in cattle is much assisted by his zeal for his new theory.

Such being the facts in regard to this subject, we commend it to the observation and study of our readers, some of whom may before many months have excellent opportunity to confirm or to correct the opinions of Klein.

ANTIPYRINE IN SUBCUTANEOUS INJECTIONS, AS A SUBSTITUTE FOR MORPHIA.

Professor Germain Sée has just communicated to the Paris Academy of Medicine the results of his experience in the Hotel Dieu with antipyrine in subcutaneous injections, as an analgesic. The solubility of antipyrine in distilled water favors this mode of employment, eight grains being readily dissolved in a hypodermic syringeful of water. The injection causes a brief painful sensation of tension, then there is a considerable lull in the pain, whatever may be its cause.

Professor Sée finds that these subcutaneous injections have none of the ill effects which almost constantly attend the hypodermic introduction of morphine, such as vertigo, or vomiting; there is no danger of too deep or too prolonged somnolence, and, moreover, to its calmative action, antipyrine often conjoins that of a curative action. He calls attention to a series of cases of acute rheumatism which were signally benefitted by two or three injections of half a gramme of antipyrine; to one case of acute gout, very painful; to several cases of chronic gout and nodular rheumatism, which were in a marked manner relieved and favorably modified by antipyrine employed subcutaneously and taken internally.

Some of Prof. Sée's most signal successes were cases of neuralgia. Three patients suffering from tic douloureux of the face, one of three years standing, another of five weeks, and the third of six days, were permanently relieved in several hours; these cases came under the observation of several of Prof. Sée's colleagues. Several cases of zona of long standing were cured; and the same may be said of cases of migraine (one of these was ophthalmic migraine). He considers as deserving of special mention the relief given in the lightning pains of locomotor ataxia; some of these sufferers were enabled by means of a daily injection of antipyrine, and three or four gramme doses by mouth, to dispense altogether with the morphine to which they had become accustomed.

In bilious colic, where morphine injections have heretofore been deemed necessary (despite the fact that morphine diminishes the biliary and intestinal secretion), antipyrine injected subcutaneously has relieved the pain quite as effectually as morphine, and without any of the disadvantages above-named. In three cases of nephritic colic, there was the same favorable result, without, of course, any arrest in the urinary secretion.

In painful affections of the heart, and angina pectoris in particular, hypodermic injections of antipyrine have markedly reduced the number and intensity of the attacks, without any disturbance in the cerebral circulation.

In attacks of asthma, whether bronchial or spasmodic, antipyrine has afforded relief without suppressing the bronchial secretion; but it should be reserved principally for the acute paroxysms, when iodide of potassium has lost its effects, and when morphine succeeds only in large or frequently repeated doses.

Prof. Sée concludes that thus far his experience hardly indicates an instance where the hypodermic use of antipyrine may not profitably be substituted for that of morphine. We have thus at hand, he adds, a means of avoiding that fatal morphinism, with all its grave cerebral and other organic troubles, into which so many are led by reason of the physical suffering from which they are impelled to seek deliverance. Antipyrine seems to him to be the ideal analgesic, assuaging pain, and diminishing the reflex excitability of the cord; it ought to be of great use in the vague, general, nervo-muscular pains of hysteria and other neuroses. Being absolutely safe, it must tend more and more to supplant morphine.

SOLUBLE SALT OF QUININE, FOR HYPODERMIC USE.

Signor Erba, of Milan, prepares an acid hydrochlorate of quinine, which is sent out as an amorphous, yellowish white powder, soluble in one and one-half times its weight of water, and producing little local irritation when used, in saturated solution, for hypodermic injection.

NOTES AND COMMENTS.

Rupture of the Bladder in an Ox.

Dr. G. W. Squires, of East Avon, N. Y., writes: "A farmer lost a valuable ox, with the following history and autopsy: He had been in the habit of watering the team at the house well, which water was strong in the ingredients of lime. The ox was twelve years old, and had drunk of this water eleven years. It had at times shown signs of vesical trouble, but never to a degree to incapacitate him for work. He was found in the stable one day in great distress, lying down and getting up, turning round and round, swinging his head around to his haunches, and visibly in excruciating agony. He remained in this condition two days, all remedies failing to alleviate, but at the end of this time he was found lying down, apparently comfortable; he ate and drank a little, but with fastidious relish. For three days he lay down most of the time, and was noticed to be very thirsty—would drink great quantities of water. He now began to bloat, and there was a discharge of frothy water from the mouth and nose, increasing in quantity until it flowed almost in a stream. The ox appeared to be in little pain, but died on the seventh day. The examination revealed rupture of the bladder at the fundus, with slight hemorrhage. The abdomen contained eight common-sized pailfuls of water, of a urinous color and odor. Numerous small calculi, from the size of a number six shot to a good-sized pea were found impacted at the neck of the bladder. The bladder contained one hundred and fifty of these calculi, about one hundred and twenty-five of them being of the smaller size. They were most of them perfectly round, and of surpassing smoothness and beauty. The calculi, becoming impacted in the neck of the bladder, doubtless caused spasmodic closure of the urethral outlet, causing retention of urine, until the viscus was dilated to such a degree as to rupture, after which the pain was alleviated, the water passing through the tear into the abdominal cavity."—*N. Y. Med. Record*, July 16, 1887.

Melon Root as an Emetic.

Heberger in describing the bitter principle of the cucurbitaceæ attributed emetic and purgative properties to melon root. Torosicvitz has found that the emetic principle is a bitter substance extractable by alcohol from the aqueous extract of melon root, which he designates as *melon emetine*.

It occurs in compact brownish masses, breaking with a shining fracture. It is very deliquescent. The aqueous solution has a biting, bitter taste. It does not react with alkalies or acids, and colors ether. It quickly dissolves in alcohol, but is readily precipitated therefrom by lead acetate or infusion of galls. Liquor ammonia and liquor potassa dissolve it readily, and from the resulting solution a brownish-gray precipitate is thrown down on addition of acid, which is rather insoluble in water. Recent experiments show that a grain and a quarter of melon emetine produce vomiting. Dr. Langewicz states that the wild plants contains more melon emetine than the cultivated.

Note upon an Undescribed Variety of Vertical Fracture of the External Malleolus by being pulled asunder.

The *Centrallblatt für die med. Wissensch.*, for June 18th, reports the following case, which occurred in the practice of Léon Lefort: A young man, aged eighteen, made a misstep in which the left foot was twisted (rotated) inwards upon its vertical axis, so that the toe was in forced adduction. A simple sprain was suspected and massage used. Examination with the blunt point of a pencil, two days after the injury, showed only tenderness of the anterior border of the external malleolus. This tenderness did not extend toward the fibula, but upon the anterior tibio-fibular ligament. Here it very much diminished, and entirely disappeared at the tibia. Lefort supposed the external malleolus was fractured by being torn asunder in the long axis, and based this opinion, as in three other similar cases, upon the fact that in strong adduction of the foot the external surface of the end of the tibia may exert strong pressure upon the articulating surface of the fibula, which pressure is transferred to the posterior border of the tibia.

Bergeon's Treatment at Ventnor.

Dr. Sinclair Coghill reports his experience with this treatment at the Isle of Wight as follows: My experience, so far, of Dr. Bergeon's treatment of consumption and other lung affections, both in private and hospital practice, has been altogether most encouraging—indeed, in some instances, surprising. I believe it is the greatest advance by far that has ever been made in the therapeutics of pulmonary diseases.—*British Medical Journal*.

On the Neurotic Treatment of Summer Diarrhoea and Cholera Infantum.

Dr. Alexander Harkin, of Belfast, England, writes as follows in the *Boston Med. and Surg. Journal*, of July 14, 1887:

The cramps and spasms, the great depression of the nervous system and the powers of life, the convulsions of so frequent occurrence, and the stage of collapse which so often terminates the infant's existence, all betray the neurotic origin of the disease, and a lesion of the nervous centres.

According to Claude Bernard, the stage of collapse in cholera is referable to great irritation of the sympathetic nervous system, and, as most authorities regard cholera, choleraic diarrhoea, cholera infantum, cholera nostras, and Asiatic cholera as one in nature, but only differing in degree, if we accept the dictum of the great physiologist in the major, we may fairly apply its teachings to the other divisions of the class. Having for many years been converted to his views on this subject, I have formulated my plan of treatment accordingly, and, knowing that the pneumogastric is the antagonist and controller of the sympathetic nerve in the abdomen, I invoke the action of that spinal nerve by applying over its sheath in the neck a rapidly acting vesicant, the liquor epispasticus of the British Pharmacopœia, with the almost uniform result, that as soon as its powerful irritation is experienced, all vomiting, purging, and cramps immediately cease, natural heat returns to the body, the patient, be he child or adult, generally falls over asleep, and finally awakes, in a few hours, quite free from danger. I apply the fluid with a camel's hair pencil from behind the ear, as far as the angle of the lower jaw, over a space three inches in length and one in breadth; a blister rises in five hours, which I dress with cotton-wool.

In the preliminary stage I enjoin absolute repose, with warmth to the surface and extremities; total abstinence from mother's and cow's milk; order, when available, condensed milk, or as an alternative, arrow-root prepared with water, and the free addition thereto of port wine fairly sweetened; it is wonderful how much wine thus administered an infant of a few months will both require and consume; and beef tea carefully freed from fat; then counter-irritation over the abdomen by poultices and sinapisms; and failing these remedies, *a small blister over the region of the liver*. This latter procedure will often be found most salutary and successful. As internal remedies, having long since discarded the old-fashioned chalk

mixture and astringent tinctures, my chief reliance is placed on dilute sulphuric acid, with or without tincture of opium. If given alone, the acid may be taken after every loose motion; if with laudanum, then in regulated and specific doses. One argument for its use derived from recent speculation may be advanced, namely, that the microbes, to whose influence so much of the choleraic discharges are attributed, cannot live in an acid medium, but perish at once. Of course if milk be persisted in, as an article of food, the acid mixture will be the cause of increased griping and pain.

The simplicity and safety of my plan of treatment has been thoroughly tested by myself and many others for several years past, and might be expected to commend itself in the cure of a class of diseases, so little amenable to ordinary medication. But personal experience in a profession noted for great caution in the acceptance of new proposals, and even open sometimes to the charge of so-called scientific scepticism is not always sufficient.

The Treatment of Consumption.

In answer to the question,—“Given a case of consumption in an early stage, among the artisan or laboring classes, what can be done to prolong life and make the disease less distressing?”—Dr. Robert Esler (*Dublin Journal of Med. Science*, July, 1887) advises super-alimentation, cod-liver oil and iron, with avoidance of night air and undue exposure to cold. He narrates one case of many, which, after seven years of such regimen, followed his occupation as regularly as did his fellows.

For *cough* he advised, if actually necessary, ten minims of liq. morphinæ. Good results can be obtained, and sedative effects produced quickly, by a glass of hot water. For old people, a little old whiskey and sugar is useful. Sleepless nights are dispelled by a little morphine, chloral or a one-grain opium pill.

Quinine may be used occasionally for fever and loss of appetite, but a mixture containing tr. ferri chloridi, potas. chlorat. and spt. chloroform, is the most useful in his practice. As a clinical observation, he believes the good effects of the iron as a stimulant to the gastric mucous membrane and a local action on the intestines, cannot be disputed.

He calls attention to the following important methods of treatment:

Rest—not of the body, but of the weak lung—by strapping the chest with porous plaster cut in strips, or with Mead's porous plaster, nicely adjusted from spinal column to sternum. This gives much relief, and quiets cough.

Inhalation: Breathing the steam from boiling water, into which some of the terebene or antiseptic group of remedies have been introduced, is of value. Any of the various inhalers, or an ordinary jug, will do very well. *Ol. Pinus Sylvestris*, or, better, carbolic acid, and *tr. benzoin. comp.*, seem to answer best. They allay irritation, quiet cough and act locally on the disease.

Feeding, or cramming, is also advocated.

In the same journal, Dr. Wales's treatment of phthisis is epitomized. He finds the new antipyretics are not equal in duration of effect to quinia, digitalis and salicylate of sodium, singly or in combination.

In the chronic form of the disease he prefers a regimen which includes pure air—preferably a sea voyage—and attention to digestion.

As special remedies, he uses: 1. Counter-irritation, with equal parts of the liniments of iodine and of belladonna. 2. Inhalations of carbolic acid for diminution of profuse expectoration. 3. Gentle and appropriate sedatives for cough. "Grape-shot cough mixtures" are abjured. 4. Oxide of zinc and belladonna pill for night-sweats. 5. Cod-liver oil with Fairchild's pancreatine for the general nutrition. Secondly, the hypo-phosphites, and chloride of lime or iron in glycerine. 6. Turpentine (10-drop doses internally and inhalation of the vapor) will generally answer for hæmoptysis. Dry cupping, counter-irritation, acetate of lead, gallic acid and ergotin, are likewise of value. The use of caution as to the effects of carbolic acid and turpentine on the kidneys, is recommended in the direction for their respective uses.

A Study upon the Treatment of Diphtheria.

Dr. Palcardy writes as follows: For thirty years I have every year treated several cases of diphtheria, and in some years have observed epidemics. In young children cauterization is next to impossible, but in adults it is easy, though disagreeable. I have always employed it in adults, conjoined with constitutional treatment, and have never, from the time I commenced the treatment, had a single unsuccessful case within the first twelve hours of the disease. This is the procedure: As soon as diphtheria

is recognized, I apply at once cauterization with a solution of carbolic acid:

R Acid carbol..... $\frac{3}{4}$ j
Glycerini..... $f\frac{3}{4}$ ij
Aquæ..... $f\frac{3}{4}$ j

M.

The throat, tonsils and all affected parts are painted with this solution once or twice a day. After cauterization, the throat is gargled with some soothing liquid, such as:

R Potass. chlorat..... $\frac{3}{4}$ j
Tr. ferri. chlor..... $f\frac{3}{4}$ j
Aquæ..... $f\frac{3}{4}$ viij

M.

For constitutional treatment, the following is prescribed:

R Potass. chlorat..... $\frac{3}{4}$ i- $\frac{3}{4}$ iv
Tr. ferri. chlor..... $f\frac{3}{4}$ ss
Aquæ..... $f\frac{3}{4}$ iv

M. Sig.—Teaspoonful or more every hour, with brandy, wine, beef tea, etc.

The character of this disease being asthenic, you must not give any weakening agent. The basis of treatment ought to be stimulant and tonic, the rest being symptomatic. The treatment by cauterization is regarded as a local stimulant, and hence as an adjuvant to constitutional stimulation. After such cauterization I have always noted an improvement in the appearance of the ulcerations. The false membrane is reproduced, but is very often thinner, less organized and smaller. This renewal is rather the consequence of the progress of the disease than the result of cauterization. I have rarely been obliged to cauterize more than twice day.

To assist the other treatment, sulphur is burnt in the patient's chamber. These emanations of sulphurous acid which form in the air, besides acting as a disinfectant, have also a direct action in dissolving the false membrane, either chemically or by stupefying the bacteria of contagion.

The author employs a few whiffs of chloroform in the dyspnœa occurring in diphtheritic paralysis. This probably causes a disappearance of the spasm of the glottis. In adults he has had a mortality of scarcely one or two per cent., though in young children scarcely three or four per cent. are saved.—*L' Union Médicale*, July, 1887.

—Application has been made in the Common Pleas for a charter for the Visiting Nurse Society of Philadelphia, whose purpose is "to furnish visiting nurses to those otherwise unable to secure skilled attendance in time of illness, to teach cleanliness and the proper care of the sick."

CORRESPONDENCE.

A Bundle of Letters.

Very cordial and cheering words, commending the conduct of the REPORTER, reach us almost daily. They indicate that the ideal relation of personal friendship and confidence existing between a journal and its readers is not unattainable. To many readers these brief and cordial notes will prove a pleasant confirmation of their own judgment. To others, with whom all this is a matter of course, it may seem that we are unwarrantably trenching upon the thirty-two pages of new ideas which are each week due. We believe in full measure, too, and for that reason give two extra pages in this issue, and, without further apology, present some of the letters and our thanks:

I have taken the REPORTER for eighteen years past, and I like it somewhat better than under the *old* management. Give us all you can of the experience of country practitioners and not *too* much ophthalmology and learned writings on specialties.

J. W. DONNALLY.

Doddsville, Ill., June 30, 1887.

EDS. MED. AND SURG. REPORTER:

I am a subscriber to several medical and other journals. I find it quite a pecuniary tax to add to the number without stopping some. But as the REPORTER has long been a familiar friend and monitor, I thought that I should probably miss its weekly intellectual feast and so go hungry, and therefore have concluded to renew my subscription, which please find enclosed.

With esteem and respect,

THOMAS W. BENNETT.

Jeffersonville, N. Y., June 30, 1887.

The REPORTER is, indeed, a model journal, the best I have ever seen.

FAYETTE C. EWING, M. D.

Washington, D. C., July 6, 1887.

* * * * Certain it is that the REPORTER has very much improved under the present administration.

Yours truly,

E. P. HURD, M. D.

Newburyport, Mass., July 7, 1887.

Find enclosed \$5.00 for payment of my REPORTER to July, 1888. Feel I cannot get along without it.

A. NOEL SMITH, M. D.

Dover, N. H., July 6, 1887.

* * * * I have been a continuous subscriber for THE REPORTER since January, 1864. It always was a good journal and under the present management is even better than before.

DR. H. S. WOLF.

New Albany, Indiana, July 8, 1887.

* * * * I have taken the MED. AND SURG. REPORTER since 1876, and am very well pleased with it under the new management.

W. N. SHERMAN.

Kingman, Arizona, July 8, 1887.

Editors MEDICAL AND SURGICAL REPORTER:

Sirs:—Please forward my REPORTER to Benetzette, Elk county, Pa. Find enclosed amount of subscription due.

The improvement is so marked that I cannot afford to do without it.

Very truly, J. E. FREES.

Benetzette, Elk Co., Pa., July 11, 1887.

EDS. MED. AND SURG. REPORTER:

Sirs:—In 1860–1–2, I was associated with S. W. Butler, M.D., and Dr. R. J. Levis in the editorial management of the REPORTER. I have a complete file of it, bound and unbound, from its first issue down to the present time. I value it highly, and have always considered the REPORTER as the only medical journal which represented the *profession*, and not some publishing house.

I am pleased to observe the vigor and zeal you manifest in its conduct, and the efforts you are making to infuse into its pages more of life and professional enthusiasm.

I belong to the army of older physicians, but have lost none of my early interest in the profession, nor in the progress now making in its various departments.

Yours respectfully,

S. C. BUTLER, M.D.

Essex, Vt., July 11, 1887.

I have read the REPORTER for nearly twenty years and like it very much.

H. N. BURR.

Williamson, N. Y., July 12, 1887.

I am glad to note the healthfulness and independence of your editorials.

E. T. BLACKWELL.

Cedarville, N. J., July 25, 1887.

EDS. MED. AND SURG. REPORTER:

Sirs: * * * Your valuable Journal reaches me regularly, and suffer me to congratulate you on its improvement since it has fallen into your hands.

F. W. DANCY, M. D.

Holly Springs, Miss., July 30, 1887.

EDS. MED. AND SURG. REPORTER:

I cannot do without the REPORTER, as I am an old subscriber and have all our volumes bound for the past eleven years.

NATHAN HOLMES.

San Jose, Ill., July 18, 1887.

EDS. MED. AND SURG. REPORTER:

I do not think that I could get along without the REPORTER as long as it is published in the style that it is. I think it is the best journal published in the United States. It has been taken by some member of my family nearly ever since it was established.

E. J. POWELL, M.D.

Maysfield, Texas, Aug. 1, 1887.

EDS. MED. AND SURG. REPORTER :

After carefully reading and reviewing the new REPORTER, I feel like tendering you my compliments. It is just what every educated physician needs, because it develops the necessity of progression.

N. W. TRUXAL, M.D.

Brownsville, Pa., Aug. 6, 1887.

EDS. MED. AND SURG. REPORTER :

In former years I was a subscriber to the MEDICAL AND SURGICAL REPORTER, and then again last year and now. It is no disparagement to the former editors to say the present management has improved the REPORTER.

F. H. VAN EATON, M.D.

Clearwater, Kansas, Aug. 4, 1887.

Then, last but not least, comes this very pleasing instance of editorial courtesy from our valued exchange, *The Peoria Medical Monthly*:

Dr. D. G. Brinton has retired from the editorial chair of the MEDICAL AND SURGICAL REPORTER, of Philadelphia. This change was occasioned by some differences arising between Dr. Brinton and the owners of the REPORTER. While the loss of Dr. Brinton to medical journalism is one to be regretted, his successors, Drs. Randolph and Dulles, will not fail in their earnest endeavors to bring the REPORTER up to a high-water mark of literary excellence and professional favor. Their journal already bears evidence of new life and energy, and we feel assured that the friends of the REPORTER—and they are numbered by the thousands—will not lastingly regret the change.

“Waiting for Nature.”

When nature delivers a primipara, she accomplishes her work within a certain period of time, and we call the case a *natural* one. The vast majority of cases are thus delivered without the aid of art. If nature fails to do her work within the prescribed limits, even though in every other respect the case is natural, the moment the case transcends those limits the case becomes *unnatural*, and every minute of time thus borrowed is fraught with danger to the child first, and then to the mother, and calls loudly for whatever assistance art can afford. As certain as I am of my existence I am sure that in my first years of practice, I have stood by with folded arms “waiting for nature,” and stupidly sacrificed unborn babes to the blind prejudice existing against “meddlesome midwifery;” when a very little assistance with the forceps, sufficient merely to bring the head down upon the perineum, would have rewarded the suffering mother by ushering in in due time the long cherished moment when she could look upon the face of her first born. Time alone may render a case unnatural that is in every other respect natural, and it is *not* meddlesome midwifery in such cases to render instrumental assistance.

It is not a little surprising that at this late day any practitioner of midwifery should question, either directly or indirectly, the value and importance of the proper use of forceps. That Dr. A. has, in a practice of forty or fifty years, never had occasion to resort to them, or that Dr. B., in an attendance upon over two thousand cases, never met with one requiring their use, is no evidence upon which to base a proposition so sweeping as that they are *never* required, or are too frequently resorted to. If I was as sure of heaven as I am of having, by their use, saved the lives of mothers and *many* babes, my cup of joyful anticipation would be running over. DR. H. V. SWERINGEN.

Large Doses of Morphia.

EDS. MED. AND SURG. REPORTER,

Sirs :—The following brief statement may be of interest *apropos* of Dr. Sweringen's account in a recent number of the REPORTER: I treated a case of acute peritonitis last winter in a robust woman, 30 years old. She was kept under the influence of morph. sulph. for 25 days, during which time there was no evacuation of the bowels, and for 12 days she took one grain of morphia every half hour. Recovery perfect.

A. ADY, M.D.

Muscataine, Ia., July 19, 1887.

Recovery from the Toxic Effects of a Tobacco Enema.

As numerous instances of death from tobacco enemas having been recorded, it may be interesting to report a recovery from severe toxic symptoms produced in this way. The infusion was prepared from a pipeful of tobacco in a pipe which had been in continuous use for four years, and consequently saturated with nicotine. Of this, about two fluid ounces were introduced into the rectum of a child four years old for the destruction of seat worms. Vomiting and tenesmus ensued almost immediately, a portion of the enema was ejected, and severe convulsions followed. When seen, scarcely ten minutes after the administration of the drug, the patient was in a severe general convulsion; respiration oppressed, pulse rapid, and pupils dilated.

The prompt administration of soap enemas, external rubefacients (repeated hot baths, sinapisms, etc.) with alcohol freely internally, were followed by a rapid improvement of all the symptoms, and recovery followed.

JAMES K. YOUNG.

Philadelphia, Aug. 5, 1887.

Funds for the Congress.

To the Medical Profession:

The local Committee of Arrangements have the pleasure to announce to their American brethren that the widespread desire to attend the Congress is such that the amount of money for the reception and entertainment heretofore deemed sufficient, will be entirely inadequate to provide for the large number that will be in attendance. They are therefore constrained to appeal to their brethren throughout the country for additional subscriptions to the entertainment fund. They feel that to their patriotic countrymen it is only necessary for the fact to be stated in order to secure the sending of such liberal contributions as will ensure the entire success of the social features of this great International gathering, on a scale commensurate with its dignity and importance. Let all Americans come to the front and ensure to *all* the foreign members the full measure of the hospitality of free America. Contributions should be immediately forwarded to Dr. C. W. Franzoni, member of the Finance Committee for the District of Columbia.

By order of the Local Committee of Arrangements.

C. H. A. KLEINSCHMIDT, *Secretary*.

Homœopathy.—Audi Alteram Partem.

EDS. MED. AND SURG. REPORTER:

Sirs: Some questions in a late number of your wide-a-woke journal, in regard to homœopathy, have aroused in the mind of an unprofessional a desire to ask a few more.

1.—Has any system of medicine yet arrived at the stage in which it can claim to be acting purely on principles, and not at all empirically or experimentally? Or if not, may there not be still left an area of common ground, open equally to scientific explorers from the different systems?

2.—Supposing the principles of the old practice to be mainly right, does it inevitably follow that those of homœopathy are all wrong? And *vice versa*. Might not both be included in some larger law, at which our race, if not our age, may finally arrive? If I know that I can work out a problem by arithmetic, and my neighbor knows he can get it by algebra, is either justified in calling the other names?

3.—If a homœopath, in some exigency of his patient, which in his judgment, calls for mechanical or immediate action, resorts to a

cathartic, has he proved himself a traitor to his principles? Or, if an old school physician, observing that his patient has absorbed malaria at unawares, and in infinitesimal doses, should imagine it possible to eradicate it by means as subtle, would he necessarily be a fool?

4.—Might it not be both practicable and profitable for representatives from these two schools to meet in friendly argument, say in the columns of such a journal as yours, each stating, without bitterness or superciliousness, not so much why he thought his neighbor's system wrong, as why he thought his own right? It would at least make very interesting reading for the lay readers of the REPORTER and they are doubtless many.

ONE OF THEM.

EDS. MED. AND SURG. REPORTER:

We presume that when you asked your readers to reply to the statement, "Homœopathy has increased and is increasing in the United States, by answering three interrogatories," you intended the questions to be answered in the interest of truth and science, and not to provoke controversy.

In this spirit I shall endeavor to give what I believe to be the true reasons, although they may conflict with the views of Dr. D. Colvin, of Clyde, N. Y., as published in the July number of your journal.

1. "The number of persons practicing under the name of "homœopathy" is increasing, and they now number, probably, from 10,000 to 15,000 regular graduates in medicine. 2. The patrons of homœopathy are numbered by tens of thousands, and are rapidly increasing yearly, simply because the people have tired of our former heroic treatment and nauseating doses, and hence they went over to homœopathy; at first, in self-defence, and being benefitted by the mild treatment, they remained in the ranks of homœopathists, and are now working as missionaries to persuade their friends to follow. 3. How the state of affairs is to be explained, let me say that the explanation is very simple, viz.: that homœopathic physicians are educated, and the people are becoming more enlightened, and the refined are able to grasp the idea as defined in the law of cure.

When they are told that if crude medicines are taken into the human system in large quantities, in health, they produce certain symptoms which are called physiological; and when similar symptoms are found in pathological conditions, and those medicines are given in the smallest dose possible so as

not to aggravate the case, or produce physiological symptoms, then the pathological symptoms and conditions are removed, and the patient is said to be cured homœopathically.

According to my understanding of the treatment the practitioner is not confined simply to infinitesimal doses, but his own experience must be his guide; and he may give the crude drug in small doses, in any given case, when he thinks proper, if it is homœopathic to the pathological symptoms. They claim that homœopathy does not consist in the size of the dose of medicine, but the physiological action of medicines and the pathological symptoms, constitute their guide in therapeutics.

Now, whether this be true or not, we know that they cure their patients quickly and safely with small doses of tasteless medicines, and the people are delighted with the system of treatment.

A. GIVEN.

Louisville, Ky., 1403 Jefferson St.,

July 15th, 1887.

[To give courteous hearing to an opponent is the first step in showing him his error. Then, too, a one-sided fight is not enlivening, and the discussion in these columns has so far been rather one-sided, albeit right-sided.]

EDITORS OF THE REPORTER.

NEWS AND MISCELLANY.

Western Pennsylvania Medical College.

This college has now a faculty of twenty-two professors and an equal number of adjunct teachers. The number of students graduated this year was twenty-two out of an attendance of sixty. The trustees have erected a substantial college building, adjoining the Western Pennsylvania Hospital, so as to facilitate clinical instruction.

The prospects of this college are good, and we hope it may be able to enforce a high standard and a three years' course, which latter is now optional, as in most American colleges.

Fever and Ague at Wyoming.

There is a great deal of fever and ague in Wyoming, close to the scene of the historic massacre. At the invitation of Dr. Knapp, of Wyoming, Dr. David Engleman, Dr. Benjamin Lee and Mr. Howard Murphy, of the State Board of Health, visited the village on July 22, to make an investigation.

For several years the inhabitants of Wyoming have been subject to these visitations of fever and ague, and this year the sickness is more aggravated than usual.

Small Medical Schools.

The *Indiana Medical Journal*, in an editorial entitled "The City Doctor," says:

"The country physician aspiring to city life may join with some of his brethren who know the ropes, rent, charter, elect trustees, issue catalogue, organize, lecture and be known as 'professor.' Rooms, \$200; outfit, \$100; diploma stone, \$100; permanent endowment fund for catalogue and graduating expenses, \$100. Ten students, if they pay, will be enough to foot the bill. It is not by any means necessary to have so many students as professors, and a board of trustees from the out towns may be had for the asking."

The same in Ohio. We now have sixteen medical colleges and more in view.—*Columbus Medical Journal*.

The Pasteur Commission.

The Commission appointed by the British Parliament to investigate Pasteur's method of treating rabies by inoculation, has just made a report which strongly endorses most of his claims. The report is signed by James Paget (Chairman), T. Lauder Brunton, George Fleming, Joseph Lister, Richard Quain, Henry E. Roscoe, T. Burdon Sander-son, and Victor Horsley (Secretary).

New York Law Concerning the Registration of Physicians.

The act to regulate the licensing and registration of physicians and surgeons, and to codify the medical laws of the State of New York, is now a law. The only opposition made to this act has come from those who believe that the power of healing by the laying-on of hands is likely to be diminished or impaired by the course of study required by the medical colleges. By this act, no person can be licensed or permitted to practice who has been convicted of a felony by any court of competent jurisdiction; and conviction of a felony cancels the license, if one has been granted. We are informed that there is now practising in New York one who has served three terms of imprisonment for criminal practice. The following offences are also punishable under the law: perjury, in false affidavit in registry; counterfeiting, buying, selling, and altering diplomas, or practising under counterfeited diplomas; or falsely personating another practitioner.—*Science*.

A New Obstetric Degree

Has been created by the University of Dublin, that of Bachelor of Obstetrics, B.A.O. This is the junior degree correlative to the M.A.O., for which a graduate must necessarily be a Master of Arts, whereas for the new degree it is sufficient that he shall be a Bachelor in Arts.

Charcot and Hypnotism.

In a letter addressed to Dr. Merlotti, an Italian physician, Professor Charcot alludes to the danger to morals and health which are likely to result from public exhibitions of hypnotism, or, as it used to be called, mesmerism. The induction of the hypnotic condition, says the professor, is by no means as inoffensive as we are asked to believe; it approximates so nearly to the hysterical neurosis that under such circumstances it may, like the latter, become freely contagious. If medicine in the cause of science has taken up this condition, its evocation should be restricted to the narrowest limits, and it ought never to be allowed in profane hands, capable of misusing it to the public detriment.

Can Doctors Practice Dentistry?

A case involving this point recently came up in New York, and was decided in the affirmative. A Dr. Bradford was charged with illegally practising dentistry. He showed that he was a legal physician, and the complaint was dismissed.

A Doctor in Trouble.

Before United States Commissioner Edmunds, in Philadelphia, a hearing was recently given Dr. Samuel Miller upon the charge of using the mails for the carrying on of a fraudulent business. Inspector Barrett testified to having received complaints that upon the receipt of postal cards issued by the defendant giving the titles of medical books, with the prices attached, orders had been given for books, money being sent at the same time for them. He had informed the defendant that unless the complaints ceased he (Miller) would get himself into trouble. He directed the defendant's attention to the fact that the postal laws had been violated. The excuses given by the accused for failing to send the books when ordered, were either that he had been disappointed by the book-binder or the printer.

A number of letters from physicians in various parts of the country were exhibited, complaining either of not getting the books they ordered or only a portion of them.

Items.

—In Berlin, twelve veterinary surgeons are employed to stamp meat before slaughter, and forty microscopists are continually employed to examine meat exposed for sale, beside one hundred experts, twenty-six of whom are women, who are also employed in protecting the people against the sale of unwholesome meat.

—It is stated that a lotion of weak carbolic acid, sponged over the body once or twice daily, affords an efficient means of protecting young children against the bites of gnats and other small insects.

—The *Chicago Medical Times* has the following, and we are not sure that it is not about right: "Country physicians save more money every year, on an average, than city doctors. Their minds are free, their consciences easy, and their pocket-books flush, even if they cannot 'put on style' and hold prominent college and government positions."

—The French Academy of Sciences has been authorized to accept a bequest of 40,000f., made by M. Martin-Damourette, for the purpose of founding a yearly or biennial prize to be awarded for researches on therapeutic physiology.

There have been no changes in the Medical Corps of the Navy for the week ending Aug. 6, 1887.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from July 31, 1887, to Aug. 6, 1887:

Col. Chas. Sutherland, Surgeon, leave of absence extended one month. S. O. 175, A. G. O., July 29, 1887.

Major B. E. Fryer, Surgeon, relieved from further duty at Ft. Lowell, Ariz. S. O. 176, A. G. O., Aug. 1, 1887.

Major Harvey E. Brown, Surgeon, relieved from duty in Dept. Mo., and ordered to Jackson Bks., La., for duty at that port. S. O. 174, A. G. O., July 29, 1887.

Capt. John de B. W. Gardiner, Asst. Surgeon, granted leave of absence for one year on surgeon's certificate of disability. S. O. 177, A. G. O., Aug. 2, 1887.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for two weeks, ended Aug. 6, 1887.

Fairfax Irwin, Passed Asst. Surgeon, to inspect unserviceable property at New York Marine Hospital, Aug. 6, 1887.

H. R. Carter, Passed Asst. Surgeon, granted leave of absence for six days, Aug. 1, 1887.

A. D. Bevan, Passed Asst. Surgeon, granted leave of absence for ten days, Aug. 5, 1887.

Seaton Norman, Assistant Surgeon, granted leave of absence for four days on account of sickness. Aug. 5, 1887.

ALIMENTATION IN PHTHISIS.

BY SOLOMON SOLIS COHEN, A. M., M. D., PHILA.

After all is said and done, the most important feature in the management of a case of phthisis, is the maintenance of nutrition. We must endeavor not alone to balance current waste by repair, but also to make up previous waste by an excess of aliment above daily needs. In order to enable this excess of aliment to be appropriated and utilized, our hygienic and medicinal treatment must aim to put the digestive tract in proper condition, to remove as far as possible any obstacle to the elaboration and assimilation of the products of digestion, and to favor the speedy elimination of all effete materials. To do this there must be a proper regulation of rest and of exercise; respiration must be aided by gymnastic exercises, forced respiration, inhalation of compressed air, and similar measures; and certain symptomatic and antiseptic medication must be instituted, which in the present article is not intended to be discussed. Independently of drugs, however, the stomach and intestinal canal may often be put in proper condition for digestion and absorption of the materials furnished by systematic drinking of hot water (half pint to one pint an hour before meals), or by what is known as *lavage*, i. e., washing the stomach. The aliments from which the greatest food is derived by the greatest number of patients are pre-eminently the animal members of the nitrogenous

group, and of these, more especially, beef. It can be given cooked or raw, as may be found most palatable or most useful. It may simply be chopped finely and seasoned with pepper and salt, or various condiments; or it may be chopped finely, seasoned and made into cakes, which are then lightly browned on the gridiron; or it may be roasted or broiled, rare. It should never be well-done. Next to beef comes milk, then eggs, when the patient can digest them; mutton, poultry, fish and green vegetables, especially those of the leguminous group. Bread should be taken in moderation, and gluten bread, or that made from the whole wheat, is preferable. Farinaceous and starchy foods in general need not be avoided unless the form of indigestion present demands it, but they should be distinctly secondary to the nitrogenous materials; and the carbohydrates necessary should be sought in oils and fats, preferably from the animal kingdom. Inunctions with oil sometimes seem of service. The oil of gaultheria often furnishes an agreeable odor to disguise that of the oil employed for inunction. Sweetbreads are often valuable, both as aids to digestion and as food. Powders of beef as prepared by various pharmacists, and especially those that are predigested, such as Reed & Carnrick's Beef Peptonoids, are of great value, and are best given between meals, in milk. Of this preparation, I am in the habit of beginning with one teaspoonful in about four tablespoonfuls of warm milk, four times daily, and increasing the dose to a tablespoonful, as I find it well borne. Some patients prefer to take it in soup and at meal times; some

prefer it in cold milk, others in warm or cold water. It may advantageously be added to milk-punch or egg-nog. Nutritious soups of all kinds are of use, to vary the diet. To furnish the necessary fatty elements of food, oil dressings of salads, etc., will be advantageous. Butter should be used freely; and this use of it will often be found to avert the necessity of administering cod-liver oil. In fact, my own resort to cod-liver oil is extremely limited. Cream, when well digested, is of great service, and a tumblerful on retiring, with or without alcohol, will often be found to promote sleep, as well as to be of nutritive value. Alcohol has a positive nutritive value, especially in cases characterized by high temperature. The dosage and frequency must be regulated by circumstances. Usually a tumblerful of milk punch night and morning (with from half an ounce to an ounce or more of good whisky or good brandy in each tumblerful) will suffice. I have known, however, in two or three exceptional cases as much as a pint of whisky daily (in divided doses) to be taken for a limited time, with benefit. A claret glass of good Burgundy wine may be taken with the principal meal of the day. Wine of coca, if a reliable article is obtained, is often of benefit; from one to four or more wine glasses per diem being taken, according to the preparation and the indications. Various preparations of malt are often useful.

A phthisical patient should rarely go without food longer than three hours, and never for more than four hours, except during sleep. Three good set meals will suffice; but in the intervals the milk, milk-punch, cream, cream-punch, soup, beef-powder, beef-peptonoids, etc., should be taken. The physicians orders upon this point must be imperative, and the hours and quantities, as well as kinds of food, must be precisely stated. Of great importance is the glass of cream, or similar article, just before retiring; and when the patient goes to bed early, as he ought to, a glass of milk or of wine, according to circumstances, should be taken if he wakes during the night or early morning.

It is best to feed by natural methods, and when a sufficient quantity of food cannot be taken at one time, to increase the frequency of meals, rather than to overburden the digestive apparatus. In such cases, too, the condensed and predigested foods must be largely used. When milk is not well borne, it should be peptonized. Milk is sometimes best taken hot, sometimes cold. I know of no indication but experience. The manner

of drinking it is often important. Patients frequently gulp a glassful down, precipitating it in an unfit state upon a disordered stomach, in which case a hard and tough coagulum is likely to form, which is digested with difficulty if at all. They should be directed to take it slightly warmed if possible, say to blood-heat, and to sip it slowly, so as to thoroughly incorporate it with the saliva. A little lime-water may be added if necessary; but usually the slow sipping, consuming ten minutes to a tumblerful of milk, will alone do away with all the bad results attributed to the "disagreement" of the milk.

I have seen astonishing improvement follow forced feeding by the means of the cesophageal tube (gavage) after Debove's method.

Two patients under my own care increased in weight nearly a pound *per diem*, in one case for two weeks (9 pounds increase, 6 pounds in the first week), and in the other for five days (4½ pounds increase;) but their repugnance to the method could not be overcome and it was perforce abandoned. Less rapid but equally steady gains may be obtained from superalimentation by less distasteful methods. Nevertheless when sufficient food cannot be taken in the ordinary manner, the tube should be promptly and unhesitatingly employed. In such cases, too, when practicable, a combination of the "rest treatment" with the gavage, would probably be most beneficial.

SUMMARY OF THE DIAGNOSIS, PATHOLOGY AND TREATMENT OF PERFORATION OF THE APPENDIX VERMIFORMIS.*

BY J. M. F. GASTON, M.D., ATLANTA, GA.

The practical deductions from this inquiry, in regard to the concomitants of perforation of the appendix vermiformis, may be included under the following heads:

1. The primary disorder is dependent upon a local irritant, either mechanical, chemical or vital, inducing ulceration and disintegration at some point in its walls.
2. The modification in the tissues of adjacent parts depends upon the presence of a toxic exudation from its cavity, that ultimately leads to disorganization of structure.
3. Extension of the degenerating process depends upon the formation of the structures

*Abstract of a paper read before the American Medical Association.

with the fæcal matter, but may result from suppuration, or the automatic propagation of inflammation from one part to another.

4. Agglutination between the layers of peritoneum may shut in purulent accumulation, and thus limit the inflammatory action to a circumscribed area, so as to assume the nature of an abscess in that locality.

5. General peritonitis may be accompanied by extensive adhesions of the adjacent serous membranes, and followed by vital prostration and collapse, calling for the knife.

6. Septicæmia may occur from absorption of septic matter, independent of suppuration, and associated with a low form of fever, which ought to be treated by antiseptics and irrigation of the abdominal cavity by hot water.

7. When there are sufficient indications of perforation in the general symptoms, with pain and tenderness on pressure over the cæcal region, without signs of fluctuation, an exploratory puncture below the ilio-cæcal junction is warranted.

8. If there are reasonable grounds to believe that pus is present, or there is extravasation of fæcal matter, whether from the perforation of the cæcum or appendix, a free incision above Poupart's ligament should be carried down to those parts and drainage kept up afterwards.

9. In perforation of the appendix, associated with general peritonitis, an incision in the linea alba affords the best prospect of washing all the parts involved, and should be accompanied by thorough cleansing of the abdominal cavity, and especially the ilio-cæcal region.

10. The most efficient means of closing an opening in the cæcum is by Lember suture, while one in the appendix demands excision and ligation.

11. When perforation is suspected, washing out the abdomen, by the use of a syringe and two tubes, will assist in the diagnosis and treatment.

12. An early operation, with a doubtful diagnosis of perforation of the appendix, lessens the liability for a confirmation of it by a necropsy, and hence no time should be lost in awaiting developments.

—The Austrian government has appointed a committee to revise the pharmacopœia of that country, in order to bring it up to the level of the recent advances in science. The last (sixth) edition of the work was published in 1869.

THE THERAPEUTICS OF STIMULANTS.

BY REBECCA C. HALLOWELL, M.D.
OF ATLANTIC CITY, NEW JERSEY.

Read before the Atlantic County Medical Society,
May 4th, 1887.

A notable revolution in the treatment and cure of disease seems threatening the permanence of old theories and practices. Weighed in the balance of new investigations, errors are being discovered and misconceptions corrected. By hygienic measures and careful regimen exclusively, abundant proofs are constantly being reported of the curability of disease. Instructors are making much of the basic facts of sanitation, and people in all classes are considering more and more ways and means promotive of health and pure living without physic. Harvard is looking forward to a Chair of Preventive Medicine, and the Woman's Medical College of Pennsylvania, will in the near future establish this branch; plans being now on foot for the purpose of raising the necessary funds. "The Chair to include" (so the announcement reads) "the scientific investigation of the conditions under which diseases originate and thrive; the thorough demonstration and practical application of the principles of hygiene, personal, domestic and public, and to bring this knowledge to bear upon the environment of individuals, classes and communities for the correction of conditions prejudicial to health."

The people are questioning as they never did before, and demanding to know why intoxicants are indispensable. It is said that the great and good men of the land, the leaders of public opinion, gravely study this intricate problem of the supposed necessity for alcoholic medication. With a higher intelligence daily rising to confront and question, it seems but the part of policy to say nothing of wisdom, not to dismiss with indifference and ridicule a subject which so profoundly disturbs the minds of the laity. Though our art still endeavors to hedge itself about with the bristling bayonets of exclusiveness, still resents questioning and prying eyes, and with mild scorn smiles at dictation and suggestion from the unanointed, yet each year the latter press closer to the sacred doors. England's people waited for twenty years, while her mentors tried to prove the boasted benefits of the cruel, immoral regulation laws; but at last the storm came, and last year the statute books were cleansed by

repealing them, and "rightly repealed," a brave gentleman said at the Sanitary Congress in England, last fall.

Dr. Richardson said to a class of students, "You must either stand above the masses or fall beneath them; sit with them you cannot. You must equip yourselves to become the leaders and teachers on all subjects that relate to their life and health." He further says, "All educated people are becoming scholars in natural science, physiological scholars especially, to whom two parts out of four of our art and mystery are revealed. One part out of four is preventive and personal, that is to say hygienic or sanative—a part of medicine which has become the property of all classes." Discussion seems to be in the very air. Surely it is the special prerogative of the physician to teach and lead not only in the sanitary conditions of the people, but in whatever has to do with the elevation of the race and the "great interests which are shaping its destinies."

In the light of the overwhelming testimony of the most distinguished practitioners of Europe, and a rapidly growing number in our own country, the intricacy of the question of the uses of alcohol in medicine becomes more apparent.

When entering upon the study of medicine the earnest, conscientious student, even if disposed to doubt the many virtues claimed for alcoholics, believes that to be loyal to the sacred cause he has espoused, he must be ready to yield all preconceived notions or prejudices not strictly in accordance with science. Besides, if disposed to question, what time there was to select one, from the great armamentarium of remedies to pursue with special inquiry? There was no time nor place on a crowded curriculum to weigh the *moral* aspects and evils, which to day so seriously engage the thought of the sanitarian.

"But the subject is influencing medical practice in the treatment of disease," said the Medical Health Officer, at the opening of the Sanitary Congress, held at York, England, last autumn. "We are arriving at a very different opinion in relation to the necessity for alcoholics from that formerly held. I think there is scarcely a disease for which we used to think alcohol necessary, that now we cannot treat equally well or better without. The question has come to the front, and we should do all we can for it."

One writer says, "I should like to know how many physicians administer alcohol on scientific principles. It requires a strong mental effort to throw off prejudices and the

influence of appetite to take a purely scientific view of the use of alcohol."

The *Lancet* says: "The question is one for the scientific and thoughtful physician to discuss gravely, and medicine will not be without much authority, and let us repeat, responsibility, in its settlement."

The subject seems to be engaging more and more the serious thought of the most brilliant apostles of medicine. Dr. Pepper remarked in an address before the Medical Faculty of Maryland, "The rise of the so-called restorative medicine brought to a dangerous and absurd height the practice of indiscriminate stimulation and gorging in all forms of disease. The reaction against this extreme has set in. . . . The restoration of power can be accomplished by cautiously but thoroughly adapting the diet and hygiene to the altered state of nutrition, and thus having adjusted the physiological balance, direct remedies to actual conditions."

Dr. James Ridge, Physician to the London Temperance Hospital, says: "Hundreds of physicians order alcoholic liquors from habit, from ignorance of their real effects, from fashion, or from a desire to please, or not to offend their patients. Port wine is constantly being ordered when persons are recovering from various diseases; day by day they regain their strength, and the port wine gets all the credit of it, especially since each glass seems to diffuse a comfortable glow over the whole body. They forget that the process of recovery would have gone on without the port, and that hundreds and thousands of people do get well without it. They often ignore the fact that they are taking real tonics in addition. They are misled by the sensations which the alcohol causes; they do not know that it relaxes the blood-vessels instead of improving their tone; that it exhausts the heart by making it beat more rapidly to no profit. Hence, convalescence is actually more prolonged than it would otherwise be. Gentle exercise, regulated baths, good food, balmy sleep, are the true restoratives of the exhausted system, and no jugglery with alcohol can produce the desired effect. It is by its sedative action that it has obtained its position in public opinion. The relief that can be obtained by alcohol is delusive and dangerous."

These are bold assertions, unless the writer can substantiate them with actual proofs. It has been pertinently said, "Alcoholics are far more agreeable to most people than other remedies. The taste and exhilarating effects are pleasant. The patient comes with the

inquiry whether a little wine will not be advisable. The physician frequently yields, because it pleases the patient, when he does not doubt that some other remedy would be preferable. He is not besieged in this way to use any other remedy. No one comes to inquire whether it would be best for him to go on with strychnine or belladonna, but this fishing for an alcholic prescription is of almost daily occurrence, and is far too frequently successful." And he adds: "Many a man has shielded himself behind a physician's prescription."

A doctor's wife, a lady of rare intelligence, once said to me: "Doctors are more to blame than they are aware for this love of tipping. They do not like to worry with tired, nervous people, and they take the easiest and most pleasant way out of the difficulty by ordering one of the many so-called tonics, for instance Johann Hoff's extract of malt, with its more than twenty per cent. of alcohol; or beef, wine and iron, which is so welcome on account of its sherry."

I am reminded here of a case I had several years ago. A lovely, fresh-looking young woman, the mother of several beautiful children, a home-loving mother and faithful wife, devoted to her children, was beginning to run down in health, and as a pleasant tonic I ordered beef, wine and iron. She said, "Doctor, that is delightful medicine. I am glad when the time comes around to take it," and her eyes grew expressive. Two or three years later it was whispered to me that the lady indulged to intoxication in beers and brandy. And later on bills for whisky and brandy were alarming her husband, and causing unhappiness, for there were times when she was unfitted to care for home duties. I afterward learned that her father had been a drinking man, and she had inherited her taste from him. The ugly thought shot into my mind, did I awaken this by my beef, wine and iron? It was certainly not a pleasant reflection,—inherited appetite only waiting for the propitious opportunity to come to the front and take dominion.

Dr. R. Greene, in a paper read before a Boston medical society, said: "The laws of descent, by which depraved appetites are transmitted, are but little understood, and yet nothing can be more absurd than to suppose that physical deformity and debased mental qualities can be the result of sound physical health and normal conditions of mind. An inherited appetite for liquors may lie dormant for years, without giving the least indication of its presence; but let

alcoholic liquors be taken even under the prescription of the physician, and the appetite, hitherto dormant, may be aroused and incited, and become difficult to control. We are largely the product of the past; our physical and mental conditions are in a great measure woven for us."

Statistics are ugly things when they are on the wrong side. Some medical writers seem to enjoy figures, and are forever drawing aside the veil that hides the scum of the back-yard of the nation, and in grim fashion pointing to the lunatics, idiots and monstrosities, which they assure us are the product of drunken ancestry, and in persistent tones say normal conditions never produce abnormal results, and to disprove this statement would be to dethrone God and give the government over to chance. There are today hundreds of thousands of parents addicted to the use of liquors, who would scorn the idea of being considered intemperate, and yet these very people are inevitably perpetuating weakness and entailing upon children and grandchildren an endless heritage of moral, mental and physical misery. Not only are physical deformities and predispositions to the taste of alcoholic liquors transmitted, but the frenzied excitement, nervous and demoniacal disposition of inebriate parents are often perpetuated as characteristics in their offspring, urging them into crime and degradation.

Hawthorne says: "We assume that faults and frailties are more readily and persistently reproduced than virtues, since the former belong to man's nature, as distinguished from that self-affected modification of his nature which we call character. Nature is passive, and character is active; and activity is more apt than passivity to be original and peculiar."

Dr. Greene further said in his address: "It is upon the members of the medical profession, and the exceptional laws which it has always demanded, that the whole liquor fraternity depends, more than upon anything else, to screen it from the opprobrium and just punishment for the evils which the traffic exerts upon society."

And how they do propitiate the doctors! One day there came to me by mail a budget in gorgeous array of coloring, setting forth the unrivaled medicinal virtues of rare old champagne; the wines of Burgundy, Moselle and Rhine; the Hungarian, with its *peculiar* medicinal qualities, and the sherry and the port, with a long list of virtues, so delicious to the senses, that one is tempted to believe that half the joy of life is lost when dis-

carding these "nutty," "fruity," "golden," "mellow," "delicate," "very old" and youth-giving delights. So rhythmically and musically did the appetizing adjectives run on that one's sense of the poetical was rudely jarred, and ugly pictures loomed up, when the list ended in the suggestive names: "Fish House Punch" and "Whisky Cock-tails!"

"No doubt," said a speaker at the Sanitary Congress, "alcohol may be a good rough-and-ready remedy, when you do not happen to have the pharmacopœia at your back; but where you have, you will find something that will do what alcohol cannot do. If you want a diffusible stimulant you will find something far better than alcohol. If you want something to quiet the stomach, you will find something better than alcohol."

When Dr. Nathan S. Davis, of Chicago, was entertained at the Brighton breakfast last summer by the British Association, he was called upon to speak, and said:

"The medical profession must face this matter of alcohol, and accept and act upon that responsibility. They must be the educators that are to teach the people that instead of wine and beer and ale and whisky being necessary for man, they are simply anæsthetics and absolutely poisonous, calculated to shorten the duration of human life, and to diminish every interest that man has in the world." Further on he said: "While medical advisers go to your fireside and educate your children by their very language into the belief in alcohol, that every fainting is to be propped up by it, and every cold is to be mitigated by it everywhere; that alcohol is the one agent that is to cure all the ills that ever sprang from the box of Pandora—as long as this is done by the medical profession it is in vain that you teach simply morality."

The "Lancet," in referring to this speech, said: "Dr. Davis's disparagement and denunciation were absolute and unconditional. We are tempted to ask if the doctor's indictment is the whole truth, if alcohol has no redeeming quality. Admitting that it does infinite harm, does it do no good? Does it prevent no evil? Can the able physicians who recognize its virtues be all mistaken?"

"What do we know about intoxicants?" asks Dr. Norman Kerr, President of the Society for the Study and Cure of Inebriety.

"Let us interrogate science; science is simply knowledge. She will tell us the exact truth unbiased by any consideration as to

the kind of answer we should like to have from her. We designate alcohol as a poison in the same manner as we designate chloroform or ether. If they are poisons, so is it. If they are not, it is not."

Turning to Davis' *Lectures on the Principles and Practice of Medicine*, a volume of nine hundred pages, on the methods and results of treating all varieties of disease without the administration of any kinds of alcoholics, we gather in the closing lecture in the Practitioners' Course for 1884, the following: "When the chemico-physiological school of investigation with Baron Liebig at its head, developed the fact that all alimentary substances were capable of being arranged into two classes, the nitrogenous and carbonaceous, the theoretical idea was adopted that the former were appropriated to tissue nourishment, and the latter uniting with oxygen by a species of combustion resulting in the development of heat and carbonic acid, were respiratory foods. Alcohol being rich in carbon and hydrogen was at once assigned a place at the head of the list of respiratory foods and of supporters of animal heat. When taken into the living system it was supposed to unite rapidly with the oxygen received through the lungs evolving heat, and leaving as resultants carbonic acid gas and water; in this way its supposed heating and stimulating effects were explained. The simplicity of the explanation, coupled with the high authority of Liebig, caused it to be universally accepted, although resting on a purely theoretical basis, without a single experimental fact for its support. Dr. Prout, of London, by direct experiment, proved the fallacy of the evolution of heat theory, and others followed. Dr. Percy found that alcohol taken in a dilute form into the stomach was carried with the blood into all the organs and structures of the body without change of composition, and that its presence could be easily detected by the proper chemical tests. The school of investigation still believing that alcohol being a hydro-carbon, must necessarily be used for maintaining temperature and respiration, suggested that its union with oxygen might result in forming acetic instead of carbonic acid, and the popular belief was sustained that alcoholics were capable of increasing both the temperature and strength of the human body." In the meantime experimentation went on. Dr. Böcker, of Germany, by a very careful series of experiments, proved that the presence of alcohol in the living system actually diminished the eliminations of effete matter, and consequently that its presence must retard those

molecular changes by which nutrition, secretion and elimination are effected. Dr. Davis proved by an extensive series of experiments that during the active period of digestion, after taking any ordinary food whether nitrogenous or carbonaceous, the temperature of the body is always increased, but after taking alcohol in the form of either fermented or distilled drinks, the temperature begins to fall within a half hour, and continues to decrease for two or three hours. Later on Lallemand and Perrin proved conclusively that alcohol when taken into the stomach was not only absorbed and carried into every organ and tissue of the body, but also that it was eliminated as alcohol, unchanged, chemically, from the lungs, skin and kidneys. Another French scientist, Duray, in his work on the action of alcohol and anæsthetics in the organism, gives the same testimony. Dr. Prout's experiments were repeated, and his results were confirmed by Sandras and Bouchardet of France; Hammond, Davis, and others of this country. Böcker's experiments were carefully repeated by Anstie and Hammond. Dr. Davis repeated his experiments on heat, and these were confirmed by a large number of observers, among whom were Richardson, Anstie and Hammond. Dr. Davis says further in his valuable work: "It is conceded by all investigators that when alcoholic liquors are taken into the stomach, the alcohol is rapidly absorbed into the blood, circulates with it throughout all the tissues of the body, and may be detected in the form of alcohol both in the blood and in the structures of the various organs. All agree also that it is eliminated through the various eliminating structures."

These facts, when observed in regard to the behavior of any other substance, are regarded as amply sufficient to prove that the substance so acting is not alimentary in its nature, but foreign to the system. But so strong is the predisposition to find some important use for alcohol in the human system, caused by customs and habits of thought through many generations, that the most vigorous tests and calculations have been made to ascertain whether some part at least of the alcohol taken might not be retained, and, if not used directly for nutrition of the tissues, certainly converted into some kind of force or energy. The experiments of Lallemand and others, in reference to the elimination of alcohol, have been abundantly confirmed, except the claim that the amount eliminated is not equal to the whole quantity taken. For a long time it was claimed

that the retained portion underwent oxydation and evolved heat. But this was at last fully demonstrated by direct application of the thermometer to be erroneous. It was then assumed, by Dr. Parkes and Count Wallowicz, that its consumption resulted in the evolution of nerve force. But here, again, the crucial test of direct experiment soon showed that so far as the motor and sensory nerve and muscular functions are concerned, both were diminished in direct ratio to the quantity of alcohol taken. Dr. Davis emphatically asserts that the propositions advanced are as well established as any facts in the domain of physiology, or in the whole field of natural science; and they point with all the clearness and force of a mathematical demonstration to the conclusion that alcohol is in no sense food, neither furnishing material for the tissues nor fuel for combustion, nor yet generating either nervous or muscular force. Its positive effects are simply those of an anæsthetic and organic sedative. The retained alcohol, that is not eliminated, is held simply by a strong affinity for the albuminous constituents of the blood and tissues, retarding by its presence the natural affinities and movements of such constituents, and is detached by the slow process of disintegration. It is exactly this retained alcohol that causes in the habitual, moderate drinker those slow but certain deteriorations of structure, described under the head of "fatty and atheromatous."

Lately I have received several letters in reference to the attitude of the profession as a class in this country on this question of alcohol as a medicinal agent, which so profoundly disturbs the British medical mind. One, a prominent clinical teacher, writes: "My belief is as heretofore. I advise alcohol as a fortifier and bridge in acute diseases, when sufficient food cannot be taken to meet the body needs. I have as much right to that belief as to any other clinical fact which I have witnessed."

Another, from a gentleman of wide acquaintance in the medical world, distinguished as a surgeon and a teacher of young men. Being of the conservative school, and not fond of innovations of any sort, I was desirous to have his opinion. After expressing strong condemnation of the stupidity of the class of people who convert any good into evil, he adds: "I know of no medical men in this country who are at all active or even markedly interested in the question. In prescribing, however, a judicious physician considers the habits and weaknesses of the patient prescribed for."

Dr. Davis seems to hold a different opinion in regard to the interest of the profession in this country, for he declared before the British Association, "when I am at home hardly a week passes but some one writes from different parts of the northwest country who has found by experience and actual test that he does not need alcohol in the treatment of disease. If these were summoned together, there would be near a thousand, some of them of high standing"; and he said further, "step by step the progress of science has nullified every theory on which the physician administers alcohol. Every position taken has been disproved, until it is narrowed down to this: acute diseases where it is supposed there is danger from extreme weakness. In typhoid fever it is resorted to as a tonic, and the weaker the patient the larger should be the dose to prop up the circulation. I have seen the experiment tested again and again, with my finger on the pulse, watching my patients at intervals, and I have never yet found any evidence that alcohol increases the force of the heart one iota. The result of absolute test and careful experiment have shown that just in proportion to the amount of alcohol mingled with the blood, just in the same proportion the heart's force was diminished, and the amount of blood delivered from the heart was diminished and at no stage increased from the beginning to the end. At no stage was there increased power until, as the alcohol was increased, the heart's action stopped in paralysis. And with my own countryman, Prof. Martin, of the Johns Hopkins' University, who had every requisite that science could invent to secure accuracy in learning exactly the amount of alcohol in the blood, at each successive stage of increase, from the slightest to the full amount that was fatal to the heart's action, the test proved just the same: that in exact proportion to the amount of alcohol added the power was diminished, and that diminution was arrived at in a very marked degree by mixing only two and one-half parts of alcohol to 10,000 of the blood; that is, estimating a certain quantity of blood in the average man, it would require the presence of half an ounce of alcohol to a good ordinary adult man—absorbed and diffused in the blood—to be sufficient, according to those experiments, to make a very marked and decided diminution in the cardiac powers and in efficiency in circulating the blood, thereby showing as clearly as possible that, instead of being a cardiac tonic, it is an absolute cardiac paralyzant; Martin's results were that simple increase in the relative pro-

portion of the blood, as in the other, stopped the heart in diastole—utter paralysis. And even before these experiments, Prof. Anstie, who investigated narcotics, anæsthetics, and stimulants, in his last edition, said: 'It must be conceded, from all experiments and observations, that instead of there being a stage at which alcohol produced an increased action of the heart, the paralyzing effect coming afterwards, that apparent excitement and exhilaration was only the first step of paralysis.' And further on he says: 'I have come to one distinct conclusion, the importance of which appears to be very great, namely, that, as in the case of chloroform and ether, the symptoms so commonly described as evidence of excitement depend on a stimulation of the nervous system preliminary to the occurrence of narcosis, and are in reality an essential part of the narcotic, that is, the paralytic phenomena.' Dr. Davis continued: "Hence, I assume that alcohol neither strengthens, nor nourishes, nor sustains the heart's action, but diminishes it. You will see that Dr. Parkes, one of your own countrymen, demonstrated by his figures that the heart under the influence of alcohol increases the amount of work done sufficient to be equivalent to lifting a ton weight a certain height in a day. He figured it all out mathematically. Pray let me ask you to look critically at those figures. They are founded entirely on the fact that, under the influence of alcohol, the heart is increased in the frequency of its beats, by a certain number in a minute. He has taken as the basis of his figures, that because the heart acts four or five times a minute faster on the average, under the influence of alcohol, it does so much more work. Now, if mere frequency were a cause of more work, the basis would be right; but does not every medical man I address know that, instead of that being a proper foundation, the more weak the heart gets, as a rule, the more frequent are its beats? that instead of increased contractions of the heart being a measure of the efficiency of the power, and the amount of work done, it is rather a pathological indication that its power is diminished? and this is in direct accordance with the results of other observation. Instead of it proving the heart does more work, it simply proves that its physiological power is disturbed, and unquestionably the paralyzing influence upon the vaso-motor nerves, diminishing the circulation in the capillaries, presents a barrier which is the immediate prompter to the heart acting to try to overcome the obstacle; and, if he could have done as Martin and the other experimenters did—measure the

actual amount of the delivery of the blood from the heart, so as to measure its power—he would have found that, instead of doing more work, it does less. Its quickness is an evidence of its embarrassment. I was taught, like all others, to use alcohol as a tonic. When convalescence came, a little wine each day, or some bitter herb in whiskey, was calculated to hasten recovery and promote strength. But some of my patients refused because they were teetotalers, and I soon found that they recovered strength sooner without it, and that there was less tendency to relapse than in the cases of those who continued its use. Here was the first step in progress, and consequently I came soon to abandon it as a tonic, as I found it of no value. On the contrary, while the patient took it for the first few days or nights, the anæsthetic effect diminished their weakness, and there lies the delusion. One of the curiosities in my mind in regard to alcohol is the delusion it has upon the world. The words “Wine is a mocker, and whosoever is deceived thereby is not wise,” were put in the good old book for a purpose. Mocker! What does a little alcohol do, such as would be considered a tonic? It is just like ether, or chloroform, or any other anæsthetic. It dulls the cerebral hemispheres, and so removes for the time being the consciousness of aches and pains and weariness, and leaves the individual at ease. But a little further, and it diminishes these sensations still more, and the body begins to feel light and hardly conscious of its own weight. In this stage there frequently comes the disposition to dance or sing, and the tongue gets loose. Now the world calls that evidence of excitement, evidence of stimulus; but instead of accepting that verdict, analyze it, and alcohol is found to be exactly parallel with every other anæsthetic. The patient goes through exactly the same stages as in chloroform anæsthesia. But where is the surgeon who supposes he is stimulating or invigorating his patient? It is only the transition from the first beginning of diminished consciousness. Next he begins to lose his sense of propriety, and talk as he would not were he free from that influence; and that same influence causes him to say that it protects him from the cold. How long the ages have been in which the belief has prevailed that, if you are going out into the cold, you cannot stand it without having something to warm you. And they would be ready to testify before a court of justice that it did warm them. How many thousands of our profession have been giving it, are giving it to-day, when the feet are cold,

to help to warm the patient, and yet the thermometer tells accurately, step by step, that from thirty minutes after it is taken to the end of its influence the temperature is diminished. The patient would testify the contrary. Why? Simply for the reason that the anæsthetic effect diminishes his consciousness of whether it is cold or not. The laborer, dripping in perspiration in July, takes it, and tells you “he cannot stand the heat without it,” exactly reversing the case. It warmed him in January; it cools him in July. Just the same with the good mother when nursing; she supposes that nursing pulls upon her strength and thins her blood, and she takes a little wine and beer at every meal to keep up her strength and to increase the flow of milk; and here she suffers exactly the same delusion as the laboring man. With the anæsthetic effect of the alcohol, she does not realize the sense of weariness in her muscles, and she says “it is the only thing that keeps me up;” but every one of these mothers, within four to six weeks of its use, when they stop and compare their condition with what it was when they began, know their last state is worse than their first. The alcohol has been a positive detriment. Its presence in the blood diminishes the absorption of oxygen in the air cells of the lungs, as was long since proved. It lessens the exhalations of the waste carbonic acid, keeps the blood with an excess of carbonic acid, which is itself a further anæsthetic, and in the course of a few weeks the beer comes to supplant the appetite for food, and she tries to live upon it instead of digestible food, material that can make flesh and blood.”

Just here permit me to refer to the history of the case of a lady, given to me lately, which I thought might be triumphantly claimed on the alcohol side. This lady had been a great sufferer from “nervous dyspepsia.” She is the wife of a physician, and was attended by a prominent gentleman of Philadelphia. There was great emaciation, extreme debility, and chronic diarrhœa, and not the smallest quantity of food could be retained. Every remedy that could be thought of had been tried but failed. At last a friend induced her to try small doses of claret. She did so, and in a short time was able to take food in small quantities. The claret was very unpleasant to her, and as time went on grew more and more distasteful, but she determined to persevere, and finally digestion was entirely restored, and when I saw her she was the picture of health. As I had commenced to study the

effects of alcohol I was greatly interested in this case, and wished to know Dr. Davis's opinion, for I thought I had surely scored *one* for alcohol. The following is an extract from his letter: "I presume the case you speak of was really one of simple hyperæsthesia of the gastric and intestinal mucous membrane, and was relieved by the anæsthetic effect of the small doses of alcohol in the claret, and might have been relieved just as certainly and as quickly by the judicious administration of small doses of any one or half dozen combinations of anæsthetic and soothing antiseptic remedies taken immediately before swallowing doses of the simplest kinds of nourishment. At least I have never found *one* of the kind that I did not succeed in relieving without any kind of wine whatever."

Dr. Sinclair, of Belfast, says: "A consideration of the influence of alcohol on the system which does not take into account its effect on the heart, is not unlike a representation of Hamlet with the Prince of Denmark left out." And he adds: "What do we think of the value of any drug as a dietetic agent that leaves out of consideration the effects on other organs besides the stomach? What should we think of any conclusion drawn from the action of digitalis that left out its effect on the heart? And yet a distinguished writer has stated: 'I consider the stimulating action on the heart to be one of the most important properties of alcohol.'" Dr. Sinclair goes on: "A powerful action of the heart which causes the dilatation of the capillary system, caused by paralysis of the vaso-motor nerves, produces an increased flow of blood to the different organs of the body. Thus, when we take alcohol with food, at a time when we specially require for the process of digestion freedom from excitement, and less, rather than more, blood to the brain, we produce by this agent a congestion of, or an increased flow of blood to the brain, and we further increase the excitement by stimulating the heart."

Parkes, in his "Manual of Practical Hygiene," says: "Alcohol would be a most dangerous agent if it were not for the yielding of the vessels produced by paralysis of the vaso-motor nerves, the strong wave from the strongly acting heart would break the vessels, or the heart would not be properly emptied of the blood during the contraction. It seems likely, therefore, that there must be danger in the use of alcohol when the arteries become rigid in advancing age, if the heart is then susceptible to the action of it."

This hardly agrees with the old saying that "wine is the milk of old age."

Dr. Richardson says: "A faint heart that can be systematically restored by resort to alcohol is a diseased heart; of this I am as certain as I am of the animal mechanism;" and he goes on further: "I can have no object in defending this question, except in my solemn convictions of its importance as one of the basic facts of sanitation, and as such that we should give it our support. For my own part I have no kind of prejudice on the matter. To me the phenomena of life present themselves so entirely in the experimental form, I can harbor no prejudice, can find no time to encourage one. I look for evidence and having found that in nature, am led by it. I wish for no professional brother to believe it because I say a thing bearing on the question, though my studies have been longer than his, but I would invoke his honest judgment. It often occurs in men of science to look only on the side of the question in which they have been educated. One medical man has stated authoritatively and officially with regard to alcohol that it is a 'food, a stimulant and a sedative.' I want the profession to take the other side and analyze such a statement—to consider these three words and see how they apply as used. To say them of any one substance, seems to my mind to be altogether illogical and out of the question. I have been studying as a student again, the works of the masters in my profession on the degenerations to which the body is subject. Without the slightest selection I have been seeking the authorities on the causes of these degenerations. I take up the works of those who are simply pathologists and I find there is nothing so striking in all that history as the circumstantial testimony which these men bear to this one agent alcohol, in the production of these degenerations; other agents are referred to only accidentally but on questions of pathology, this has an all-pervading influence. By consensus of opinion you find these men writing down a series of degenerations springing from that one cause which put together would make a volume of the largest kind." He further records as a matter of personal history: "I had no thought of alcohol except as a food, a generation of force and fortifier in mental and bodily fatigue, but was asked to study the action of alcohol along with a whole series of chemical bodies, and to investigate their bearing in relation to each other. So I took the alcohol from the shelf, as I might any other chemical, and experimented over

a lengthened period and the results were invariable—neither ‘food, fuel nor generation of force.’”

Dr. Green in his paper before the medical society of Boston several years ago, asserted that “alcohol is neither food nor medicine. It cannot add one molecule to the plasm out of which our bodies are daily built up. On the contrary, it exerts upon the whole animal economy a most deleterious influence. It does not supply, but diminishes vital force. It weakens the nerves, deadens the sensibilities, lessens the power of the system to resist disease or to recover from its effects. Alcoholic stimulants *may* serve a purpose in bridging over attacks of sinking and prostration and physicians may, and often do interpret such momentary exaltation as favorable to life and health and so continue them. But the incited activity produced by such stimulants does not last many hours and cannot be extended to any great length of time, because the depressing effects which are sure to follow their use, more than counteract their power to stimulate. Alcohol cannot sustain vital force. It weakens the powers of digestion and assimilation, and cannot be long continued without disastrous effects, and these cannot be vital force except by increased power of digestion. There can be no excess in the animal economy without a corresponding loss. The momentary exaltation of the functions of either body or mind produced by alcoholic stimulants, is always followed by an increased degree of depression. Alcohol may spur a weary brain or nerve a feeble arm to undue exertion for a time, but its work is *destructive* not *constructive*, such stimulation means destruction, not added force. It is not stimulus, but rest that is required for exhaustion from excessive mental labor. It is a whip, a cruel spur, quickening speed and consuming vitality;” and he adds, “in the case of a patient rapidly sinking, I might perhaps administer whisky or brandy were nothing else at hand, but with the firm belief that the object would have been more satisfactorily attained by harmless agents. As a result of thirty years of professional experience and practical observation, I feel assured that alcoholic stimulants are not required, and I believe that many if not the majority of physicians to-day of education and experience, are satisfied that alcoholic stimulants as medicine are worse than useless, and physicians generally have only to overcome the prevailing fashion of the day, to find a more excellent way, when they will look back with wonder and sur-

prise that they as individuals and as members of an honored profession, should have been so far compromised.”

Dr. King Chambers, one of the most distinguished teachers of medicine living, says, “Alcohol leads to a diathesis of general degeneration, and as far as evidence has gone its action upon life is consistent and uniform in all its phases, and always exhibits an arrest of vitality.”

Parkes, in his work on hygiene, asks, “Are men really better and more vigorous and longer lived with than without alcohol? If distinctly hurtful in large quantities, is it not so in these smaller amounts?” He says further, “There is no question that several brain diseases, including some cases of insanity, are produced by alcohol; also degenerative changes in the stomach, liver, lungs, and probably in the kidneys.” And he adds, “To use Dickinson’s expressive phrase, ‘Alcohol is the very genius of degeneration,’ and these degenerations are not confined to the notoriously intemperate. They have been seen in women accustomed to take wine in small quantities, not excessive, and who would have been shocked at the imputation that they were taking too much, although in their case the result proved that for them it was excess. The nature of the degenerative change appears to be in all cases the same, namely, fibroid and fatty; and furthermore, considering the increase in the action of the heart and the dilatation of the vessels, it can scarcely be doubted that alcohol is one of the agencies causing disease of the circulatory organs. Its influence on the nervous system generally, and on the regulating centres of the heart and vaso-motor nerves in particular, probably arises from a direct transitory union of the alcohol with the nervous substance.”

To Fothergill, who always commands the attention and confidence of the student by his charmingly written works, I turned with peculiar interest to seek his teachings on alcohol. In his “Manual of Dietetics,” recently published, he says: “Alcohol may well engage our attention, both as a stimulant and for its food value. It is a force liberator, and has some value as a ‘food fuel.’ Alcohol requires no digestion; let that fact be kept in view. It quickly passes by osmosis into the blood. This matter becomes very important when the digestive powers are seriously enfeebled. Alcohol provides some force, and borrows some from the system, and that is where the ‘shoe pinches.’ This reminds one of the Jew who smilingly

and with great good will offers to lend money when we are in a pinch, but extorts an interest that brings ruin at the last." The doctor goes on to say: "Whenever possible or practicable alcohol should be accompanied by some soluble carbo-hydrate, which should supply the place of the borrowed force, say with some malt extract or milk. The neglect of this matter is fraught with disaster. The effect of alcohol is to produce increased action of the heart, dilatation of the carotids, and so flush the brain with blood. The flooding of the post-cerebral lobes produces a sense of well being; the patient feels better for the time, but this effect is temporary and evanescent. Such stimulation carries with it the after effect of exhaustion. The heart flags, the carotids contract below their normal calibre, and the brain becomes bloodless. If this lead to sleep, as often happens, then the alcohol may have been advantageous in every way. But the temporary time of stimulation ought to be utilized to assimilate some easily digestible food; otherwise, it may have been useless, aye, worse than useless. Alcohol is a two-edged tool, not to be used without reflection; and must be used skillfully, for gastritis might be set up if pushed recklessly, in which case the stomach rejects it quickly. Here nature steps in to limit the stimulation which is threatening the organism, when exhaustion is close at hand. This condition of exhaustion is specially liable to come on when alcohol alternately with beef tea alone is given to the patient. Beef tea is no food. Alcohol, which is a food, carrying with it a heavy borrowing power! No wonder the system is in danger of sinking from exhaustion. All this applies to acute conditions, as fevers, bronchial attacks, etc., where we wish to sustain the powers, and for that end we use alcohol. But we must so use it in combination with soluble carbo-hydrates, that we do not make it a means of sinking the ship. When administered alone, experience has told us in unmistakable accents that the end is not far off."

We are led to ask: "How can a food carry a heavy borrowing power? How can anything properly called a food be the means of sinking the ship unless administered with soluble carbo-hydrates? How can its administration, without easily digested nourishment, be 'useless—aye, worse than useless,' if it be truly a food?" One is almost tempted to believe the doctor would wish that it might not be used at all, he hedges it about with so many cautions. In his delightfully written work on "Indigestion and Bilious-

ness," he says: "There are times when generous wine may be freely drunk, not only without injury, but benefit. (It is not forgotten that careless medical instruction to drink wine freely have led to sorrowful results, nor that a patient may interpret medical instructions liberally, so as to make an excuse for alcoholic indulgence). So long as it is certain that they are doing good and agreeing with him, alcoholic drinks may be used. The physician must speak out with a distinct utterance if his ideas are well-defined and chiseled out. There is a certain unstable temperament in certain persons, perhaps a part of the neural tendency of the age, which must be taken into consideration. The magistrates are aghast at the amount of asylum accommodations they are called upon now-a-days to provide, so great is the spread of lunacy. All nervous affections are on the increase, consequently there is a growing class for which it is more or less unadvisable to order stimulants, especially alcohol. We cannot order now a glass or two of wine daily, as of yore." And further on he says: "We must be more guided by rational knowledge, by physiology, and not by fashion in our dietetics."

I turn to another distinguished advocate of stimulants, Dr. Julius Uffelmann, of Leipsic, an investigator, whose work on "Febrile Diseases" is quoted as masterly. He says: "In the treatment of acute diseases alcoholic stimulants are indispensable. It is now believed that their action of reducing temperature depends on the influence of alcoholics in retarding oxidation. It is known that they are rapidly absorbed and transformed into water and carbonic acid. We must, therefore, acknowledge them to be nutritious and antipyretic. But it cannot be questioned that large doses, even in typhoid fever, may be followed by injurious consequences. The free administration of such dilute alcoholics even as Tokay wine, has not infrequently produced intense hyperæmia and ecchymosis (as has been proved) of the gastric mucous membrane, and this, at least, should serve as a significant warning. Their effects in individual cases are sometimes *incomprehensible*, so that it is not seldom, especially among those who are not accustomed to their use, or who are of sensitive constitution, that untoward symptoms are produced, such as restlessness, extravagant dreams, palpitation of the heart and acceleration of the pulse, without increase of temperature. These effects, with the relaxation following, produce an aggravation of the affection; and even when occasioned by

moderate doses, need to be witnessed but once to serve as an admonition. The continuous use of alcohol in all cases of acute disease is followed by another evil. Alcohol is the best remedy in conditions of great prostration, and by means of it we are frequently able to obtain a life saving reaction. But if administered with frequency, it may happen that, in a moment of great need, its analeptic action may fail us. This consideration, pointed out so clearly by Liebermeister, should not be lost sight of in conjunction with the question of alcoholics in fevers. Thus, with ample reason, we arrive at the conclusion that these stimulants may be properly administered in fevers, not in the large doses now recommended, but in small doses and very freely diluted; and if we are in doubt as to the manner in which the patient is affected by spirituous liquors, the effect of a single dose should be ascertained before going further."

Dr. James Ridge, from whose papers I have before quoted, says: "Speaking from my own experience I can affirm that I see far fewer cases of extreme prostration since I abandoned the alcoholic treatment, and I cannot resist the conviction that, whatever alcohol may seem to do, its ultimate effect is to produce prostration in cases which would otherwise escape. I believe this is particularly the case where alcohol is administered *as a food*, and is relied on for that purpose, replacing materials which truly deserve the name. Alcohol, it must be remembered, has a two-fold rôle in the system. It has its chemical influence on every cell with which it comes into contact, and is in turn affected by them, *sui generis*. But, on the other hand, it has its special influence on the nervous system, and through this upon the circulatory and trophic system. On these it acts as a paralysing and inhibiting agent. Hence, if it is desired to diminish the vitality of cells, whether nuclei or wandering leucocytes, it is necessary to give such quantities as will be seriously injurious to the processes of animal life. To effect one's object we must well-nigh poison the patient. I have never found any difficulty without alcohol in enteric fever after the crisis, and believe that even in collapse from hemorrhage alcohol is contra-indicated. I altogether disbelieve that alcohol can keep a heart going which would not have gone on without it, and we are certain that reactionary fever after hemorrhage is almost entirely due to the administration of alcohol; when that is not given there is little or none."

Dr. Hammond once stated that if the

presence of alcohol taken in the form of alcoholic drinks, lessened the sum total of elimination from the human body to the extent of half a pound in twenty-four hours, it was equivalent in value to half a pound of food taken. "This idea," Dr. Davis says, "originating with men of known scientific reputation, rapidly became popular, and again furnished all classes with a plausible reason for taking alcohol as a beverage. It was claimed that by waste being retarded it was equivalent to supply, and consequently "indirect food." Those who have drawn this inference forget two of the most important physiological laws relating to animal life; first, that all the active phenomena of life depends upon and directly involve molecular change, and consequently necessitates both waste and supply; second, every cell or organized atom of living animal matter has only a limited duration of integrity or life, at the end of which it must either undergo a natural disintegration into waste matter or degenerate into an unhealthy and lower type of organization. Therefore, whatever retards the natural molecular changes, retards the phenomena of life, and by retaining cells beyond the natural limit of time directly promotes their degeneration into materials of a positively injurious character—fatty, caseous or septic materials, instead of undergoing natural dissolution and excretion as waste matter. Hence the prevention of a certain amount of waste or living structure in a given time is in no proper sense physiologically equivalent to an equal amount of new material by nutrition in the same time. On the contrary, both experiment and common observation show that if the tissue changes and waste are retarded by the presence of some agent capable of exerting such an influence, derangement of structure or function invariably follows. Alcohol's strong affinity for the albuminous constituents of the body hold the natural molecular changes in check and thereby retard these changes as seen in the diminution of temperature and the quantity of eliminations. It is not these alone that are diminished by the interference with the natural affinities of the blood, but the taking up of the oxygen from the air cells of the lungs is retarded, and the necessary change from venous to arterial blood."

A late journal records that Drs. Mosso and Maggiora, two eminent Italian physiologists, have recently been overhauling the influence of various foods and other substances upon muscular work, and by novel and ingenious methods have confirmed in a most conclusive

manner the statement that alcohol positively diminishes energy. The editor, commenting on this, says: "The sooner the popular error respecting the food value of alcohol is thoroughly exploded the better for the rising generation.

Dr. Edwards, of the London Hospital, says: "I became anxious to test the effect of alcohol upon the sick. My observations soon brought me to the conclusion that my patients recovered far better after I discontinued its use. I went on very carefully and gradually, and I came definitely to the conclusion that even in cases of delirium tremens, they did better when treated without it. For five years I had charge of the hospital. One in fifty-eight of the mothers died and one in ten of the infants. During the time I had *sole* charge, March 1st, 1868, to February 28th, 1869, with only a few shillings expended on alcoholics, out of 167 deliveries, there was only one death of the mother, (a woman in advanced consumption,) and among the live-born children one in twenty-one."

Surgeon-Major Pringle, of India, at the Sanitary Congress, said: "I have spent thirty years of my life in India. I suppose I have seen as much cholera as it falls to the lot of most people to see, and I must say, in the army the giving of stimulants was almost a fatal treatment. When nature is trying to recover herself and alcohol is administered, her whole future efforts are shut up. It is a fact than can be proved to a demonstration. Look at carbonate of ammonia! What can you possess as a finer stimulant than that? Give that to a man,—there are no subsequent depressing effects. Our duty as a Medical Congress is an important one. Of course there will be difficulties. Numbers of people object to the withholding of stimulants, because they say they are necessary; but they always withhold one great reason, which is, because they like them. We must remember we are battling with a liking. If we can tackle that, then we shall make a great stride with the profession on this important subject."

Dr. Beaumont, Lecturer on *Materia Medica*, in the Sheffield Medical School, says: "Besides inducing an inflammatory condition of the system, alcohol perverts the blood, and it is owing to this circumstance that many chronic complaints are made worse and more prolonged by the wines and other liquors ordered habitually by medical attendants. I have treated several thousands of cases of all kinds occurring in general practice, without alcoholics of any kind,

and have been gratified with the successful results. The medicines take effect more potently and answer their end better. If I must tell the truth, it is I who am the sufferer by my non-alcoholic treatment, for the patients get well much sooner, and as a natural consequence, my bills for professional attendance are very considerably less. No doubt if I were to follow the usual custom and order wines and other liquors, my patients would yield a much larger revenue in the way of fees."

Dr. Cheyne, of Dublin, Physician to the Forces, says: "The benefits which have been supposed to be derived from alcoholic agents, have invested them with attributes to which they have no claim, and we as physicians ought to make every retribution in our power for having so long upheld one of the most fatal delusions that ever took possession of the human mind."

Dr. Higginbottom, of Ipswich, says: "I have amply tried both ways. I gave alcohol for twenty years in my practice, and have practiced thirty years without it. I have not found a single patient injured by the disuse of alcohol, or a constitution requiring it; indeed, to find either, although I am in my 77th year, I would walk fifty miles to see such an unnatural phenomenon. If I ordered or allowed alcohol in any form, either as food or as a medicine to a patient, I should certainly do it with felonious intent."

Dr. Nichols, Medical Officer of the Longford Fever Hospital and Infirmary, gives interesting statistics of treatment without alcohol. In the Fever Department, 51 admitted, 43 recovered, 6 died, 2 remained. In the Infirmary, where there were many serious surgical and midwifery cases, 823 admitted, 737 recovered, 45 died, 41 remained.

Dr. Bernard O'Conner testified before the British Medical Association, "During fourteen years practice I have never used alcohol for any patient, and my experience at the Consumption Hospital, to which I have been attached for some years, has been, that consumptive patients progress very much more favorably with the absence of any alcoholic liquid than they do when alcohol is administered. I have had many opportunities of comparing the results of non-alcoholic beverages towards evenings, with those directly traced to the alcoholic solutions which are administered in the latter part of the day to consumptive patients, and the result of my observations has been that alcohol simply increases the night's perspiration, increases the night's cough, and leaves the patient

jaded about six or seven in the morning. I would call upon my professional brethren, and more particularly those who have charge of the out-patient department of hospitals and who have large family practices, to be a little more careful than they appear to be, in the administration of alcohol."

In a letter lately received from Chicago, it is stated that at the Washingtonian Home in that city, hundreds of cases of delirium tremens are treated every year without alcohol: the bromides and chloral used instead. Dr. Wilkins, of that institution, says he placed his main dependence on beef tea and plenty of sleep. At the Harrison-Street Police Station, where some of the worst cases are treated, no alcohol is used: bromides and opium the chief remedies. At other places where they object to strong opiates, they use stramonium, lupulus, fld. ext. cinchona, nux vomica, etc. In some of the late journals I notice that strychnine is used by many French practitioners; also by the Russian. The Russian *Medical Journal* reports nine cases of acute and chronic alcoholism treated by means of hypodermic injections of strychnine; and in the immediate future, the writer says, there will be abundant material at hand on observations of the effect of this remedy.

"Armed with the knowledge that science has revealed to us," says the specialist Norman Kerr, "we can with boldness thunder at the doors of our legislation, with the demand of an awakened and indignant national conscience, that proper provision be made for the treatment of the diseased inebriate, both rich and poor, and that the plague may be stayed."

Pardon me if I summon Dr. Davis to the stand for a few moments more. He says, "I speak the more positively because for thirty years I have faithfully tested the correctness of the sentiments given in relation to the therapeutic effects of alcohol, in an ample clinical experience both in hospital and private practice. I have found no case of disease,—no emergency arising from accident that I could not treat more successfully without any form of fermented or distilled liquors. The preparations of ammonia and camphor are far more speedy and efficient remedies for immediately arousing the sensibility, while in caffeine, digitaline, convallaria, etc., I have found the proper cardiac tonics for restoring permanent steadiness and force to the circulation."

It is difficult to overcome the force of habit and traditional education, and one is loath to renounce a faith that has been believed to

be well grounded; but if the testimony gathered is worthy of consideration, has alcohol other place than on the druggist's shelf, guarded as vigilantly as strychnine, arsenic, or aconite, and dispensed as cautiously and only under the prescriptions of judicious and conscientious physicians?

ABDOMINAL SECTION DONE FOR ECTOPIC GESTATION.

BY JOSEPH PRICE, M. D., OF PHILADELPHIA.

Name of patient, Mary Fultz (white).

1. Date of operation, Wednesday, March 30th, 1887.
2. Age of woman, 37 years.
3. Number of normal pregnancies, 4,—3 males, 1 female.
4. Length of survival of woman, 14 days.
5. " " " child, 4 hours.
6. Duration of gestation about 7½ months.
7. Cause of death, hemorrhage; due to walking and straining while on the commode. She was an *intractable* subject.
8. Residence, 1810 Fillmore st., Camden, N. J.

Points of Interest.—Beginning as a right tubal pregnancy, with a history of pain, shock and high temperature, indicating rupture of tube at about the fourth month, from which she recovered in a few days; subsequently her condition improved until within about two weeks prior to the operation, when she had paroxysms of pain, which required the free use of opium; this continued up to the time of the operation.

Examination.—She was small boned and greatly emaciated. Palpation showed symmetrical tumor only to be felt; vaginal—thin sack wall low down and posterior through which the extremities of the child were easily felt; cervix high up and pushed far forward; the diagnosis of "extra uterine pregnancy" had been made by her physician, Dr. Donges.

Operation.—Short incision, free discharge of bloody serum, uterus only to be seen and felt, flattened out to about six inches, forming the anterior wall of the sac. A distinct sulcus between the fundus and sac. Sac punctured in the region of the left ovary, an active female child delivered, cord severed between compression forceps, uterus contracted rapidly, forming a perfect uterine ovoid about the size of a fist, the sack also contracted rapidly. General intestinal adhesions to posterior surface of sac and uterus and laterally. The rapid contraction of the uterus and friable sac and almost genera

placental attachment rendered the stitching of sac to abdominal opening most difficult; the intestines at the upper surface of the sac were stitched to the abdominal wall.

After Treatment.—Drainage and free irrigation. The wound remained healthy and clean, large quantities of placental tissue washed away daily, patient remained free of pain, and her general condition was good until she persisted in getting out of bed that she might use the commode and not the bedpan.

Notes of post-mortem made by DR. CHAS. B. PENROSE: "The abdominal incision was united throughout. The adhesions between the sac and the abdominal walls were firm, with the exception of the upper part, where the adhesions had yielded, and a loop of small intestine about five inches in length had slipped from above into the abdominal opening. About six ounces of clotted blood were found in the peritoneal cavity. There were no signs of peritonitis. The intestines were pale and bloodless. The uterus was enlarged and flattened against the anterior abdominal wall. The remains of the placenta presented at the lower right side, and were about the size of a small fist. The placenta was adherent to the posterior surface of the uterus, to the left ovary, to the posterior surface of the right broad ligament, to the right side of the pelvis, to a portion of the ilium and of the large intestine. A corpus-luteum was found in the right ovary. The outer half of the right Fallopian tube, if present, was not removed. No examination was made of the other parts of the body."

THERMIC FEVER—A CASE.

BY E. A. WOOD, M. D., OF PITTSBURG.

A German woman, age 20, lately arrived in America, was taken ill, July 18, at 2 P. M. Saw her within a few minutes of the onset of the attack. Found her sitting on a chair limp and unconscious. Pupils contracted; pulse 120, respirations 22, thermometer in axilla 109½, temperature of air in room 98. Had her laid on the floor, and all clothing removed. Applied ice and ice-water to all parts of her body. At three o'clock the bowels moved very freely; the temperature of her body fell to 106, and pulse was 115. Continued cold externally; injected 14 grs. antipyrin into arm. At 3.30 temperature was 105. At four o'clock, for the first time, when cold water was dashed on face, she would prolong the inspiratory movement—"catch the breath," showing returning sen-

sation. Thermometer in rectum registered 104. About this time she began to have spasms of the muscles of the arms—spasms of a mixed character—alternately clonic and tonic. She also began to moan as if in distress. Applications of cold water were now left off, except when heat of surface of body indicated their use. Thermometer at five showed 103. The legs at this time began also to be affected with convulsions of like character with those of arms. Injection of one-fourth grain of morphia quickly arrested all spasms, nor did they return. The pulse was 100, pupils normal. At seven o'clock she became conscious, after having vomited profusely undigested food, in which was cucumber, taken the day previous to the onset of attack. She purged and vomited till midnight, when she slept until morning. On the morning of the 19th she was rational, complained of dizziness, with headache, soreness and tiredness. She quickly recovered.

REPORTS OF SOCIETIES.

MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT DUBLIN, AUGUST 2-5, 1887.

Special Report for the MEDICAL AND SURGICAL REPORTER, by E. S. McKee, M. D.

The Antiseptic System of Surgery.

The address on surgery was delivered by EDWARD HAMILTON, M. D., F. R. C. S. I., Professor of Surgery in the Royal College of Surgeons of Ireland, and Surgeon to St. Stevens' Hospital, Dublin. He opened his address with a glowing tribute to Robert William Smith, an illustrious Irishman, who had filled the same position twenty years before, and then went on to say:

In an address of this kind the mind instinctively turns to a retrospect of the improvement of surgery. A prominent position must be accorded in this Victorian era to the antiseptic system of surgery, still enveloped in the clouds of uncertainty and misconception, notwithstanding the work which so many eager and enthusiastic admirers have bestowed upon it. The system may be wrong in practice and founded on an erroneous theory, but it has spread throughout the civilized world, and the wonderful results that have followed it cannot be denied. Yet, we find some of its most devoted adherents abandoning parts of the system long considered as essential, and that, too, without diminution of results. Again, we find antiseptic precautions so little regarded—

may, almost set at naught—as to prompt the ovariotomist to flush the peritoneum with water containing germs and spores and thirty different kinds of beasts, and yet point to a continuous record of success little if at all inferior to the more complex method. What conclusion can the simple inquirer after truth arrive at?

It may be conceded as proved that the atmosphere that surrounds our globe is infested with myriads of minute organisms, subject to constant and restless change. These changes are largely influenced, if not changed, by their surroundings, and they again produce disturbance in their environments. Some of these can only develop in material which is dead; and are, therefore, amenable to physico-chemical laws. Others, again, are capable of living in tissue which is alive, where they increase and multiply, disarranging and vitiating the whole organism. In the first variety the effect produced is in direct proportion to the actual amount of the ferment introduced. In the second, the amount of disturbance produced is out of all proportion to the minute quantity of the poison which produces it. That these latter bodies are potent factors in supuration and infective inflammation would appear to be proved beyond a doubt. Experiments have proved that injury may be produced, either mechanical or physical, on the deep tissues of the living body, and if due cleanliness of the instruments be observed, and atmospheric air absolutely excluded, no effect whatever is produced beyond the injured spot. The hot iron, or injections of strong solutions of chloride of zinc kill the tissues, but the necrosed mass produces no ill effect on the surrounding structures.

It is certainly our duty to destroy and exclude from the body all these micro-organisms, and if the means adopted for that purpose—call them Listerism, antisepticism, surgical cleanliness, or by whatsoever name you will—turn the scale a feather weight in restoration to health, or saving the life of a single human being, the man who refuses to employ them through apathy or prejudice, incurs a responsibility nothing short of crime.

A suitable germicide is now the object of pathologists and chemists. It is interesting to watch now one, now another, lauded and proclaimed, only to be superseded by a new claimant. Carbolic acid, corrosive sublimate, iodoform, thymol, have each for a time worn the crown, only in their turn to be deposed and dismissed for new favorites.

Up to the present time attention has been almost exclusively fixed upon infective germs, sufficient regard not having been paid to the important influence of environment. We know that these atoms, no matter how virulent they may be, cannot undergo their life changes, cannot produce their infective result, unless the environment, like the cultivation fluids of the pathologist, is capable of developing and sustaining this change. Deposited on a clean glass, metal or porcelain, they die of inanition. In contact with dead organic matter or living matter, in certain conditions of altered or reduced vitality, they become a teeming source of infection, decomposition and decay. If we bring pathological surfaces to such a condition that they do not afford a suitable soil, do we not accomplish as much as when we destroy germs? Surely the perfection of antisepticism must be attained when these two conditions are fully developed and enforced.

The protective power of vaccination against small pox and the protection of the blood by the previous action of the exanthemata are examples of the influence of environment. The bacilli of splenic fever, so destructive to herbivorous animals, take little effect on carnivorous, and none at all on the pachydermata. The bacteria which will cause septicæmia in the mouse are wholly inert in the field-mouse. If we study human by comparative pathology we learn much. Look at the flood of light which has been shed by the study of the bacilli of splenic fever, chicken cholera and glanders, and by Pasteur's discovery of the cause of disease in the silk worm. We can learn much from the pathology of the vegetable kingdom. Some of the most troublesome diseases which the surgeon has to deal with are caused by the invasion of vegetable parasites. Fruit can be ripened with almost mathematical precision by interposing between it specimen fruit of the same species which is already ripe, as if the emanations from the ripe fruit exercised a ripening influence upon the fruit in its immediate vicinity. I think we see this principle of environment frequently illustrated in human pathology when disease extends to adjacent but not continuous surfaces.

This two-fold aspect of chronic inflammation was forced on my attention by trying to think out the best mode of dealing with chronic abscesses. The discharges from a recently opened abscess do not show any of these micro-organisms which are so characteristic of purulent matter in acute suppuration.

The treatment of open wounds by a solution of chloride of zinc, the method introduced by the late Campbell D. Morgan, has been the treatment of my colleagues and myself at St. Steven's Hospital for over twenty years. This has no rational foundation in histo-pathology, yet our faith in the practice cannot be shaken by the dictum of even so high an authority as Koch, who asserts that chloride of zinc is inert as a germicide and much less effective than corrosive sublimate, iodine or carbolic acid. I firmly believe that it will render a cut surface a barren cultivation field, and I think we may infer that it will produce a similar effect on the wall of an abscess.

My method of proceeding is the following: A long curved trocar and canula is pushed through the abscess, and made to transfix it some four or five inches; a piece of rubber tubing with a single hole about the centre was drawn through the canula by a thread connected with the cutting end of the trocar; the aperture in the tubing being lodged midway between the two trocar wounds, the canula was removed; one end of the tube was attached by glass tubing to the exit conduit of an irrigating can hung upon the wall above the patient's bed; the other end discharged into a reservoir at the bedside; by means of a stop cock the flow of liquid could be regulated with the greatest nicety, so that it could escape drop by drop, and render not only the contained fluid but the abscess wall, perfectly aseptic. Again, by compressing the exit portion of the tube between the thumb and finger, you can cause distension of the sac to any degree desirable, and thus produce all the advantages of the distension method proposed by Mr. Callender. And now, as to the fluid which is to be used for irrigating an abscess. In my earlier trials of course, I employed the fashionable antiseptic, carbolic acid, but my patients, after a few hours, exhibited olive-colored urine and gastric disturbance, warning me that I could not persist without reducing the strength of the solution to such a degree as to render it inert. Subsequently I employed a very weak solution of chloride of zinc, 1 pint to 200, with the best possible results. The cavity remained antiseptic; remarkable changes were developed in the wall of the abscess; thin membranous matter was discharged from time to time. After about a week the tubes through which the solutions were passed became enlarged so as to be no longer water-tight. This at first causes considerable trouble in keeping the patient dry and comfortable, but more extended experi-

ence proved that at this time continuous irrigation is not needed, the cyst wall having undergone such decided alteration in its structure that occasional syringing is quite sufficient for the perfect healing of the cavity. Such, Mr. President and gentlemen, is the treatment of chronic abscess by irrigation.

In conclusion, fellow-laborers of the British Medical Association who are engaged in surgical work, we have committed to us a goodly heritage. This Victorian age in which we live has been signalized by some most remarkable advances in all the arts and sciences. Human intellect and inventive faculties, day after day gain fresh triumphs over matter, but in none have greater strides been made than in the art and practice of surgery; more especially in those lines where it is being extended by a more careful application of anatomy and physiology. It is true that in this country experimental research, which has done so much to relieve human suffering and save human life, should be untrammelled, instead of being cribbed, cabined and confined within the four corners of an Act of Parliament, which is a reproach to the common sense of that august assembly and an outrage on the characters of the members of a profession who, whatever may be their faults and failings, have never been open to the charge of cruelty or disregard of pain.

The hysterical shrieks of a few women and the puling sentimentality of some weak-minded men, have placed and retained in the statute book the Vivisection Act. *Tu quoque* is, I believe, a bad defence; but we see them mount their horses and hunt to the death the timid hare or clever fox. I should be sorry indeed, to say a word against field sports, which have no doubt their useful purpose; I only ask for consistency, and that scientists in this country should not be placed at so great disadvantage compared with their continental brethren.

We must however, make the best use of the means at our disposal, and carry forward the standard of investigation into new and unexplored fields. One by one the dark caverns of the body are being illumined by the light of scientific surgery, even the ivory walls which guard and protect the dome of thought are pierced by its rays, and the brain itself mapped out with geographical precision, as in a chart; so that we can by careful reading of the symptoms place our finger on the very spot oppressed by injury or disease, and then by a bold and decisive operation lay it bare, and remove the cause of its morbid condition or disturbed func-

tion. There is ample room and verge enough for work—many untrodden fields of discovery, so that we can make the future of Queen Victoria's reign as glorious in the annals of scientific discovery, and as full of help to the sick and wounded sufferer, as it has been in the past.

At the same meeting, Prof. T. Grainger Stewart, of Edinburgh, discussed

The Incidence of Albuminuria Among the Sick.

Following up the inquiry as to the incidence of albumin in urine presumably healthy, reported to the Royal Society of Edinburgh, the author has made a series of observations on various groups of patients to which he had access, as to its incidence among the sick. These patients consisted of 150 consecutive private patients, 150 consecutive cases from the wards of the Royal Infirmary, 100 consecutive out patients, 50 cases from the wards of the hospital for sick children, 40 cases from a ward devoted mainly to the treatment of cases suffering from alcoholism, 50 patients from the fever hospital and 25 cases of women from the maternity hospital.

In each case the urine was examined with nitric acid, picric acid, and Fehling's solution.

The author then presented a series of tables.

Table I. Showed that among the private patients 36, or 24 per cent. showed albumin; among the indoor patients of the infirmary 10 per cent., and among the sick children 7 or 14 per cent., among the fever cases 38 or 66 per cent., among the maternity cases 10 or 72 per cent.

Table II. Dealt with the causes of the incidence of the albuminuria in the 150 private cases. Thirteen out of the 36 were due to Bright's disease, 1 febrile, 2 vascular, 3 alimentary, 2 glycosuria, 8 functional, 6 accidental, and one probably accidental.

Table III. Dealt of the probable causes in the 150 indoor infirmary cases: 74 cases of albuminuria were met with in the wards, 26 were from Bright's disease, 5 febrile cases, 10 vascular, alimentary 6, nervous 5, glycosuria 53, cases accidental 5.

Table IV. Dealt with the probable cause in 100 outdoor infirmary cases. Of 19 showing albuminuria, 8 were from Bright's disease, 3 as probable Bright's disease, 5 vascular, 1 alimentary, 1 glycosuria, 1 probably accidental.

Table V. Dealt with the cause in the 50 children. Bright's disease occurred in 1 case out of the 7, probable Bright's disease 3, febrile 3, nervous 1.

Table VI. Showed the results obtained as to the occurrence of albuminuria amongst 50 fever cases in the Edinburgh Fever Hospital. Of the 50, 18 or 36 per cent. showed albumin with nitric acid, and 38 or 72 per cent. with picric acid. Taking the 38 cases of scarlet fever separately, we find that 13 or 34.2 per cent. showed albumin with nitric acid, and 23 or 30.53 per cent with picric acid.

Table VII. Showed the results in 40 cases of alcoholism, either acute or chronic, treated in the Royal Infirmary. The specimens were obtained on the morning after their admission. One would naturally expect a large proportion of albuminurics among such patients and no doubt the per cent. is high. Still we must remember that the class of patients of whom this group is composed is most closely related to that of the soldiers, that is, the conditions of life such as heavy bodily labor, etc., which in soldiers, conduce to make albuminuria frequent, and also operative here. Still, the percentage of albuminurics is distinctly higher than it is amongst the soldiers, and, indeed, more closely corresponds to the statistics obtained among the indoor infirmary patients. While, therefore the albuminuria is probably mainly to be ascribed not to alcohol, but to the conditions of life, the alcohol must be credited with the increase over what we would expect in healthy individuals of the same class. This may be partly a direct effect of the alcohol, but doubtless the indirect influence as regards inferior diet, bad hygienic conditions which intemperance involves, are also factors in the case.

The next question is, how we are to explain the albuminuria in these various conditions. I shall not attempt to do this until I have gone over the results of experiments made by different observers, with the view of clearing up the question. Certain inferences seem to be warranted from the facts I have stated:

1. That in health, so in disease, albuminuria is more common than is generally supposed.
2. That it is more common among patients of adult age than among children.
3. That cases of Bright's disease do not account for one-half the cases of albuminuria met with in practice.
4. That they account for more than any other individual cause.
5. That next to them rank the changes in the renal circulation due to cardiac and other maladies, and accidental cases due to the admixture of blood, pus, etc., with the urine.
6. That so far as this series of observation shows, cyclical, diatetic and simple persistent albuminurias are rare.
7. That

while in Bright's disease, especially the waxy and cirrhotic forms, the quantity of albumen is at first so slight as to be only shown by picric acid, it yet is more abundant than in albuminuria due to other causes. 8. That in the digestive and nervous cases, and those due to high temperature, the quantity is often so small as only to be discovered by picric acid.

We now turn to note the results of our observations as to the occurrence of peptones in the series of cases examined. Table VIII shows incidence of peptonuria in the series of cases examined. It thus appears that only 4 out of 150 patients showed this condition. These cases were: 1st. A case of cirrhotic Bright's disease, with gout and dyspepsia. 2d. A case of cirrhotic Bright's disease with heart disease. 3d. A case of rupture of the kidney; and, 4th. A case of acute rheumatism. The urines were all albuminous. Of 150 indoor patients at the Infirmary, 16 gave the reaction. These were a cases of dyspepsia, a case of malignant disease of the liver, stomach, lungs, etc.; a case of heart disease; two of phthisis (one of them syphilitic); a case of pleurisy; nine cases of Bright's disease and a case of acute rheumatism. Except in the case of dyspepsia, all the urines contained albumen as well.

Dr. G. Apostoli, Professor of Gynecology and Electro-Therapeutics at Paris, then discussed

The Treatment of Fibroid Tumours of the Uterus by Electricity.

The author who is well known in gynecological literature, said that the great danger to life resulting from the surgical interference in these cases together with the inefficacy of drugs had caused him to look about for something more satisfactory. This he had found in the method which he had termed galvano-chemical cauterization. This might be vaginal, intra-uterine or parenchymatous, but was always monopolar.

In the hands of his predecessors electricity had been used in a vague and indefinite manner, those using it not knowing how much they were using. His method was energetic, tolerable, better localized and thoroughly under control. He insisted upon absolute and regular antiseptic vaginal irrigations before and after each operation. The punctures should not be more than one or two centimeters in depth and should be made by a small steel trocar or needle, the most prominent point of the tumor should be punctured, and this should, if possible, be done in the posterior cul-de-sac.

The anatomical and clinical results to be expected are:

a. As regards the material changes we may affirm that every fibroid tumor submitted to this treatment, sometimes after so short a time as one month, but certainly when the treatment is fully carried out, will undergo a manifest reduction of size, a reduction appreciable by the touch, and demonstrable by internal measurement. The further diminution of the tumor which continues for some months, varying in amount from one-eighth to one half of the original volume, is generally associated with a coincident and equal accumulation of subcutaneous adipose tissue on the abdominal walls. The retrogression of the tumor is not only apparent during the time of active treatment, but goes on continuously after it has been stopped, and is the persistent proof of the enduring influence of the electrical operation.

The liberation of the tumor from its local attachments takes place simultaneously with its decrease of bulk. The tumor, which at the commencement of the treatment was immovable, can progressively be made more and more to change its position, as the absorption of the enveloping tissues deposited round it advances.

Another phenomenon is observed in connection with the retrogression of the tumor. It not only contracts on itself but shows a tendency to separate from the uterus, to become more distinctly sub-peritoneal, to detach its mass as it were, from its setting in the uterine wall, and to remodel itself into a pedunculated form.

b. Clinically the results are not less striking. Perhaps they are even more so, as they are not only matter of proof by the examination of the surgeon, but the patient herself is the living exhibition of them. We may generalize the extent and importance of these results by saying that ninety-five times out of one hundred, they comprise the suppression of all the miseries constituting the fibroidal symptomatology. These cases may be categorically enumerated thus:—Hemorrhages; the troubles of menstruation, dysmenorrhea, amenorrhea, nervous disturbances; the direct pains in the growth itself, and those arising from mechanical pressure; and the harassing series of reflex actions.

In a word, the assertion may be safely advanced that, though our therapeutic resources only carry us so far as the sensible reduction of fibroid tumors, and not to their total absorption, we may with regard to the symptoms, certainly anticipate their complete removal, and the establishment of a state of

health equivalent to a true resurrection. I am justified in saying that the greater number of women who have persisted in the necessary treatment, not only were cured, but remained so.

I use the expression "greater number," because there is no such thing as infallibility, especially in medicine. I acknowledge having been sometimes unsuccessful, and so instructive are my failures that I shall recount them at length in a work now preparing. It will be seen they were cases in which there was no possibility of satisfactory treatment, owing to an apparently absolute intolerance of high intensities of current. I see now that I was wrong in retreating before this supposed intolerance. Among them were three cases of fibroma with ascites, and I now regret that with the aid of an anæsthetic I did not persist in going to the limit of my power. I have also met with the same intolerance in some hysterical subjects, in cases of very irritable uterus, and in others of periuterine and intestinal phlegmasia. Now with my present experience, I should not hesitate to operate to the fullest extent under chloroform. There yet remains the obscure question as to the class of cystic fibromas, and tumors with a tendency to malignant degeneration, where there is often a fearful and irrepressible hydrorrhœa accompanying. I have recorded three such instances, and in them intra-uterine galvano-cauterization generally proves useless. Something more is demanded and we must seek in galvano-punctures a means of denutritive action more powerful and more efficacious.

Finally, I may lay down the following proposition: No operator should admit the failure of intra-uterine galvano-cauterization before having had recourse to the galvano-punctures, which he must enforce either with or without anæsthetics.

We will now turn aside from all theoretical considerations, and look at the facts. I may rely upon them with confidence as my great support. I desire, however, in the first instance to prove the comparative safety of intra-uterine medication when my method is adopted.

Both in my clinic and in private consultations, as far as regards gynecological practice, the application of electricity therapeutically assumes two forms. In the one it is exclusively faradic, and in the other galvanic. For the present I pass over faradism to occupy myself solely with the patients who have been subject to the treatment by continuous currents.

In the five years from July, 1882, to July, 1887, I have made either privately or at the clinic as many as 5201 applications of continuous galvanic currents, for most of the maladies included in gynecological nosology, and I may enumerate them in the following order:

Fibroids of the uterus, polypi, entire or partial hypertrophy of the uterus, subinvolutions, acute and chronic metritis, ulcerations of the neck of the uterus, periuterine inflammations (perimetritis, parametritis, cellulitis, phlegmons), ovarialgia, ovaritis and periovaritis, salpingitis, ovarian and tubercular cysts at an early stage, atresia, hematocele.

These 5201 operations were thus classified:

1. At my clinic, 2837.
 - a. 1524 galvano-cauterizations, chemical, positive, intra-uterine.
 - b. 749 galvano-cauterizations, chemical, intra-uterine, negative.
 - c. 368 galvano-punctures, chemical, negative, vaginal.
 - d. 200 cauterizations, galvano-chemical of neck of uterus.
2. In my private practice, 2864.
 - a. 1245 galvano-cauterizations, chemical, positive, intra-uterine.
 - b. 1027 galvano-cauterizations, chemical, negative, intra-uterine.
 - c. 72 galvano punctures, chemical, negative, vaginal.
 - d. 30 galvano-cauterizations, chemical, of neck of uterus.

These 5201 operations which range over a space of five years, were made upon 403 patients, who went through the treatment more or less systematically. I must not omit to mention that I intentionally say nothing about the number, for in one of the above, who were made the subjects of faradism, as I intend publishing a separate memoir on that subject.

Now, in referring to the history of these 403 patients, 276 at the clinic, 127 private, I have only to deplore the loss of two. Of these two deaths I take upon myself the entire responsibility. My method was not at fault. I alone was to blame as may be seen by the full and detailed report.

In one case I admit candidly there was a fatal error in my diagnosis. I did not recognize the presence of a suppurating ovarian cyst, which ended in death from peritonitis. In the second case death was due to a puncture made too deeply. The consequence was intra-peritoneal gangrene, for which the abdomen was not opened.

In addition I have to confess to having either excited or aggravated, in the course of the five years, ten periuterine phlegmonous inflammations. These must be attributed to blunders in carrying out the treatment, as will be shown when the account is published at length.

But errors of practice happened during the earlier days of my work, and were either negligence of antiseptic measures, which were either altogether omitted, or done imperfectly; or, the too violent or too intense use of the negative pole, in cases of subacute periuterine inflammations.

The fact is, that the negative pole, having a strong power of producing congestion, is a dangerous weapon, which at the beginning of any treatment must be used with great prudence and reserve, if one would avoid overshooting the mark for which it is intended.

To lay before you the facts of these accidents will serve the double purpose of warning you of what may befall, and preventing you from making similar errors. My caution is that whenever the negative pole is put to use, and there is any trace of periuterine inflammation present, you must not only redouble your antiseptic heedfulness, but your operative proceedings must be carried on with deliberate carefulness. You must feel your way, testing the susceptibility of your patient by two or three preliminary operations, in which you can give doses so feeble that they only serve to enlighten you and habituate the patient so as to lead on safely to the use of higher intensities.

But when I tell you that this operative gynecology, as I have to practice it, is carried on in such exceptional circumstances that no one else has ventured to encounter them, and upon a class of women who are obliged to walk home shortly after they get up from the couch, who seldom take the necessary rest in bed, and whom poverty forces in some fashion to get through with the ordinary duties of life, you will ask of me with curiosity, the explanation of this illusive mystery. All that I can say is, it appears to me that the intra-uterine current at the high proportions I trust to, seems to have in itself some special antiseptic and atrophic property.

I must close these remarks on the failures which I have no wish to conceal, but expose to you in all their nakedness, though they so stand as the evidence of only the usual difficulties which accompany the laborious and misty development of any new method. I do not speak of other dangers which lie in the way, such as the possibility of concealed

pregnancy, and accidental abortion, and also the risk of opening up a vesico-vaginal fistula. I have already enlarged on this matter elsewhere, and in my next work on gynecological electrical therapeutics, I shall devote a chapter to the needful precautions.

I am anxious to-day as the completion of my paper to bring forward a simple statistical statement of what has been my treatment of uterine fibroid.

From July, 1882, to July, 1887, I have had under my care 278 patients with fibromas or hypertrophy of the uterus in some manifest degree, upon whom I have used 4246 applications of currents of electricity. The patients and operations may be thus classified:

I.—Clinique. 188 patients, and 2347 operations.

1433 Galvano-cauterizations, positive, intra-uterine.

598 Galvano-cauterizations, negative, intra-uterine.

321 Galvano-punctures, negative, vaginal.

II.—Private. 92 patients, 1898 operations.

1085 Galvano-cauterizations, positive, intra-uterine.

746 Galvano-cauterizations, negative, intra-uterine.

68 Galvano-punctures, negative, vaginal.

As I said before I do not wish to convey the impression that all these patients have been cured. It is not so for the reason that some of them have not persevered to the end, especially in the clinique, the attendance having been discontinued upon the first feeling of amendment. But I can affirm that where there has been no negligence, 95 times out of 100 permanent benefit has been acknowledged. I may also predict that if adopted in its integrity and worked out as it should be, the mortality henceforward will be nothing. The following is a report which gives occasion for melancholy comparison. Among the patients who had not the will to let me finish the work begun, and whose impatience lead them voluntarily to seek the removal of their tumors by excision, seven put themselves into the hands of our most eminent surgeons, and not one of the seven recovered from the operation. Comment on this would be superfluous.

One word in parting. Men and their labors can, in general, only find their proper level and value through the esteem of their associates, and the way in which their work is publicly accepted. If my method ever meets with the confidence of the profession, (to speak only of England) it will be mainly

due to your illustrious countryman Sir Spencer Wells, who was one of the first to extend to me the benefit of his experience and authority; and to his learned friend Dr. Woodman Webb, whose name will ever be coupled with its introduction and diffusion. It would be injustice, were I not also to refer to the honor, such distinguished gynecologists, as the Keiths, father and son, Playfair, Savage, Elder and others have done me by their visits, and the encouragement given me by their approbation. I cordially thank all who are present, and assure you that the best recompense of the work of my life will be to find many of you becoming my followers.

cologists, as the Keiths, father and son, Playfair, Savage, Elder and others have done me by their visits, and the encouragement given me by their approbation. I cordially thank all who are present, and assure you that the best recompense of the work of my life will be to find many of you becoming my followers.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Treatment of Gonorrhœa by Injections of Iodoform Oil.

Dr. Thiéry (*Le Progrès Medical*, March 3d, 1887,) says, that amongst diseases of the genito-urinary tract few have called forth methods of treatment at once so numerous and so inefficient as gonorrhœa, and this multiplicity itself shows the difficulties to be encountered by the physician when he undertakes the care of this malady, so common and so productive of grave consequence. The patient demands prompt relief, and the aim of the physician is not only to accomplish this but to secure a radical cure.

Now, gonorrhœa left to itself tends to spontaneous resolution, and although a bacterial disease, it has a well-marked cyclic evolution and is often seen to get well without any treatment. This, however, is the exception, largely because of the imprudence of the patient, whose excesses cause the gonorrhœa to pass into a chronic state, and it is this chronic gonorrhœa which is so frequent and so rebellious.

Three methods of treatment may be employed. The expectant which sometimes succeeds; the emollient followed by balsams; and the abortive. We employ at the Midi Hospital the second method in preference to the others, from having observed its good results, and we do not hesitate to say that the treatment, properly carried out, almost always succeeds when the patient can manage, and is desirous of a complete cure. The following is the plan followed:

In the first period. 1. Patients are absolutely forbidden to drink beer, coffee, liquors or white wine, or to visit women, and are to be cautioned about touching the eyes with the hands.

2. Three times per week they are to take a full bath of an hour's duration.

3. Water colored with red wine may be taken with meals, but no other drink is allowed. Each day, between meals, a quart of water is to be drunk, in which forty-five grains of bicarbonate of soda has been dissolved.

4. A suspensory bandage is to be worn.

Second Period. 1. The same rules are to be observed as laid down under Section 1 of preceding rules.

2. The baths and bicarbonate are to be omitted and no liquid is to be taken between meals.

3. Six large pills of the following confection are to be taken each day:

R Pulv. cubebæ.
Pulv. copaviæ.....āā 5 j
Magnesiæ.....q.s. ut. confect

If all these conditions are filled, and if the directions are carried out in all their details, and all the deprivations which they entail are put up with, success may be guaranteed. Wine and women have however such strong attractions for the hospital population (and they are so urgent in their demand for a speedy cure) that abortive treatment was introduced. This, however, is painful, and in inexperienced hands dangerous, and in most cases should be rejected.

The author, after using bichloride, nitrate of silver and other injections, has met with greater success in the employment of iodoform suspended in oil, a means of treatment which he characterizes as "active, rapid and absolutely innocuous." After trying saturated solutions of iodoform in ether, which were found too painful, a mixture of ether, iodoform and oil of sweet almonds was used, but both were given up in favor of a simple suspension of iodoform in the oil. About two drachms are injected in the usual way, after urinating, and retained for some time in the canal. The claim is made that iodoform adds to the antiseptic and microbian action an analgesic property which is of great value.

The odor of the drug is found to be sufficiently hidden by the addition of vanilline, coumarine, or spirits of eucalyptus.

Six cases are reported which were treated in the manner described; five were completely cured in from five to twenty-eight days, and the sixth was nearly well on the sixth day of treatment, when he left the hospital, making an average of thirteen days. From eight to twenty-nine injections were given.—*Jour. of Cut. and Genito-Urinary Diseases*.

Scarlatinal Uræmia in Children.

The uræmic symptoms which are noticed in diseases of the kidneys do not always arise in the same way and cannot all be explained upon the same ground. An especial significance attaches to those cases of scarlatinal nephritis in which the uræmic complex of symptoms appears without diminution of the quantity of urine, and sometimes even with an increased quantity. In five cases in point which the author reports, it is unfortunate that the anatomical condition of the kidneys is not in all cases clearly recognizable. In all these cases, however, the quantity of urine reached on the day before death at least the normal, frequently exceeded this amount very considerably, while the specific gravity showed no deviation from the normal. For the explanation of uræmia in these cases, the chemical theory is, according to the author, altogether useless, and cedema of the brain is invoked as the explanation. Upon the ground of theoretical observations, he thinks that the cause of the latter is a hydræmic condition of the blood, and disease of the blood vessel walls, as a result of the scarlatinal poisoning.—JACOBOWITSCH. *Centrallblatt f. d. med. Wissensch.*, July 9, 1887.

Note upon a variety of Transient Erythema arising in a person taking Choral and Alcohol Internally.

The fleeting eruption arising after the use of chloral hydrate, which has been many times described, happens, according to the author's experience, most frequently in young children; and of these the most frequently affected are those who have used at the same time some alcoholic beverage, such as wine, beer, etc. In cases where the face was affected in a very marked manner, the author saw at times the conjunctival as well as the mucous membrane of the mouth and throat, either as a whole or in spots, strongly reddened, glistening and dry. The breath

of the patient, always, but only at the time of the eruption, gave a peculiar odor, reminding one of chloroform. Daily doses under forty-five grains were but rarely followed by an exanthem. Moreover, the author saw the same thing occur in two children who had taken alcohol but no chloral. BARBILLION in *Centrallblatt f. d. med. Wissensch.*, July 2, 1887.

On Diseases of Wild Animals.

Dr. H. C. Chapman says that nine-tenths of these suffer from heart diseases. Elephants suffer most from rheumatism, monkeys die ordinarily from lung or heart affections, the feline family of dysentery and heart disease, the canine of all possible diseases.—*Deutsche Medizinal-Zeitung*, July 14, 1887.

Ménière's Disease.

In the interest of the nosology of Ménière's disease (which the author thinks is better called Ménière's vertigo) it seems to be demanded that the severe cases marked by deafness that arises suddenly and quickly should be separated from the lighter forms, as both possibly depend upon a different anatomico-pathological basis. Many cases of the severe form could be attributed to hemorrhage into the labyrinth; many of the lighter forms to vaso-motor neurosis. But Brunner believes that hemorrhage has been allowed too wide a scope in the explanation of Ménière's vertigo, and is inclined to think that a large number of cases depend upon pathological conditions of pressure in the labyrinth; and that the interference with or obstruction of collateral paths for the peri and endolymph plays an important rôle in this. The following seem to the author indications of a neurotic (vaso-motor) cause of the disease: 1. A vertiginous aura preceding attacks. 2. Slight and only gradual appearance of disturbance of function. 3. A certain regularity and frequency of attacks. 4. The action of quinine in cutting short or weakening attacks (eventually also galvanization of the cervical sympathetic). For a case in point, contributed by the author, see the original article. The favorable influence of large doses of quinine is explained by the author as due to the production of a high degree of ischæmia of the labyrinth, just as has been proved to occur in the retina.—BRUNNER. *Centrallblatt f. d. med. Wissensch.*, July 9, 1887.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Compendium and Pocket Record, 7.00	

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,000 copies.

SPECIAL NOTICE TO SUBSCRIBERS.

Subscribers to the MEDICAL AND SURGICAL REPORTER, who have remitted payments to the former editor, and who do not find upon the wrapper of their journal a correct statement of the time up to which they have paid, are requested to notify the present publishers as soon as convenient.

ARTIFICIAL DIABETES.

Prof. Langendorff, in some recent investigations into the artificial diabetes produced in frogs by strychnine and curare, comes to the conclusion that under the influence of the former poison the degree and persistency of the diabetes are dependent upon the glycogenic capacity of the liver, and the season of the year; while the diabetes induced by the latter poison (curare), is independent of the liver, occurring after removal of that organ from the body, but only lasting one or two days.

As to the influence of seasons, the author found the maximum quantity of sugar in the autumn, during which time the liver of the

frog is stored with glycogen to be used gradually during the winter; at this season the diabetes lasted generally four or five days, occasionally a week or over. The farther the winter advanced, the shorter was the duration of diabetes, in spring sugar continued in the urine on the average one or two days. The author was able to imitate this influence of season, by placing upon ice some freshly captured summer frogs that had been recently fed and keeping them there several days, thereupon, strychnine diabetes appeared, though under other circumstances it was absent at this season of the year. *Vice versa*, when the author had kept winter frogs which are rich in glycogen for two to four weeks in warmed water, poisoning by strychnine produced no sugar in the urine, or only a trace of it, while the liver was diminished in size and entirely free from glycogen. Moreover, under the influence of strychnine diabetes, the change in the weight of the liver was very striking. While the average weight of the liver of non-diabetic autumn frogs (which contain a large store of glycogen) was two and a half grammes, this average was reduced to one and seven-tenth grammes after induction of glycosuria, the liver being at the same time entirely free from glycogen. To confute the possible supposition that glycosuria in strychnine poisoning is due to muscular spasm, the author states that in frogs paralyzed by curare, but non-diabetic, he was able to induce diabetes by strychnine. Therefore muscular action is not the cause of diabetes. Prof. Langendorff believes that "the nervous system stands in a relation to the glycogenic function and to secretion of sugar that is similar to that existing between secretory nerves of other glands and their respective processes, and that strychnine would then be the source of direct or reflex stimulation of the secretory nerves of the liver."

Seegen, of Vienna, in his researches upon the quantity of sugar in the blood of diabetics, claims to have found a decided increase in the severe forms of the disease. It is of great interest that in two of his cases

having a mild form of the disease, the ingestion of food rich in starch increased decidedly the amount of sugar in the urine, without increasing the quantity of sugar in the blood. It will be remembered that Bernard maintained that an increase of the normal quantity of sugar in the blood was a necessary condition of glycosuria. If these results of Seegen are confirmed, glycosuria can not be considered as an increased glycæmia. A further item of interest in this connection is contained in the paper of Theil, of Königsberg, on experimental diabetes in birds. He explains the difficulty of producing artificial diabetes in birds upon the ground of the extraordinary powers of oxidation which birds possess.

In concluding a review of these highly valuable observations, it can only be said that at present they are not explicable by our present knowledge of the disease. They indicate, however, that what is at present known as diabetes mellitus can be divided into several diseases; and that one of these will probably be referred in a causal way to disease of the central nervous system and another to disease of the liver.

ON THE EMPLOYMENT OF KEFIR IN THE DISEASES OF CHILDREN.

We learn from the Austrian correspondent of the *Semaine Médicale* that Professor Monti, of Vienna, employs kefir with excellent results in the diseases of children. He uses for this purpose pure cow's milk.

For infants under three months, the milk employed for the preparation of kefir should be diluted with equal parts of water. For infants between three and seven months, a mixture may be made of two parts of milk and one part of water; and for children between seven and fifteen months, the preparation should be three parts of milk and one part of water.

The kefir is prepared in the following way: A quantity of kefir grains is soaked five or six hours in warm water, then put into a glass of milk, where they are left till

they rise to the surface of the milk and become white, which takes two or three hours. A tablespoonful of the grains thus prepared is added to a pint of milk, which is then covered with a cloth; the mixture is shaken or stirred every two hours for eight hours, and kept at a temperature of from 63° to 65° F. The milk is then poured into a bottle which is hermetically sealed, and exposed to a temperature of 63 to 65° F.; the bottle is shaken every two or three hours. The kefir thus prepared differs according to the length of time the fermentation has been going on. Kefir No. 1 is the product of twenty-four hours fermentation. It is a thick drink, slightly acid, containing but little alcohol and carbonic acid. Kefir No. 2 is the product of two days fermentation. It is sourer, thicker, and foams in the glass. After a fermentation of three days (kefir No. 3) the richness of kefir in alcohol and carbonic acid is still greater.

There is another very simple process of preparing kefir, namely, by mixing equal parts of milk and kefir, prepared in the way indicated above, and shaking the mixture several times a day. In adding to milk a small quantity of kefir a beverage is obtained at the end of two or three days, equivalent to kefir No. 1 or 2.

Levy has recently prepared a Koumiss almost identical with kefir by adding curdled milk (bonny-clabber) to eight or ten parts of boiled milk, and repeatedly shaking the mixture, then exposing it to a temperature of 54° F. According to Monti's analysis, the quantity of alcohol and carbonic acid contained in this beverage is less than that in kefir No. 1, and he regards it as quite different from kefir. The physiological action of kefir is due to the presence of lactic acid, carbonic acid, alcohol and peptones.

Infants soon learn to like kefir, and take it readily, seldom vomit it, the healthy action of the digestive canal and the kidneys is promoted by it, and the weight of the body augmented.

Kefir grains come from Caucasia, and the preparation of Koumiss from kefir is familiar to the populace of Eastern Europe.

NOTES AND COMMENTS.

MODERN TREATMENT OF COMMON DISEASES—DYSPEPSIA.

General Consideration.—Before giving some of the newest formulæ for the medicinal treatment that is suitable in different groups of cases, there are some statements applicable to the disease as a whole. 1. Medicines of themselves rarely if ever cure the disease, they are adjuvants and palliatives. 2. For a cure we must always aim to discover and remove the cause. 3. The most diverse influences may manifest themselves as some one of the many possible forms of dyspepsia, and we must be prepared to run the whole gamut from phthisis to masturbation, and from some obscure cerebral disease to simple constipation. It is quite possible that even when the cause is discovered, the stomachic condition will still remain the only manifestation of the disease that we are able to treat. This fact, while it enhances the importance of skill in the treatment of dyspepsia, at the same time vastly modifies prognosis. 4. Though the possible causes are many, the most frequent are bolting of food improperly masticated; indigestible food, or food that is unsuitable to particular persons; insufficient clothing, particularly of the feet. Whatever lowers the general bodily health, may, in a person predisposed, operate as a factor in the production of dyspepsia. Under this head belongs a sedentary life or close confinement in a vitiated air, such as many clerks and saleswomen are obliged to endure.

It will be seen that improved hygiene and a diet adapted to the digestive powers and requirements of the individual cover the ground. But to the average patient and to not a few physicians, "hygiene, regimen and diet," the cardinal principles upon which alone dependence can be placed for a cure of dyspepsia, are not presentive words pregnant with meaning; but mere catch-words, to be rattled off glibly because they sound well, and have a certain professional ring. We have called them principles, and properly used each one should serve as the basis for categorical question and answer from each patient, regarding whatever may cause or perpetuate the disease. Nor is it sufficient to inquire and obtain an answer. Whenever possible, make a personal examination.

Attempts to divide dyspepsia into different forms have been unsatisfactory. For therapeutic purposes, it is better to simply recol-

lect that the disease is a unit, but that every case must be subjected to a comprehensive and yet critical and minute examination. After this has been done, take the symptoms that seem to the patient most urgent and direct remedies to those.

Pain in Dyspepsia.—Sometimes this is the only symptom, as in gastralgia; sometimes it is the result of digestion that has been retarded until fermentation has produced acids. It may then take the form of heartburn; or if the offending matters have been carried into the intestines, give rise to colic; distension and rumbling in the bowels, or pain may be due to an excessive acidity of the gastric juice itself. Other less distinct forms of pain, amounting to weight, heaviness and various degrees of discomfort are rather common.

The value of some of the older methods of treatment has been well established. These are briefly: For the acute attack, copious draughts of hot water just short of scalding, combined with the local application to the epigastrium of a rubber bag containing hot water, or of a mustard plaster, or still better in some cases, a blister. Morphine hypodermatically is often demanded. During the intervals between the attacks, or in less severe cases, Fowler's solution before meals (gtt i-ij), small doses of nitrate of silver and belladonna in pill form, or dilute hydrocyanic acid.

For more recent remedies, we turn to the pages of Ewald's last edition, and obtain the following: Valerianate of Bismuth. This remedy Ewald recommends as one whose value has been many times verified. It should be given in pill or powder.

R Bismuthi valerian. gr viiss

 Sodii bicarb. gr. ccxx
 Elæosacch. calami. gr. xlv
 Sacch. lactis. gr. cccclxxv.

M. SIG.—To be taken on the point of a knife in
 cardialgia from excessive acidity of the gastric juice.

Ewald also recommends inhalations of
 nitrite of amyl.

In addition to the formulæ just given,
 alkalis after meals or acids before meals (as
 recommended by Ringer), are useful in pain
 from acidity of the stomach. When this is
 due to fermentation, salicylate of soda, about
 one hour after meals, is valuable.

Nux vomica with a dilute acid often acts
 very happily when given before meals in
 cases where heart-burn develops after meals.
 Anstie also recommends strychnine hypo-
 dermatically in gastralgia and gastrodynia.
 "There is," says he, "no such remedy as
 this." Besides the remedies already men-
 tioned, chloral, charcoal and manganese de-
 serve mention. When there is pain with
 acidity and flatulence, charcoal is often
 advantageously combined with an equal
 quantity of bismuth, say ten grains each, as
 suggested by Ringer.

Scarlet Fever and its Treatment.

Clement Dukes, M.D., London, writes to
 the *British Medical Journal*, July 9th, 1887:
 The Journal of June 11th, 1887, contained
 a valuable article by Drs. Jamieson and
 Edington on "A Method of Prophylaxis,
 and an Investigation into the Nature of the
 Contagium of Scarlet Fever." They have
 proved that the specific cause of scarlet fever
 is a bacillus, which they have cultivated,
 and with which they have inoculated animals
 and produced scarlet fever. They have also
 shown that this bacillus occurs in the blood
 during the first three days of the fever;
 that, later on, it is absent from the blood;
 and that it is found most extensively in the
 desquamating skin after the third week.
 They have, further, indicated a method by
 which this bacillus can be destroyed in the
 skin, and thus the spread of the infection of
 scarlet fever can be minimized, and the un-
 protected, even while residing in the same
 house, be safe from falling into its trammels.

But a still more important matter is the
 treatment and arrest of scarlet fever in each
 individual; for the first cry of a parent
 whose child has scarlet fever, is, "What can
 you do to save my child; and how can you
 spare him from becoming maimed for life
 by its sequelæ?" his second question being,
 "How can you prevent its spreading to my
 other children?" This second question
 Drs. Jamieson and Edington have answered.
 It is with the hope that I may induce them
 to investigate the first question that I am
 writing this paper; for it has already been
 brought within a measurable distance of
 being answered by Dr. Illingsworth, of
 Accrington, who, in a letter in the *Journal*
 for May 1st, 1886, stated that the biniodide
 of mercury ($Hg I_2$) is a specific for scarlet
 fever. Recognizing the importance of his
 letter in the use of mercury as a germicide,
 I resolved to administer the drug at the
 earliest opportunity. I have now given the
 $Hg I_2$ in several cases of scarlet fever—with
 this result, that it not only arrests the fever,
 but it prevents the desquamation of the skin,
 or arrests it to such an extent that only a
 slight scurfiness of the skin of the hands and
 feet arises. If such be found to be invari-
 ably the case, will the bacilli of scarlet fever
 be found in the skin at all; and, if not, will
 not the infectious period of scarlet fever be
 thereby reduced to a few days only, and will
 not the sequelæ of scarlet fever be absolutely
 prevented?

The $Hg I_2$ can be administered in the
 form of a pill or as a mixture of the liq. hyd.
 perchloridi c. pot. iodid. The only draw-

back to its use which I have at present found is that if it be given before the diagnosis is absolutely certain, the physician will be apt to think, when he finds no desquamation taking place at the usual time, that the case was not one of scarlet fever. The drug prevents the desquamation of the epithelium of the tongue, as well as of the skin, and the throat rapidly heals under its use.

I was busy collecting the facts when Drs. Jamieson and Edington's valuable paper appeared, and I should have waited until I had collected a sufficient number of instances before writing this paper had it not been for the desire that others, especially the above-named authors, would assist in establishing, or refuting, this treatment, for the experience of one individual is limited.

The benefit to be obtained from the use of Hg I₂ is far-reaching if it be reliable in all cases, for it not only prevents the desquamation of the skin, and thereby probably prevents the major part of the infectious nature of scarlet fever, but it will probably also be found that it obviates the necessity of keeping patients in bed for three weeks, which is the only safe rule hitherto, and isolated for five or six weeks, and will prevent the occurrence of the much-dreaded sequelæ.

The gist of the whole matter seems to be this: 1, that if the bacilli of scarlet fever are only discovered in the blood for about three days; 2, that if the bacilli, after this date, chiefly occupy the desquamating cuticle; 3, that is this desquamation can be prevented altogether by a medicine which destroys bacilli; 4, then, in all probability, the infection of scarlet fever will only last a few days, and we are within a measurable distance of limiting the spread of scarlet fever, and of removing its fangs by preventing the sequelæ.

The Abortive Treatment of Furuncles.

Dr. Louis Heitzman, of New York, writes as follows: After it was shown, some years ago, that micro-organisms are the actual causes of furuncles, it is rather surprising that parasiticides have not long ago been used in the local treatment of boils. It is well known that among the numerous parasiticides, salicylic acid often does excellent service in diseases of the skin, but in furuncles it has, to my knowledge, never been used. I therefore tried to abort furuncles with salicylic acid, plaster or salve, and the result was really surprising, for it acted beautifully. The first case in which it was used was that of a young man, who, for

three weeks previously had suffered from a large number of boils of different sizes at the back of the neck. In spite of numerous incisions, new nodules appeared as soon as others were cured. The man suffered such pains that he was unable to sleep, and he could not turn his head in the slightest degree without most severe pains. When I saw him first, he had about one dozen larger and smaller elevated, indurated, inflammatory nodules on the left side of the back of the neck. I prescribed locally an eight per cent. salicylic-acid plaster:

R	Acid. salicyl.,	5 ij
	Empl. saponat.,	5 ij
	Empl. diachyl.,	3 j

When I again saw him, three days later, the pains had disappeared, he could move his head in every direction, and only a few superficial nodules remained; in three days more he was cured. I had opportunity to test the action of salicylic acid in furuncles several times, and almost every time with the best success. If applied early enough, it never took longer than six or eight days to cure furuncles of even a large size and of long duration, and the relief to the patient was manifested in a very short time. It is immaterial whether the salicylic acid is used as a salve or in the form of a plaster, the effect is always the same, and a five to ten per cent. salicylic-acid salve is of the same service. I use the officinal Unguentum aquæ rosæ as the basis for salves, not only because it has an agreeable smell, but because it is harmless; and this cannot always be said of vaseline, which is sometimes not free from sulphuric acid. A pleasant way to use the salicylic acid is in the form of the ten per cent. mull, which was first introduced by Unna; it is used in the same way as the plaster, and causes a superficial formation of blisters, or a sloughing of the skin.

If, as I hope, the salicylic acid will prove as efficacious in other hands as it has in mine, we have a means to cure the furuncles every time as soon as they are formed, and, if applied early enough, necrosis will never set in. I have noticed that, if applied too late, no core will be formed, but merely an accumulation of pus, which can be treated as a common abscess. If necrosis of the tissue is once present, salicylic acid also will have no more effect, and the best thing then is to open the boil with the knife, and hasten the cure by application of the salicylic acid salve. This treatment of furuncles is very simple, and is, I think, to be preferred to an injection. Whether this mode of

treatment is also efficient in carbuncles and felons I do not know, for I have had no opportunity to use it in these. In all probability a favorable result will be seen even here, since salicylic acid first macerates the epidermis and then softens it, whereby it can quickly penetrate into the skin and kill the staphylococcus.

In conclusion, a few words about the general treatment of furunculosis and about the so-called furunculoid diathesis. It cannot be denied that a badly nourished person or one weakened by disease offers, on account of the great irritability of the skin, a more favorable soil to the staphylococcus than a healthy individual, and an improvement of the general health, as far as it is in our power, is certainly indicated. The local treatment, however, is by all means more important in furunculosis than the general, since it gives immediate relief to the patient. I know of cases where a furunculosis, which had lasted for weeks and months, was cured by the local application of a one per cent. salicylic-acid salve. Special care must be taken that the salicylic acid is equally divided throughout the salve, and all the patient has to do is to apply it every morning and evening in a thin layer.—*The Med. Record*, August 6, 1887.

The Pathology of Lumbago.

At a recent meeting of the Society of Biology, Féré, in discussing the subject of lumbago (*tour des reins*) remarked that this affection consists in a pain more or less severe, seated in the lumbar region, and manifesting itself suddenly after a violent effort. This pain disappears in a space of time, which may vary from one to four weeks. Valleix considers it as a "rheumatic pain," supervening in individuals predisposed, and seated in the muscles. It is generally admitted that "sprain in the back" (*tour des reins*) consists of a rupture of the muscular fibres, determining an effusion of blood and local pain. Fricard and Nielly regard it as a "neuralgia of the lumbar and sacral plexus," and they reject the theory of muscular rupture. The existence of a neuralgic element in certain cases of "sprained back," or lumbago, seemed to Féré to be put beyond doubt by a case which had come under his observation. Besides the lumbar pain, there existed certain *points douloureux* along the track of divers branches of the lumbar and sacral plexus. These painful points indicated "neuralgia of the superior, gluteal and obturator nerves, and external popliteal branch of the sciatic." These three nerves can be affected

simultaneously in only one point, namely, at the emergence of the fourth pair of lumbar nerves, which sends to them filaments. There was, then, reason to believe that Féré's patient had neuralgia of the roots of the fourth lumbar nerves. Féré thought it altogether improbable that this neuralgia could have been due to "compression or traction" of the nerve branches during the exaggerated contractions of the psoas muscle, and external muscles of the vertebral column. Nor did the hypothesis of compression of nerves by blood effused from ruptured muscles, seem to him probable. The only tenable hypothesis, then, was that of "neuritis or neuralgia."

No more common or more troublesome affection vexes the general practitioner than what is called *lame back*, *sprained back*, or lumbago, and what is the exact pathological condition cannot yet be defined. According to one of the most recent medical lexicographers (Robin), "lumbago is a very painful state of contractions (sic) suddenly manifesting themselves throughout a part or the whole extent of the sacro-lumbar muscles, twenty-four to forty-eight hours after a chill. This pain, so keen during each contraction and extension of the muscles, is continued for eight or ten days, gradually ceasing, with or without treatment. There is no neuralgic condition of the skin. It is a manifestation in the sacro-lumbar mass of a state of the muscular tissue, which is sometimes also produced under similar circumstances, in the trapezius, sterno-mastoid, deltoid, etc. Frictions, massage, sinapisms, galvanism, hypodermic injections of morphia or ether, the use of tighter belts or bandages attenuate the pain and diminish its duration."

Senator (Ziemssen's Cyclopædia) classes lumbago among the myalgias. It is sometimes due to a strain and muscular rupture; sometimes to cold and damp. True cases of lumbago, which are confined to the lumbar mass of muscles, are, he says, not likely to be confounded with neuralgic pains which are apt to be of a wandering, fugitive character. The treatment is essentially the same, whatever may be the cause. Of late, remarkable results have been reported from methyl chloride spray.

—"How much calomel did you sell to that man for a quarter?" asked the druggist of his clerk. "One drachm," he replied. "Mercy, you'll compel me to make an assignment at that rate! Don't you know that stuff costs us forty cents a pound?"

Medicine: Before, With or After Meals?

Dr. J. Edward Green, of Macon, Ga., says, in the *Atlanta Med. and Surg. Journal*, June, 1887, that as all medicines are poisons to a certain extent, and that as in most instances they set up abnormal action in the human system, it is better to administer them upon a full stomach. This applies especially to two classes of remedies, those which are constructive in their action, and those which act as irritants. Remedies of the latter class, coming in immediate and direct contact with the branches of the pneumogastric nerve, set up violent convulsive action of the whole alimentary canal in order to expel the offending material, thus frequently eliminating the substance before it has had its effect on the system. The effects of opium and alcohol, taken on a full, and on an empty stomach, are illustrations of the points under discussion. As regards tonics, Dr. Green says that the best time for their administration is after eating. For, given on an empty stomach, they excite an excessive flow of the gastric juice, which, having nothing upon which to act, is either re-absorbed, or does positive injury by its corrosive influence on the mucous membrane. Iron and arsenic are illustrations of this point. Cod-liver oil is best given on a full stomach for two reasons—1st, When ingested while the stomach is empty, it irritates the pneumogastric nerve, which promptly causes its expulsion. 2d. The gastric juice exerts little or no solvent power on pure oily matters, and consequently the effect is *nil*. In order to effect a certain organ or locality, it is necessary that the remedy should permeate the whole system. This cannot be accomplished when such irritation is set up as to cause the expulsion of the medicine before it is absorbed. Iodide of potassium in syphilis is an illustration of this. To sum up, it may be stated that all medicines which are irritant in their action, all constructive agents, all alterative, all remedies which are to be thoroughly carried into the system, and all alcoholic stimulants, had better be given with, or just after, meals.

Treatment of Scrofulous Glands.

H. C. Rogers, M. D., in the *New York Med. Journal*, June 25, 1887, discusses the difficulties in the treatment of strumous glands, and alludes to the large number of strumous children with slowly suppurating cervical and other lymphatic glands, which, after months or years of suffering, end in elevated or depressed cicatrices and un-

sightly scars. Under the most careful and judicious treatment the surgeon is liable to disgust his patient and bring discredit on himself.

During the past two years he has pursued one of two lines of treatment: 1. Teak's method of dissecting out the enlarged and inflamed glands and scraping old sinuses. He has resorted to this method in three cases, with results which were all that could be desired. The only objection to it is that it is quite an operation and cannot be adopted without an anæsthetic. To this the parents and friends of the children frequently object, remarking that they would rather take a longer time than to have any operation performed on their little ones.

2. He has treated nine cases by the method of Professor Verneuil, which consists in first evacuating the abscess by aspiration with a large-sized trocar, handling the parts as little as possible. Then as soon as the liquid becomes slightly blood-stained he injects the cavity with a five per cent. solution of iodoform in ether. The largest quantity used is about 3 fluid ounces, generally an ounce to an ounce and a half suffice. The amount of iodoform remaining in the abscess cavity to be absorbed rarely exceeds one drachm.

Dr. Roger's experience has been that generally one injection will be sufficient. In only three cases has he found it necessary to repeat the injection into the same swelling. In four cases he injected glands where he could not find pus, but where the centre of the swelling was soft and in a condition to break down. In such cases his plan is to inject from ten to twenty minims of a two-per-cent. to three per-cent. solution. In all cases the swelling is gradually reduced, so that in from four weeks to three months it has entirely disappeared. In all his cases he has employed internal treatment, as all the patients were more or less anæmic. Up to some six months ago he had been using a tonic containing arsenic, iron, and iodide of potassium; but, on account of the difficulty apothecaries have in making up a pleasant mixture that children would take, he has had some trouble in keeping up the treatment with regularity.

—A little "fresh-air child," who had never seen a cow before, was watching the milking process with eyes full of astonishment. After looking on in astonishment for some time, she drew near, and, placing her hand on the cow's distended side, exclaimed: "Why, she's chock full of it, ain't she?"

Experimental and Clinical Studies upon Tuberculosis.

These studies, published under the direction of Prof. Verneuil, of Paris, acknowledge their indebtedness to a summons issued by Verneuil, for a collection of prize contributions which should be related to assisting and advancing the investigation of tuberculosis. Eighteen large and small treatises, relating to the pathology and therapeutics of tuberculosis, were thus obtained, and some of them will be here discussed:

1. *The Phenomena of Karyokinesis in Tuberculosis*, by Cornil.

Cornil's report is based upon his investigations concerning the histogenesis of tubercle. With reference particularly to the karyokinetic phenomena, he comes to the result that under the influence of tubercle bacilli, both the connective tissue cells, as well as the endothelium of the vessels and the epithelium, begin to divide themselves and to multiply. In this way the well known so-called epithelioid cells arise. Then the bacilli pierce even into the vessels, remain fixed in the capillaries, and hence lead to a wandering out of white blood corpuscles, which collect around the tuberculous new formation.

2. *The Weakening of Tuberculous virus*, by Gosselin.

Gosselin has sought, in different ways to obtain a weakening of tuberculous virus. Next, he tried to determine whether inoculation of tuberculosis in animals, who are difficult to infect by artificial means, (carnivorous animals, crows, dogs), called forth a change in the virulence of the poison. These propositions, however, proved incorrect. Through inoculation with the tuberculous material of sick dogs, rabbits could be made as easily and firmly tuberculous as in any other way. Also in the virulence of the bacilli of severe tuberculous diseases and in those of milder, local, "benign" affections (as of bones and articulations) no difference was shown. Through injections of blood of tuberculous animals the disease could be transferred frequently. If the first injection remained without result, the animals did not on that account have immunity from infection. Animals could be easily infected, who sometime before infection had received daily injections of corrosive sublimate, iodide of mercury or iodoform. So, also, after infection had taken place, injection of mercurial preparations had no effect. On the contrary, iodoform seemed to strongly hinder the tubercle bacilli in their development. Rab-

bits that had been injected, remained healthy for a month by daily injections of iodoform. Immediately upon stopping the iodoform, tuberculosis set in.

3. *Upon the means of making the organism rebellious to Tuberculosis*. By Raymond and Arthaud.

These authors believe that the tubercle bacilli, just according to the state of their development, show a certain polymorphism, and that this corresponds, also, to their virulence. Particularly, there are certain zoogloea forms of the bacilli which possess decidedly insignificant virulence as compared with the ordinary rods and spores. Experiments to artificially alter the morphology of bacilli, seem to be hopeless. The same authors also experimented to obtain an immunity for animals through the introduction of medicines. Iodoform was without effect, while tannin seemed in this connection to have a certain influence.

4. *Upon experimental tuberculosis*. By Daremberg.

By inoculation of tuberculous masses by means of trephining, an artificial tuberculous meningitis was produced. The fresh spinal marrow of a tuberculous animal, even though the same animal had no meningitis, acted virulently. Experiments to produce immunity to tuberculosis, analogous to the well-known methods of Pasteur, had no result.

5. *Upon some of the histories of hereditary tuberculosis with reference to experimental facts*. By Landouzy and Martin.

These men have observed that the five children of a tuberculous father all died of tuberculosis, while the mother was and continued to be perfectly healthy. In this instance, an introduction of the disease through the semen seemed very probable. In order to obtain confirmation of this view, they inoculated sixteen guinea pigs with the semen of eight tuberculous rabbits. Six of the sixteen inoculated animals became tuberculous.

6. *Upon tuberculosis arising congenitally and suddenly*. By Prof. Lannelongue.

This is a clinical communication upon observations concerning tuberculosis of the bones and articulations, etc., in children a few weeks or months old—a theoretical essay upon the different possibilities of infection.

7. *Upon tuberculosis of the liver*. By Brissaud and Toupet.

This work treats of tuberculosis from a purely anatomico-pathological point of view. From their detailed account we gather that the attempt to recognize tubercle bacilli in the liver is frequently unsuccessful, because,

as they believe, the bile exerts an influence upon the coloration of the bacilli. In opposition to most other authors, they believe that the first tubercle is developed in the capsule of Glisson, and in the connective tissues associated with it, without having its point of origin in the portal vessels. Finally, they hold that there is also a specific, tuberculous cirrhosis of the liver, of a chronic inflammatory nature, without a proper tuberculous new formation.

8. *Upon pre-operative treatment.* By Verneuil.

To obviate evil results in operating upon persons in whom there is a localized tuberculosis, the author recommends the previous injection of iodoform, which has a deleterious influence upon the bacilli; and to administer daily thereafter to the patient from 5 to 15 cgr. of iodoform. When protected in this manner, evil results in his clinic very rarely occur.—*Allgemeine Med. Centrall-Zeitung*, July 2, 1887.

Aromatics and Bacteria.

The ancients, it is well known, used aromatics in much the same way as we now use powerful antiseptics. The late Mr. Rimmel devoted a considerable portion of his life to demonstrating that bodies of an aromatic character, such as essential oils, are antiseptics; and the views which he expressed are quite in accordance with those now accepted. M. Chamberland has recently reported upon the action of essential oils on the bacteria of charbon. Only 14 out of the 115 oils which he used had no effect on the bacillus, and oil of cloves was included in the number. Oil of cinnamon completely destroyed the germs in four days, whilst bacteridian germs placed in fresh yeast-water have been cultivated after having been for four days in contact with other oils. Cassia oil does not stop the development of filamentous bacteria, but oil of vespetro seems to kill it completely in eighteen hours. Placed in contact with carbuncle bacillus, or its germs, in solution, seven oils killed that bacterium. These oils were found to have about the same antiseptic power as sulphate of copper. Amongst these oils are cassia, cinnamon, and thyme oil, which, however, are only of full power when fresh and unoxidized. Experiments were also made with thymol; and summing up, M. Chamberland states that the most energetic antiseptics were corrosive sublimate and thymol. Sulphate and acetate of copper and bichromate of potash, although very ac-

tive, allowed vegetations to grow; next to them in power were cassia oil, persulphate of iron, carbolic acid, alum, and sulphate of quinine. Boric acid, hyposulphite of soda, salicylate of soda, arseniate of potash, bisulphite of soda, chloride of alumina, and chloride of lime, are comparatively weak antiseptics.—*Chemist and Druggist*.

Palpation of Lymphatic Glands.

At the instance of Penzoldt, Dietrich investigated the number and size of the lymph glands that were normally palpable in four hundred and thirty-nine healthy soldiers and pupils. In this examination were included the glands of the occipital, cervical (cervical and supra-clavicular), axillary, cubital and inguinal regions. He found that nearly all healthy persons have some region or other in which the lymph glands are normally palpable, and that the most common region is the inguinal, in which they are found in 92.9 per cent.; next they are most frequently found in the cubital region (82.6 per cent.); then in the neck (79.4 per cent.); and least frequently in the occipital region (2.2 per cent.). As to the average number of palpable glands, it is greatest where the most lymph glands lie, that is to say, in the inguinal region; then follow in decreasing ratio the neck, axillary, cubital and occipital regions. Children have a higher percentage of palpable lymph glands than adults. The average number of glands decreases in general with advancing age; this is most strikingly seen in the neck. The average size in different regions of the body is about the same at all ages, namely, that of a lentil or bean. In fifty persons with florid secondary syphilis, the percentage of the whole number of palpable lymph glands as compared with the healthy, showed an increase in the average number and in the average volume of the glands, and this increase was especially marked in the cervical and inguinal glands. On the other hand, a general glandular swelling was not constantly found in syphilitics, though the cubital glands in number and in size were more marked than in the healthy. In sixty-nine adult patients with diphtheria an average increase in the swelling of the cervical glands was established, though this was wanting in children (perhaps accidentally: the submaxillary glands were not considered). General glandular swelling in diphtheria at least, is by no means regularly present.—*Centrallblatt f. d. med. Wissensch.*, July 9, 1887.

How to Make Sponges Antiseptic.

Upon this subject, Bernbeck writes as follows: "Select sponges of moderate porosity; if they are too fine it is difficult to free them from sand and lime. Next, dry them, and free them from the coarser sand by repeated beating with canes. After this, place them upon a coarse hair-sieve, and wash them until the last water runs off absolutely clear and free of sediment. When this has been accomplished, soak the sponges for about two hours in a solution of potassium permanganate 1-1000, and then add crude hydrochloric acid until the violet color entirely disappears. This manipulation presents three advantages: while the sponges are disinfected, they are also bleached through the formation of free chlorine out of potassium permanganate and hydrochloric acid; and finally the residue of the lime, which often clings with great tenacity to the sponge, is dissolved by the excess of hydrochloric acid, and thus easily removed.

Subsequently, the sponges are repeatedly washed with water until the latter no longer reddens litmus paper.—*Deutsche Medicinal-Zeitung*, July 14, 1887.

Adulteration of Morphine.

J. Geo. Spenzer, of Cleveland, describes the results of analysis of a sample of morphine, as follows: This morphine, of foreign make, was offered for sale at a very low figure, but was represented to be quite pure. Its solution was, however, repeatedly complained of as producing excessive irritation when used by the hypodermic method. It was observed that the solution, although at first apparently clear, would throw down a precipitate. On examination this proved to be sulphate of calcium. Other samples of morphine sulphate were examined, some of which also showed the presence of this same impurity, but this could hardly account for the irritating effects produced by the solution. The other specimens were all strictly neutral in their reaction; this, however, was distinctly acid, and it was apparently the excess of acid which rendered it irritating.—*Western Druggist*, July, 1887.

Transplantation by Exchange.

Mr. C. B. Keetley, surgeon to the West London Hospital, reports an operation which he calls "transplantation by exchange." The operation was performed on a child with a very large mole on the face, and consisted of the reflection of a flap from the child's arm upon the face, and the implantation of the

mole on the arm, to prevent excessive cicatricial contraction interfering with motion.

The flap from the face was left attached by its inferior; that on the arm by its superior border. The two were then rotated into position and secured there by sutures; the arm having been brought close to the face for that purpose. A plaster-of-Paris bandage was then applied, so as to keep the arm close to the face and at rest. Both flaps lived, having been severed from their bases on the twelfth day. Nine months after the operation the result was announced as being quite satisfactory.

Dioscorine in Hepatic Colic.

A judge of one of our highest courts was reduced to the verge of the grave with frequent attacks of that excruciating malady, *hepatic colic*. He had the best medical advice that Georgia could give; he vainly sought distant watering-places and other physicians; he was a wreck; gave up his business and lost hope. He was advised to take fluid ext. wild yam—dioscorine—by some one, and never after did he have an attack. I do not mean that one dose cured him, but that from the beginning of its use dated the end of his trouble. He is now one of the finest specimens of the physical man that you meet in our city of healthfulness. He imparted this information to me five years ago. My success with the remedy in hepatic colic has been simply all that I expected or desired. It heightens the pain-relieving power of opium during the attacks and prevents their return when the remedy is continued. I will not worry you with details, but affirm that I have cured cases where parties had suffered for years with oft-repeated attacks.—DR. J. S. TODD, *Atlanta Medical and Surgical Journal*.

A Peculiar Case of Iodism.

This interesting case is reported from the Clinic of Von Ziemssen: A factory hand, twenty-four years old, suffering from chronic lead poisoning, was taking iodide of potash, and instead of the coryza and salivation customary in iodism, a diminution of the saliva, accompanied by enormous swelling of the parotid glands asserted itself. The voice was harsh and barking, the radial pulse 130 and scarcely perceptible, urine scanty and containing many white and red blood corpuscles, and later, also, free hæmoglobin.—RIEDER, *Centralblatt f. d. Med. Wissenschaft.*

CORRESPONDENCE.

Ruptured Perineum.

After some experience in the suturing and non-suturing methods of treatment of ruptured perineums, I read a short paper on the subject before the Indiana State Medical Society a few years ago, in which I favored the latter method, keeping the patient on her right and left side alternately, her genitalia clean and her knees together.

I referred to a number of cases thus successfully treated, in one of which the laceration was so extensive that it was impossible for the patient to retain her fæces. I asserted that in all cases where sutures succeed in effecting a speedy union of the severed parts, nature would likewise succeed if proper care and cleanliness were exercised. My paper was surprisingly well received by the society, but at the following meeting a year later; was vigorously attacked by a leading gynecologist of Indianapolis, who considered it criminal to allow a ruptured perineum to remain unsutured, and that in every case, if properly done, immediate union will result.

The time which has elapsed since my paper was read has served but to strengthen me in the position then taken. Subsequent cases have not only strongly fortified it, but one of them has entirely negatived the proposition of my antagonist, that "in every case if properly sutured, immediate union will result." The case to which I refer was a German woman in the City Hospital, Fort Wayne, unmarried, aged 35 years, whose first stage of labor began Wednesday, February 23, 1887. On the following Sunday, the 27, after an hour's manipulation with my hands alternately employed, I succeeded in making room sufficient in which to apply the forceps, when I delivered her of a child, still born, weighing ten pounds, rupturing her perineum throughout more than half its entire extent, which I *immediately* closed "properly" with three deep sutures, before she recovered from the effects of the chloroform. Not a particle of union occurred and the sutures were removed in four days when septicæmia threatened. In this case neither method would have been successful because her general system was at fault. She requires constitutional treatment before the parts are revived, after which, if her condition is right, either method will prove successful if "properly" attended to. Dr. Hamilton, of New York, in a paper contributed to the *Journal of the American Medical Association* three years after my own was read as

above mentioned, supports me fully in the position I take upon this important practical question.

DR. H. V. SWERINGEN.

Fort Wayne, Indiana.

Medical Epitaphs.

EDS. MED. AND SURG. REPORTER:

Sirs: I brought home with me from England, the other day, these epitaphs, which may interest you. I never saw them published.

J. M. KEATING.

In Bunhillfield's Cemetery, London:

"Here lyes Dame Mary Page, Relict of Sir Gregory Page, Baronet.

She departed this life March 11, 1728, in the 56th year of her age.

In 67 months she was tapped 66 times. Had taken away from her 240 gallons of water without ever repining at her case or fearing the operation."

From a tombstone in the cemetery at Winchester, England:

"In memory of — who died of a violent fever contracted by drinking small beer when hot. May, 1764. Aged 26.

Here sleeps in peace a Hampshire Grenadier,
Who caught his death by drinking cold small beer.
Soldiers, be wise from his untimely fall,
And when ye're hot drink strong or na't all.
An honest soldier never is forgot,
Whether he die by gunshot or by pot.

[Epitaphs *per se* are, of course, painfully out of place in a journal devoted to the science of cure; but those above given are too edifying in matters of causation and symptomatology to be omitted.—EDITORS OF THE REPORTER.]

Country Practice in Texas.

MEDICATED BOUGIES.

Some time ago I was treating a case of enlarged prostate and wished to introduce cocaine directly to the irritable membranous portion of the urethra, and keep it there. I tried the porte-caustique and bougies, made of coca butter, etc. At last I thought of the ordinary tallow candle; selected a tube of proper size and length, pulled a wick through it made of several threads of silk twist. I then melted in a test tube, oil of theobroma, medicated to suit the case, pouring it into the tube, so as to have the medicated portion just where I wanted it. The tube is then held a few moments in ice water until the oil hardens. Now rub gently through the fingers and the oil next the tube softens.

When the candle is drawn out, again insert it in ice water and it immediately hardens, and you have a medicated bougie, manufactured in less time than I can describe it, at a nominal cost. I always prepare them at the bed-side, and have used them in all cases of gonorrhœa, stricture, diseased prostate; in fact, wherever I wish to keep the diseased surfaces apart, or introduce remedial agents into cavities, sinuses, etc.

GRASS LINE FOR LIGATURES.

In two cases of ovariectomy I recently performed, I was at a loss what to use to ligate the pedicle. On other occasions I had used silk, but the only samples I could now procure were the iron-dyed, and so brittle, I could not safely rely on them. I chanced to examine some fine grass lines, *i. e.*, fish lines, very fine, yet exceedingly strong, which I used in ligating the pedicle. In the last case I removed both ovaries, using the grass line ligature. My patient made an excellent recovery, the highest temperature being $99\frac{3}{4}^{\circ}$, and was quite well in twelve days. I don't know what the grass fish line is made from, but it is certainly the best material for ligatures I ever saw. I enclose herewith a specimen, and would like very much to know how it is made. ARTHUR E. SPOHN.

Corpus Christi, Texas.

[The tackle dealers state that this line is known as West India Islands grass line.—EDITORS OF THE REPORTER.]

Gonorrhœa.

EDS. MED. AND SURG. REPORTER:

Sirs:—Having lately a rather unique case, or rather having uniquely treated a case of gonorrhœa, I beg to offer the same for publication:

D. D. called on me with a well-developed case of this disease in its first stage. Judging him to be of a scrofulous nature I gave him internally grs. v iodide potash, and gtts. v Fowler's solution daily. For local use as an injection, aqua $\frac{3}{4}$ iv., acid carbohc gtts xx, to be used twice daily after carefully cleansing the urethra with clear water. He returned in three or four days practically cured.

JAMES BATES, M. D.

Warren, O., Aug. 8, 1887.

Large Doses of Morphia.

EDS. MED. AND SURG. REPORTER:

Sirs:—Your note of the 3d inst. at hand. There was no slip of the pen nor mistake in saying that during 12 pays she took one grain

of morph. sulph. every half hour, making 576 grains in that time. [See REPORTER, Aug. 13, 1887, p. 227.] She then took one grain every hour for a few days, and as the inflammation declined the interval between doses was increased until she only took one capsule per day, but the amount was kept 1 gr.

I talked with her husband to-day, and he says at no time was she narcotized, and generally was calling for her medicine by the time the half hour was up. The pain was excessive. She was convalescent by the last of January, and her husband says to-day she is able to do as much work as any woman in the city. Yours truly, A. ADY.
Muscatine, Iowa, Aug. 6, 1887.

Purpura.

EDITORS MED. AND SURG. REPORTER:

Sirs:—In the REPORTER for August 6th, Dr. E. T. Blackwell, of Cedarville, N. J., referring to my report of a case in REPORTER of July 23d, speaks as if such cases were of common occurrence; but as there stated, "I have never seen nor read of a case similar to my own."

Dr. Arthur Van Harlingen, of Philadelphia, says: "Purpura consists in the development of variously sized and shaped non-elevated or raised, smooth, reddish, hemorrhagic patches characterized by not disappearing under pressure."—(*Hobbes' Surgery*, vol. 3, p. 462.)

Drs. Thomas Hillier and Tilbury Fox, of London, Eng., in an article on Purpura say, that "*the discolored spots are not themselves raised*," (italics mine,) but under the heading of *purpura urticans* they say, "it is characterized by rounded and reddish elevations of the cuticle resembling wheals, but which are not accompanied like the wheals of urticaria by any sensation of itching or tingling," (italics mine)—(See *Reynolds' System of Medicine*, vol 1, p. 460). In the same article, on page 463, they refer to a case marked by slight elevation reported by MM. Barthez and Rilliet; those authors, however, considered it to be a case of *erythema* complicated with extravasation into the cutis. See also case reported by Ollivier, same page. In Prof. Austin Flint's description, the whole consideration of the case is summed up in less than two pages of his excellent work on "Practice;" while I do not find anything in the article which would lead one to expect elevation of the spots above the surrounding surface. It was in this particular symptom that I thought the case unusual.

Now, as to the term "cerebral pneumonia." In my MS., I wrote: "I considered the case to be what an editorial in the *Therapeutic Gazette* for January, 1887, terms 'cerebral pneumonia.' " Dr. Blackwell will thus see that I have the authority of so advanced a writer as Dr. H. C. Wood or of R. M. Smith, the editors of that journal, and had my article come out as written, it would have saved me the blame of burdening our medical nomenclature with another name. The first R in my article of July 23d should read as follows:

R Tr. ferri chlor. 3 ij instead of 3 j
 Liq. potas. arsen. 3 ss " 3 js
 Aquæ q. s. ad. 3 j

Hoping to hear from Dr. B. with reports of many cases through the columns of the REPORTER, I remain, fraternally yours,

A. A. NEFE, M. D.

Whetstone, Iowa.

Salol.

EDITORS MED. & SURG. REPORTER:

Sirs.—Will you kindly furnish through the REPORTER some information concerning *Salol*? If *antipyretic* as well as antiseptic what are the doses, and can it be given in *solution*? How would it do in solution with alcohol in a case of continued fever?

W. N. SHERMAN, M. D.

Kingman, Arizona.

[*Salol* is unlike most of the other derivatives of coal tar in that it is made by the combination of carbolic and salicylic acid. For this reason it is sometimes called salicylate of phenol. It was first recommended as a medicinal agent by Sahli, of Berne, and his paper has been followed by several others of an exhaustive character, notably by that of Georgi.

Naturally it has been found of benefit in rheumatism in the dose of 15 or 20 grains in capsules, or in pills of from 3–5 grains. It possesses according to Georgi marked antiseptic power; and two French observers, MM. Perrin and Potain, have lately published reports of surgical cases where rapid healing took place under its use as an antiseptic. This in a case of finger amputation, with a *salol* dressing, healing took place by first intention.

It is better in his opinion than iodoform for several reasons, although it is used in the same manner. It is also recommended by some of the German writers in the form of

a wash in leucorrhœa with fetid discharge and also in erysipelatous inflammations. Some of the physicians who have used it think it a good antipyretic in dose of 5–15 grains.

This last power, however, has not as yet been proved to exist. Its advantages over salicylic acid and the other salicylates is, that it is not so apt to disorder the stomach since it is absorbed in the intestine, at least this is Georgi's theory. As a dressing it lacks the strong and disagreeable odor of carbolic acid or iodoform. The reports are so far so favorable as to warrant it a further trial. Recently Dr. A. H. Goelet has highly recommended its use in doses of one grain every two hours, coupled with ice water enemata, in diarrhœas of children. He gives it dry upon the tongue. His results justify a further trial.—EDITORS OF THE REPORTER.]

NEWS AND MISCELLANY.

The Value of a Life.

The courts as a rule, fix the value of a person killed by a railroad at \$5,000, but vital statisticians place the value of an adult person to the State at \$750, and the annual productive power at \$95. One-half of all deaths occur during the productive age. The total annual deaths in the United States during this age is 200,000, therefore creating a loss of \$150,000,000. There are, also, 1,500,000 persons sick all the time in the United States, causing a loss of \$142,500,000.

A large per cent. of deaths is caused by preventable diseases. In view of this fact, can any reasonable person object to any legislation which will tend to secure a reduction of so costly a sacrifice? State and local boards of health are created to this end, but their work must be supplemented by the co-operation of the people.

The relative market value of the different parts of the human body has been calculated by a German mathematician with a view to fix a basis for the award of damages in case of disablement. The loss of both eyes, arms, legs, hands or feet, is put at 100, that of the right hand at 60, of a foot at 50, of the left hand at 40, the right thumb at 33½, an eye at 22, the left thumb or right forefinger at 14, the left forefinger at 8, and any other finger of the left hand at 4 per cent.

Dr. Hiram Corson.

Dr. Mary Willits gives the following pleasant description of a visit to Dr. Hiram Corson:

A few evenings ago, in company with some medical friends, I called upon a prominent member of the profession. After a long drive over rough country roads, past many farm-houses nestled among the trees, we turned into a drive which led us to a large, comfortable stone house situated in the midst of a level lawn across which several large trees threw their shadows. As the carriage stopped, we were met by a man rather above the medium height, spare in person, with snow-white beard and hair, who beamed a kindly welcome through his spectacles when he greeted us and presented us to his wife, whose welcome was not less warm as she led us indoors.

An ideal host we found him, engaging each one in conversation separately for a few minutes, making that one feel, for the time being, that no other guest was present, and then causing the conversation to become general, leading it into channels interesting to all of us.

I speak of Dr. Hiram Corson, of Plymouth Meeting, Montgomery County, Pa., who, although he will be eighty-three years old in October, is in vigorous mental and physical condition, bidding fair to render service to humanity for some years to come; as he is still in active practice, but rarely goes out at night, as his wife informed one of our party.

A little distance from the house is "the office," a frame building with one room, on one side of which are shelves, almost from floor to ceiling, well filled with books and bottles of drugs, the latter being a necessary part of a country physician's armamentarium. A table in front of one of the windows was covered with manuscript, and the doctor informed us that he was writing a paper on the use of "Cold Applications in Inflammation." Every one knows what an advocate of this treatment he is. Scarcely were we seated in the parlor before he asked one of our number if he had ever used "cold." This led to a general discussion on the subject, and Dr. Corson spoke of its being so superior to poultices in pneumonia. Upon being asked *how* he applied it, his reply was: "I take a bladder, or rubber ice-bag, fill it about half full of water and then put in pieces of ice; to put in pieces of ice alone makes an uneven surface, which is not readily applied to the chest."

He has used cold applications in many diseases—in scarlatina to reduce the temper-

ature and allay the throat symptoms. He has observed in this disease that if the cerebral symptoms were well marked the throat symptoms were not so prominent. He thinks the reason for this is that, when the cerebrum is much affected, the whole nervous system is affected and the glandular system is less apt to become involved.

An article of his, on the use of "Cimicifuga in Chorea," which appeared in the *MEDICAL AND SURGICAL REPORTER* a few months ago, was mentioned, and he was questioned as to the dose and preparation. He uses the infusion, giving a teaspoonful three times a day, gathering the root in the early autumn and preparing it himself, thus being sure of a *reliable* preparation. Two other articles of his which have recently been published—"Sumach in Stomatitis" and "Quinine in Pneumonia," both in the same journal as the preceding—were mentioned and discussed at some length. And so one subject after another was brought up, and we all listened eagerly to the opinions of a man who for nearly sixty years has been practicing medicine in this quiet country place, and for more than half that time has been an acknowledged leader in the profession, clearly demonstrating that prominence and great intellectual development are not confined to those who dwell in the city, boast as we will of its superior advantages.—*N. Y. Med. Journ.*, August 6, 1887.

The Element of Truth in Popular Beliefs.

Dr. T. Lauder Brunton recently gave a lecture on the subject quoted above before the Royal Institute of Great Britain. The following is an abstract of his lecture:—

The common saying "Seeing is believing" gives a clue to the origin of many popular delusions, for the evidence of our eyes is by no means to be trusted, and unless corrected by the observations derived from other senses will often prove deceptive. Some popular beliefs are correct in regard to fact, but erroneous in regard to interpretation. Some others, which in their present form are absurd, are the survivals or modifications of other beliefs which were true.

In endeavoring to discover the element of truth in many belief we may be aided by tracing its history backwards in time, or by comparing it with allied forms of belief in different places.

As an example of the historical method we may take the belief that horse-flesh is unfit for food, a delusion which arose from the circumstance that horse-flesh was unfit

for Christian food, inasmuch as the horse was sacred to Odin, and eating its flesh was a sign of paganism.

As an illustration of the comparative method we may take the belief that a person cannot die if any door in the house be locked. Other forms of the belief are that a person cannot die as long as the doors or windows of the room in which he is lying are closed, and observation enables us to ascertain that this is due to the fact that the room is thus kept warm, and life therefore prolonged.

The belief that disease may be cured by hanging up rags in a sacred place may be connected by intermediate forms with the fact that infectious diseases may be conveyed from one to another by articles of clothing.

Some omens probably have an historical origin. Others depend on physical conditions, such as stumbling on leaving the threshold as an indication of coming misfortune. This may be regarded as simply an evidence of a deficiency in the motor power of the individual which may cause him to fail in an emergency.

Others again may be referred to indistinct sensations or subconscious conditions. Dreams are frequently influenced by the circumstances of the dreamer, either at the time or some days before, and hallucinations as well as visions of ghosts and fairies may be regarded as forms of waking dreams. The signs which were regarded in the Middle Ages as distinctive of witchcraft are now looked upon as symptoms of hysteria, and the condition of hysteria may perhaps be defined to be one in which impressions originating within the body itself tend to overpower those transmitted from without by the usual sensory channels.

The phenomena of thought reading and of the divining rod may in many cases be explained by the fact that sensory impressions may be received and may lead to action without rising into complete consciousness in the individual who receives them.

A Pessimistic View of American Medical Literature.

The country that has a Fourth of July, a Declaration of Independence, and an American Eagle, the country that gave birth to the telegraph and the telephone and stump oratory, can afford to have more medical journals than all the world besides; but it is questionable whether the immature observations and hasty conclusions that characterize the great mass of literature will redound to the power and glory of American medicine.

A fog of uncondensed experiences hovers over our consciousness like an atmosphere of uncombined gases. The sanguine and imaginative rush into print with their hopes and impressions. We are periodically startled by new theories and new remedies, or new virtues in old remedies; but it turns out at last that a will-o'-the-wisp flitting over a bog has been mistaken for a beacon light upon a hill. But shall we not record facts? Certainly, but first ascertain that you have one. Fact! that omnipotent monosyllable, has been the patrimony of cheats, and the currency of dupes from time immemorial. Facts have furnished the basis of the most stupendous delusions of medical history. The miracles of the Temples of Æsculapius, the cures wrought by the metallic tractors of Perkins, the Royal touch, Bishop Berkeley's tar water, homœopathy and mind-cure have all been sanctified by an irresistible array of stubborn facts. The focal adjustment of each individual is arranged to a different scale—no two ever look at the same object at exactly the same mental angle, and the faculty of correct observation, and the power of grasping a complex subject, articulating it distinctly and of treating it not only with effect, but luminously in its widest bearings and in its most intricate details, is the rarest and most exalted attainment of the mind.—Dr. W. S. Thorne, in the *The Pacific Medical and Surgical Journal*.

The Mortality of Physicians.

According to the experience of the life insurance company of Gotha, out of the whole number insured, there was a mortality of 11.53 per cent. Infectious diseases, diseases of the lungs, and apoplexy preponderated. Of the infectious diseases, typhus carried off a part of the younger physicians. Of ten hundred and fifty-two deaths, there was only one from poisoning by a dissecting wound, but nine other cases of blood poisoning; eight of erysipelas, one hundred and fifteen of typhus, fourteen by suicide, and four of melancholia.—*Deutsche Medizinisch-Zeitung*, June 20, 1887.

A Solvent for Antifebrin.

Dr. Proegler, of Fort Wayne, Ind., states that he has used the aromatic spirits of ammonia as a solvent for antifebrin, and has found it very good for that purpose. It was suggested to him by Mr. Louis Schmidt, a pharmacist of that city.

Clairvoyante Diagnosis.

A physician in this city recently had under his care a case of typhoid fever. As the patient did not progress very rapidly toward recovery an officious relative consulted a notorious clairvoyante regarding the patient. She affected the usual "trance state" and gave the following curious diagnosis which was copied by her daughter, who acts as amenuensis: "As I examine your case I find the membrane of the head has a watery fluid secreted in the membrane, which produces a sort of confusion and a roaring at the ears. The blood seems to loose its force of blood as it reaches the base of brain. this is caused by the strings of the kidneys drawing on the spinal nerves. this also is the cause of pain about the shoulder. I find both kidneys have been strained and the casings swell. I find the liver congested and filled with slime. this at times passes to the stomach, windpipe, left lung and throat. The left lung settles on casing of heart. I find a watery fluid between the heart and casing which causes the right ventricle and centre valve to be weak. The cough is caused by the left lung settling on the stomach. The stomach I find has been weakened by medicine, and I find a sort of white powder secreted in the casing of stomach and membrane of bowels, which is the effect of medicine. I find a little difficulty with bladder. I find a catching pain from hip to knee which has been caused from kidneys. I find the blood in a stagnant state, and the blood only quivers through the limbs.

"Take No. 5 with 10 Stomach Drops 5 times a day, and Tea of Sweet Balm and Poor Robin's Plantain."

As the clairvoyante had described only one symptom—the cough—in the case, the prescription was turned over to the attending physician.—*Buffalo Med. and Surg. Journal.*

Scarlet Fever in a Horse.

A case of scarlet fever in a horse is reported from Mechanicsville, Cedar county. If the attending veterinary surgeon is correct in his diagnosis, the case is a remarkable one. We hope to give the facts in the August *Bulletin*. That the disease exists in cattle has been demonstrated in London, England, where a herd of dairy cattle were infected for nearly two years, causing a large number of deaths of children and adult persons, from using the milk. The entire herd was destroyed and there was no further appearance of the disease.—*Bulletin Iowa State Board of Health*, July 15th, 1887.

One Point of View.

At the last meeting of the Orange County (N. Y.) Medical Society, Dr. Pillsbury, chairman of the nominating committee, was interrogated as to the omission of a delegate to the American Medical Association upon the ticket, whereupon he replied:

"The Society formerly sent a delegate to the American Medical Association. The American Medical Association no longer recognizes us as members of the profession under its code. The great State of New York is thus practically without representation in the National council. I think we are justified in emphasizing the remark—so much the worse for the National council. We trust the loss may be sanctified to them for their medical and spiritual good, and that when those who are too old to learn have slept with the other grandfathers of medicine, and those who grow up find wisdom, they may not be too proud to acknowledge and confess to the end that they may obtain forgiveness for the sins and follies of their youth. And what is the matter with us? The New York State Medical Society, and the societies in affiliation therewith, have declared their willingness to clasp hands with all physicians whose learning and good repute obviously entitle them to the recognition demanded by the country in this age so famously enlightened."

Tannin Test for Drinking Water.

Dr. Hager, in 1871, used a clear solution of tannin. Pour a tablespoonful of the solution into a tumblerful of the suspected water. If no turbidity occurs within five hours the water is good, if turpidity occur within one hour the water is decidedly unwholesome.

Colleges in Good Standing.

At the quarterly meeting of the Illinois State Board of Health, held July 8th, 1887, the following resolution, offered by Dr. Clark, of the board, was adopted: *Resolved*, That the phrase, "medical colleges in good standing," in the first section of the Act to Regulate the Practice of Medicine, approved June 16, 1887, is hereby defined to include only those colleges which shall, after the sessions of 1890-91, require four years of professional study, including any time spent with a preceptor, and three regular courses of lectures, as conditions of graduation, and shall otherwise conform to the Schedule of Minimum Requirements heretofore adopted by the board.

"Ode to Bacillus."

Oh, powerful Bacillus,
With wonder how you fill us,
Every day!
While medical detectives,
With powerful objectives,
Watch you play.

In epidemic glanders,
In certain forms of "janders,"
You delight.
E'en to the fifteenth culture,
Voracious as a vulture,
You can bite.

Koch and Spina growing splenic,
O'er your power so septicæmic,
Rant and roar.
Schmidt says when pus grows rotten,
Only then you are begotten,
Not before.

In lung tuberculosis,
In skin necrobiosis,
How you squirm.
While gonorrhœal burning,
Is caused by sporules turning,
Some affirm.

'Tis said a crypto-coccus
Will very often choke us,
If we fail
To drop the acid phenic—
Which is antisepticæmic,—
On its tail.

Freire says in fever, yellow,
He finds a little fellow
Breeding pest.
Gregg swears, do what he will, he
Sees nothing but fibrilli,
By his test.

In atmosphere mephitic,
In poison diphtheritic,
How you revel!
In earth and air and ocean,
You keep disease in motion,
Like a devil.

But Bacillus, Oh! Bacillus,
You try in vain to kill us,
Yet we thrive.
And though you try to blind us,
Yet, next year I hope you'll find us
Quite alive. —*Unknown Poet.*

Effect of the Hot Weather in Brooklyn.

Dr. Young, Registrar of Vital Statistics, of Brooklyn, speaking of the heavy mortality there in one week recently, chiefly from the oppressive heat, says, out of a total of 564 deaths, 373 were children under five years of age, and of these 91 had not passed their first year. Two hundred died of diarrhoeal complaints. The mortality for the week was at the rate of 38.82 per annum out of every 1000 of the population. Last year it was 33.34. The Doctor also says: "There are

few who have any idea of the suffering of people who live in these tenement houses during this fearful weather. It is hard to blame them for sleeping on fire escapes and the roofs, when their small rooms, in which perhaps washing and ironing are daily occupations, are veritable ovens."

Unwholesome Milk.

A large share of the mortality from diarrhoeal affections must be attributed to the use of unhealthy milk. In Holland, she asses are driven about the streets and milked before the houses where bottle-fed infants are found. It is said that the mortality among children thus nourished is exceedingly low. Competent authorities state that next to the milk of the mother, that of the ass is the best adopted to the infantile digestive organs. But asses' milk is not obtainable here, and even in Paris it brings \$1.50 per quart. We are accordingly obliged in cities to content ourselves with milk which is supposed to have been derived from the cow. It is absolutely impossible to obtain fresh milk, and we are extremely fortunate if we can procure that which has not undergone partial decomposition.—*Dr. Campbell, in Buffalo Medical and Surgical Journal, July, 1887.*

What is Pain?

We all know what pain is, says the *Popular Science News*, but to give a scientific definition of it has taxed the brains of lexicographers and encyclopædists. An eminent physiologist calls it "an excess of the sense of touch;" and another "hyperæsthesia of the sensory fibres." Dunglison, in his *Medical Dictionary*, says it is a disagreeable sensation, which scarcely admits of definition;" and Gardner, in his work of the same title, under "Pain," says "See Dolor;" and, turning to "Dolor," we find it concisely explained as "pain." The great French *Dictionnaire des Sciences Médicales* coolly and conveniently tells us that to define it is superfluous. Professor Erb, in *Ziemssen's Cyclopædia*, after some discussion, comes to the conclusion that pain is a new sensation, experienced when excitation of the nerves reaches a certain intensity." Perhaps the *Imperial Dictionary* covers the ground in describing it as "an uneasy sensation in animal bodies, of any degree from slight uneasiness to extreme distress or torture, proceeding from pressure, tension, or spasm, separation of parts by violence, or any derangement of functions."

Contraindications of Nitro-glycerine.

When headache and neuralgia occur in patients with chronic congestion of the subcutaneous veins of the face, nitro-glycerine is to be avoided; and similarly it is of no use in asthma, when the face is reddened in consequence of emphysema. If however, a pale face exists with angina pectoris, migraine, giddiness, shock, toothache, or seasickness, the best results may be looked for by giving nitro-glycerine.—*Lancet*.

Never Ask How Much.

"Take my advice, and when you get a prescription put up at a drug store never ask how much it is," said one gentleman to another the other day. "Why not?" he was asked. "Because the clerk will 'size you up,' as the boys say, guess how much money you have got, and charge you your pile." "What do you advise?" "Just this. When the urbane compounder of medicines hands forth your prescription, just look wise and lay down a quarter. Now the chances are that the drugs in the preparation don't cost over a dime. He will look at the quarter, study a minute, and then make up his mind that he has been foolish enough to sell you the same dose for 25 cents at some past time, and he'll take it and not say a word. Lay down a dollar, however, and it will be just the same—no change. Try it and see."

Items.

—The Arab who invented alcohol died 900 years ago, but his spirit still lives.

—It has been discovered that chrome yellow is extensively used to color "noodles."

—A farmer sent \$10 to a city advertiser for the best feed-cutter and got a \$2 set of teeth.

—One hundred and sixty-five people died in Chicago, July 15, 16, and 17, from the effects of heat.

—One of the best things about Mr. Lawson Tait is that he declines to "talk shop" at dinner.

—An Austrian doctor advertises to pay one-half the funeral expenses in cases in which he is not successful.

—A printer up in Canada is said to be 103 years old. He has made so many typographical errors during his career that he is afraid to die.

—Fifty thousand tons of soot are taken from the chimneys of London annually. It is valued at two hundred thousand dollars, and is used for fertilizing purposes.

—To exterminate the rabbits, which have become a plague in Australia, it is proposed to propagate a contagious disease among them, and the experiment is to be first tried on Torren's Island.

—The number of insane patients committed to the Flatbush Asylum, New York, for three weeks of July was 56, and the total for the month is likely to reach 70, which is considerably in excess of the highest number of commitments for any one month in the history of the department. The physicians are disposed to impute the large increase to the protracted excessive heat.

—Two men have been arrested in Rochester, N. Y., on the charge of violating the revenue law in selling wine without a license. They testified that they sold to saloons about 100 gallons of a drink made by this recipe: Put about 16 gallons of water into a common wash-boiler, add 48 pounds of sugar, 1 pound of tartaric acid, and some anilin dye for coloring. After stirring with a stick until dissolved, add a quantity of orris root, cut with a pint of alcohol, to give the flavor of raspberry wine. This stuff has been sold for more than a year as wine.

There have been no changes in the Medical Corps of the Navy for the week ending Aug. 13, 1887.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from Aug. 7, 1887, to Aug. 13, 1887:

Major J. C. McKee, Surgeon, ordered for duty at Watertown Arsenal, Mass. S. O. 101, A. G. O., Aug. 6, 1887.

Major H. E. Brown, Surgeon, sick leave extended to Aug. 6, 1887, on account of sickness. S. O. 184, A. G. O., Aug. 10, 1887.

Major P. J. A. Cleary, Surgeon, ordered to Ft. McDowell, A. T., instead of Ft. Assiniboine, M. T. S. O. 180, A. G. O., Aug. 5, 1887.

Capt. John M. Dixon, Asst. Surgeon, died Aug. 8, 1887, (station Ft. Mason, Cal.)

Capt. J. C. Morrill, Asst. Surgeon, ordered from Ft. Klamath, Oregon, to Waterlist Arsenal, N. Y. S. O. 181, A. G. O., Aug. 6, 1887.

1st Lt. Wm. E. Hopkins, Asst. Surgeon, ordered from Angel Isl'd, Cal., to Ft. Mason, Cal. S. O. 104, A. G. O., Aug. 10, 1887.

1st Lt. C. N. B. Macauley, Asst. Surgeon, promoted to be Asst. Surgeon, with the rank of Captain, by operation of law, Aug. 10, 1887.

1st Lt. J. E. Pilsher, Asst. Surgeon, ordered from Ft. Monroe, Va., to Ft. Wood, N. Y. Harbor. S. O. 180, A. G. O., Aug. 5, 1887.

1st Lt. C. S. G. Anderson, Asst. Surgeon, (station Whipple Bks., A. T.,) ordered to Ft. McDowell, A. T. S. O. 81, Dept. Aug. 3, 1887.

1st Lt. Wm. A. Suter, Asst. Surgeon, ordered to return to Washington Bks., D. C., on the breaking up of the Camp at Creedmoor, N. Y. S. O. 166, Div. Atlantic, Aug. 10, 1887.

CEREBRAL LOCALIZATIONS.

BY E. P. HURD, M.D., NEWBURYPORT, MASS.

The peripatetic phrenological professor, presumably long since dead, though lingering in our memories of bygone days, could he come to life would doubtless be appalled at the havoc which modern cerebral topography has made with his specialty. The old "bumps," as indices of character have disappeared from the surface of the cranium, and instead thereof we have certain tolerably well defined motor and sensory centres in the cerebral cortex, while the functions of whole regions (as the frontal lobes) are still a matter of speculation.

Professors Nothnagel and Naunyn, at the recent medical congress held at Wiesbaden (April 13-16, 1887), made known the results of their studies in cerebral localizations. Naunyn, by the way has previously done good work in this department of nervous diseases, and Nothnagel has published the best treatises yet written on diagnosis as based on the doctrine of cerebral localization. From the addresses of these two authorities we shall endeavor to sum up the present status of the question.

The first great discovery was that of Broca respecting the seat of aphasia in the third left frontal convolution, known as Broca's convolution.

After this discovery, cases of aphasia were reported in which lesion of Broca's centre were said to be absent, while other neigh-

boring parts of the cortex were found diseased. It was hence concluded by certain English physiologists "that it was only 'ataxic aphasia' which was caused by lesion of the third left convolution, and that there is still another form of aphasia, connected with lesion of other cortical regions, which form is characterized by the loss of verbal images." It is noteworthy that subsequent investigation has completely confirmed this view. In 1874 Wernicke proved that this second form of aphasia, characterized by loss of the comprehension of words, is located in the posterior two-thirds of the superior temporal convolution. In 1877 Kussmaul characterized this second form of aphasia as accompanied with a verbal deafness. Naunyn affirms that his own observations, 70 in number, go to prove that making some allowance for some individual differences of structure, and occasional substitution of function by the right hemisphere, both sensory and motor aphasia have the seats originally assigned to them by the authorities named.

Nothnagel, in analyzing the facts which have a bearing on the localization of the sense of sight, mentions the following visual troubles as associated with definite lesions of the occipital lobe:

1. *Hemianopsia*—blindness in the homogeneous parts of the visual field. If the cortical lesion which produces this blindness be bi-lateral, there is (2) complete *amblyopia*. In (3) *mental blindness* (*seelenblindheit*), the eye sees, but there is no comprehension of what is seen; the patient has lost his visual memories. This affection is linked to definite lesions (destroying lesions) of the

occipital lobe. (4) *Daltonism*. This is sometimes associated with mental blindness, but may exist separately. (5) *Hallucinations of sight*. These may also be due to cortical lesions.

"There have been a sufficient number of autopsies," says Nothnagel, "to prove that these disorders are connected with lesions of the occipital lobe." In answer to the question: "What part of the occipital lobe presides over the visual function?" Nothnagel affirms his persuasion that it is chiefly the cuneus and the first occipital convolution (O_1). In pronounced cases of hemianopsia, the lesion almost always exists in both regions mentioned; on the other hand, hemianopsia is wanting if O_2 and O_3 are alone the seats of lesion.

As for the seat of *intellectual blindness*, in which all the visual memories of objects are abolished, Nothnagel finds reason for locating it in the gray matter of the occipital lobe, abstraction being made of the cuneus and O_1 , which he thinks have nothing to do with this particular function. How much of the occipital lobe is concerned with visual memories is not known.

Localization of the motor function.—It is generally admitted that lesions of the cortex cerebri produce troubles of motility, but the cerebral localization of all the muscles of the body has not yet been determined. The essentially motor regions are the central convolutions and the paracentral lobule. Whether these portions of the hemispheres be the absolute, or only the relative motor field for certain groups of muscles (*absolute Rindenfeld of Exner*), certain it is that monoplegia is generally found associated with a circumscribed lesion of these regions.

Localization of the muscular sense.—Nothnagel considers it sufficiently proved by what he calls "old stationary foci of deficit" ("destroying lesions") that the centre of the muscular sense is in the parietal lobe.

Troubles of the sensibility.—There is almost everything yet to be learned about the localization of different kinds of sensibility. Paralysis due to cortical lesion are generally accompanied by diminished sensibility of the parts paralyzed; but there seems to be no correlation between the intensity of the motor disturbance and the modifications observed on the part of the sensibility. Certainly the existence of hemianæsthesia has generally been found to be dependent on lesions other than those of the cortex cerebri, as of the internal capsule.

Nothnagel concludes his paper by passing judgment on the following questions:

1. "Do paralytic and other troubles of cortical origin result in fact from cortical lesions, or from lesions of the underlying medullary substance?" "Fifteen years ago," he says, "doubt was warranted on this question; to-day we have a sufficient number of conclusive observations to authorize us in deciding in favor of the cortical origin of these disorders."

2. "Is it the ganglionic cell or the fibres of association which must be regarded as the seat of the lesion?" Practically, he says, it makes but little difference which view of the case you take. Theoretically, the lesion of the ganglionic cells suffices to explain the abolition of function in the centrifugal conductor, as well as in the centripetal conductor.

3. In answer to the question: "Is there any such thing as functional substitution in the cerebrum?" he says; "not for the paralytic and other troubles resulting from permanent destruction of the cortical regions presiding over the function in question." We must bear in mind, he continues, that paralysis may be inhibitory, and disappear with the irritation which produced them, or the loss of function may be temporary from lesion of some *relative* centre, and not of an *absolute* functional centre (Exner).

"The existence of localizations is no longer open to doubt. But how shall we explain the cortical function? The gray substance is the seat of the psychical functions, and as the centres presiding over motility are also in the cortex, the term *psycho-motor centres* has come into use, the understanding of this term often being this, that the internal representation of the movement is identical with the impulse given to the centres of the said movement. This view is certainly erroneous. The muscular movement depends on circumscribed centres, but not the production of the *image* of the said movement. A man who has suddenly become blind by an embolus retains his visual images; he cannot acquire new ones, but the old remain. I believe that the cortical region for motor images is in the parietal lobe, while the motor region is the *gyri centrales* and the paracentral lobule. The motor centres are agglomerations of cells into which is conveyed the impulse to movement by the association of fibres from any part of the region of motor images. Hence it is, that simple muscular paralysis results from the destruction of the motor centres, intellectual paralysis (*Seelenlähmung*) from

that of the regions of motor images; the psychical process has for its seat the entire surface of the cerebrum."

It may seem to many readers that the above somewhat rapid resumé of what is known respecting cerebral localizations leaves vast regions still unexplored. This is true, but it also indicates the direction in which progress is being made, and must still continue to be made.

One thing has been clearly brought out by late discoveries; the distinction of *partial memories* has become a settled fact; to every sense corresponds a memory which has a definite seat in the cerebral cortex, which may be destroyed by disease; on the sum of these memories largely depend character and conduct.

NOTES ON THE TREATMENT OF SOME COMMON UTERINE AFFECTIONS.

BY JOHN AULDE, M. D., PHILADELPHIA.

Among the numerous difficult and intractable cases which the general practitioner meets in his daily rounds, probably none are more troublesome in their solution than the more common class of uterine affections; and the object of the present paper is to place the matter before the reader in such a light that there will not be further necessity for condemning the poor sufferers to a life of pain for the want of appropriate treatment. To this end a few simple measures may be easily carried out by any physician, with satisfaction to himself and with the greatest benefit to his patient. So long have these affections been overlooked or disregarded by the family physician, that the patients have been compelled in self-defense to seek relief from specialists; and although the specialists in their particular departments have done their work thoroughly, a very large proportion of the patients have been unable to avail themselves of these advantages, either from lack of financial ability or from fear that some formidable operation would be proposed.

These cases have been regarded as the *opprobrium medicatorum* for generations past, and have been facetiously referred to as "internal, infernal and eternal;" but the time is now when the physician who resists the appeals for relief will certainly be the wiser by the loss of his patrons.

Much has been written and printed in regard to cases of this class, and it would be difficult to find a single medical journal without a flaming advertisement of some infall-

ible "uterine tonic," or a "universal pessary guaranteed to cure all the ills that fall to the lot of this much abused organ. No one will condemn any legitimate operation which scientific skill demands; but for one, I must protest against unsexing a woman on mere suspicion that the womb and its appendages are at the root of her troubles. I call judgment on this question, and believe that the conservative element of the profession will uphold me in this claim by its unqualified approval. But I shall lose sight of the object of my paper, which is not to condemn but to praise. Let me therefore proceed to a consideration of the subject in hand, and if the occult business is made clearer and more simple to a single practitioner my duty will have been fully discharged.

Believing that an attempt to designate the cases which follow by technical terms would in a measure detract from the real interest in its perusal, it is deemed advisable to confine the descriptions or histories to those general terms which, while being thoroughly understood, will at the same time admit of the introduction of other material as concomitant factors bearing important relations to the various cases. This method will readily be seen to be the more acceptable from the fact that but few of the diseases seen in practice compare favorably with the book cases. It is an exceedingly rare thing to find any of these cases without complications, complications which frequently overtop the malady for which the patient desires to consult you; and as these notes are selected casually from my visiting list, they are so arranged that different classes will be distributed where they belong, although it is readily seen that my collection is far from complete. I have studiously avoided selecting any but those cases which will properly come under the heading of my paper.

First Class.—*Case 1.* About four years ago I was consulted by a widow lady, aged 47, for what she had been told was "falling of the womb." She had reached, but had not passed that critical period known as the *menopause*, and although she had consulted half a dozen doctors, both male and female, she had lived the life of an invalid for more than twenty-five years. She showed me a spot, somewhat dark and distinctly red on close inspection, on the the left temple, which appeared to be an epithelioma, but she did not care much about that if she only could be made well enough to walk about and attend to her household duties. The reason for consulting me was stated to be on account

of a peculiar attack of numbness which had occurred a few weeks previously, the whole right side being affected, though only for a short time. Similar attacks had occurred previously, but none of the severity of this last one, and she desired to know how soon she would be likely to die from paralysis. It was not without some words of encouragement that an examination was permitted, as she told me frankly that she only wanted to take some medicine that would do her good.

Physical examination disclosed the uterus low down, the os eroded, with a granular cervix, but protruding in front of it, and external to the body, there was a pouch nearly as large as a hen's egg, apparently covered with natural skin, which was in reality the upper floor of the vagina (cystocele). Treatment consisted in the local application of Churchill's tincture with a glycerine tampon, until a suitable instrument could be obtained. I should have stated that there was a history of one or more hemorrhages; and this together with the suspicious scar on the temple, led me strongly to suspect that the cervical granulations were malignant in character. I was further inclined to this belief from the fact that there was a history of cancer in the family, but as a counter-indication I had before me a well nourished and healthy woman. She was not altogether healthy, however, as she frequently complained of pain in the cardiac region and there were the usual indications of tension at the radials (endarteritis). The attempt to use a tampon proved a failure, just as preceding attempts at the use of a pessary had done, several of which she showed me.

What is to be done in this case? Here is a patient who ought to be able to enjoy life for many years to come, and it is evident that should the menopause be passed without any serious accident, and the cystocele overcome, her future presents many features of encouragement, even after her case has been given up by the physicians whom she had previously consulted. Would it be advisable to attempt an operation for the cystocele? I think not, in her present condition. Will she be likely to make any perceptible advance towards health by internal medication, so long as this difficulty remains? It is extremely doubtful, and for the simple reason that she cannot take the exercise requisite to maintain a good standard of health. It is necessary, therefore, to adopt palliative measures for the relief of this trouble, and what is more clearly called for than a suitable pessary? But she has already had a trial of half a dozen, and all

of them were failures. After looking the ground over, I decided that Dr. Stauffer's "Stem-ball instrument" was the only one which presented any reasonable prospects of success, and accordingly one was procured and properly adjusted. The name of this instrument sufficiently indicates its character, but I may mention the points which prompted me to make this selection. First, it is wholly supported outside the vagina, so that none of the abdominal tissues suffer from undue pressure. Second, a belt is applied below the umbilicus, to which are attached rubber tubes passing through eyelets in the lower end of the stem, freely movable, while on the upper end of the stem is screwed a ball, the size of which is to be regulated by the amount of displacement necessary. Third, the length of the stem is to be determined either by actual measurement or by trial, and when one of these instruments is used care should be taken that the patient understands the use and value of hot water irrigations daily. Fourth, the ball of the instrument rests in Douglass' cul-de-sac; and if not too great pressure is made against the tissues, and hot water is freely used, but little discomfort is likely to arise after the first two weeks. It can be laid aside at bed-hour and reapplied each morning.

Some years ago I invented an instrument for the exact determination of pessaries of this class, by which any physician could take the patient's measure, just as the shoemaker takes the measure for a pair of shoes, or the tailor takes the measure for a suit of clothes; but thus far I have never published it, believing that I was doing a good service to suffering humanity by withholding it. It is called an "Intro-vaginal Pelvimeter."

In this case, however, the Stauffer instrument answered every requirement, and with suitable local treatment along with internal medication she made a good recovery, and to-day, with exception of the need for the use of the pessary she has excellent health.

Case 2. About a year ago, a lady aged 52, consulted me for "falling of the womb;" saying that she had suffered for about twenty years, and that the family physician and several others had treated her frequently, but without any benefit. On examination I found the uterus as large as a goose-egg, pendulous between the thighs (procidentia uteri). The organ was readily replaced. Her main dependence had been bandages; the last attempt at treatment having been such a failure that she had become disheartened. The circumstances related to me were

that a physician had promised her absolute relief, and that after making an examination he procured a pessary (Smith's), and had called at the residence to introduce it, but when she subsequently arose to bid the doctor good-day, the instrument dropped on the carpet. This accident happened to patient No. 1, and it became a serious embarrassment when she dropped the support on the floor or in the street. The same kind of a contrivance as that first described answered admirably in the case No. 2.

Second Class. Having used a number of these instruments with equally satisfactory results, I cannot deny them that meed of praise to which they are justly entitled, but I venture the suggestion that in many cases pessaries are a hindrance rather than an advantage to patients, and where it is possible to avoid their use far better results may be anticipated. Several of the cases which follow will fully illustrate this point, while others will demonstrate the advantages of not using them at all.

Case 3. In the month of December, 1885, I was called on to visit a lady who had become bed-ridden by the use and abuse of pessaries. The circumstances of the case are about as follows:

Mrs. C. had been under the pessary administration about four years, but in the meantime had given birth to a child, then nearly two years of age. She was now twenty-seven years old and had generally enjoyed good health, but four years previously her medical attendant had advised the use of an internal pessary, which she unfortunately wore too long. It gave her but little benefit, but it was supposed to give her no trouble further than keeping up a constant discharge, but, innocently thinking it was all right because the doctor had put it there, the instrument was allowed to remain in situ until after pregnancy had continued for some time. A short time after the birth of the child the old feeling of weariness coming on, it was deemed wise to have another pessary introduced. The result, however, was not at all satisfactory, and another physician was consulted, who, probably thinking that his services would not be appreciated unless he did something, said, "yes, the pessary was one that could be improved upon by making an exchange," and accordingly the exchange was made. No relief having been afforded by this manœuvre, a third physician was called in, who, by the way, has a *penchant* for the discovery of possible tumors. To meet the early advance of any possible tumors, heroic measures were at once adopted. The uterus

was promptly scarified and freely leeches, while carbolic acid was used internally in such strength that the pain became constant and almost unbearable.

The *finale* was fully intended to be a master-stroke, and a supreme effort was made to win the patient over by faith, when a cup-pessary was introduced, with the firm assurance that the prospects for the future were the brightest, and that all pain and suffering should henceforth be things of the past. Confidence in this prophecy was visibly shaken when, in answer to a direct question by the patient, the attendant admitted that he did not know what ailed her. Friendly relations with this physician were severed, and an irregular physician consulted. He, also, said "yes," and ordered an abdominal electric bandage or belt, not forgetting to deliver a few sugar pills, and predict an early and rapid convalescence. Six weeks passed without shedding a ray of hope in this once happy home, and the poor woman began making arrangements to die; but that feeling, "which lives eternal in the human breast," buoyed up the husband to such an extent that he decided to get another doctor.

At this critical period I arrived on the scene of desolation, and the appearance of this poor patient was indeed pitiable in the extreme. Emaciated, hollow-eyed, unable to stand or walk, and unwilling to be further tortured, she appeared "sunk to the bottom of abjectness." Notwithstanding kind words of encouragement, she positively declared that she would not make one single effort herself, nor would she permit anything to be done for her which should in the least add to her sufferings. She had not walked across the room for weeks without assistance, did not dare to attempt to go up or down stairs, and when she tried to stand up she endured the most agonizing sensations. To use her own words: "It seemed as if the whole universe was expanding, and that she was going out with it." After expanding up to a certain point everything became indistinct, when she would have to lie down again. The conditions were anything but favorable, and it seemed that she would persist in dying, in spite of my most earnest solicitations.

Physical examination discovered an enlarged yet moveable uterus, the cervix choked with detritus from the uterine cavity, along with the debris from the use of the carbolic acid in the cervical canal. Treatment locally consisted in the use of boric acid with a cotton wool tampon, allowed to remain say three days, when it was removed, the vagina

thoroughly irrigated with hot water, and a new application made. In less than a week this patient was able to go around the house, and in two weeks she was able to go out, and at the expiration of three weeks from time treatment was instituted her servant was dismissed and she commenced to do her own housework. Internal treatment was also continued for a time, as was the local treatment, varied from week to week, as was indicated, the result being perfect recovery. I should make a note here of an oversight, one which may possibly happen to others. I have stated that she was instructed in the use of hot water irrigations, but it was not until the end of the second week of treatment that I learned that all she had in the way of a syringe was a glass instrument, and since then I have made it a rule to examine and test the workings of these instruments before the patients undertake to use them. This will be found an excellent plan, and where patients do not have them on hand it will be found most satisfactory for the physician to supply them himself, in which case he knows just what the patient is using. The history of this case appears to point to unfortunate effects from the use of pessaries, while the evidence is conclusive as to the favorable issue following the most simple method of treatment which it is possible to inaugurate. How much more satisfactory these results are may be inferred from a brief history of the case which follows:

Case 4. Over two years ago a lady sent me a message to the effect that when she could walk to the office she intended to consult me for some supposed uterine trouble. Not long after she consulted me in regard to her child, and told me then that she had never fully recovered since her last confinement, a condition of affairs entirely too common at the present day. Later I saw her at the office, and found her suffering from uterine engorgement. The os was patulous, the interior of the cavity unusually large, along with a catarrhal affection of the uterine mucous membrane (sub-involution). Treatment was conducted on the same plan as that just described, with the addition of tonic remedies for the stomach and the uterine functions, and although her visits were somewhat irregular, she made a perfect recovery. I should note in regard to the irregularity of the visits, that they were discontinued from time to time of the patient's own volition, as she said, "to see if she could not get well without the doctor;" and during these intervals she was industriously running the sewing machine. In the treatment of this case, I

desire to note the most favorable results from use of a paste having incorporated in it iodoform, the base being lanoline. Instead of cotton I now depend altogether on wool for the tampons. The antiseptic wool is far superior to cotton, for the reason that it does not collapse when moisture comes in contact with it, while the lanoline brings it back to nearly its original condition when on the sheep. Its value will be appreciated in the case which follows; but I cannot leave this one without noting the great temptation there was to use a pessary. Had I done so it is evident to me now that the patient would have secured temporary relief, and in the course of a few months would have returned to me or sought some other physician in a condition far worse than at first.

Case 5. Mrs. B. is a sprightly little lady of 27 summers, married five or six years, but has no children. For the past two years, however, she has apparently lost all her sprightliness, and thinks she is getting old too fast. She has abdominal pain, pain in the back, suffers from constipation, and is compelled to go to bed for a day or two on the appearance of each menstrual molimen. Physical examination discloses the fundus of the uterus bent backwards and pressing on the bowel (retroflexion), thus accounting for the abdominal pain, and in part for the constipation, and for the pain in the back. The organ being freely movable, replacement by means of the sound was first practiced, then dilatation cautiously by the use of Baer's dilator, when a suitable tampon was introduced and allowed to remain several days. An Emmet pessary was introduced on trial, and seemed to answer very well; but as the patient lived at a distance and came here a month or two for treatment, it was not deemed advisable to allow her to depend too much on any kind of an instrument, when it was but a question of a few weeks when the trouble would probably be fully relieved. My anticipations were realized, the patient starting for her home feeling as well, if not better than ever in her life.

In all of the preceding cases it will be apparent that very little treatment was needed, and such is the case; but they were just such cases as make the bad ones when allowed to continue. When these simple cases are allowed to go on, shortly there appear ovarian troubles, with hysterical manifestations and attacks of syncope in their wake, when the real difficulties in the way of treatment occur. These simple cases are often permitted to go on even under treatment, as the following case exhibits:

Case 6. Mrs. C. is a care-worn looking, but cheerful lady of twenty, but she complains of headache, abdominal pain as well as pain in the back, and altogether she looks as though she was pretty well washed out. Married several years, but without children, she has little to do except her housework, but lately she is scarcely able to attend to that properly. For the past six months she has been under treatment at the hospital, where she has been treated locally once or twice a week. Not having made any perceptible headway during all of this time, she has concluded to change to a doctor in the vicinity, and comes to me in the hope of meeting with better success. Physical examination reveals a relaxed condition of the abdominal tissues, a state of affairs we would naturally expect to find from her general appearance. Along with the uterine affection there is bronchial catarrh, showing that an affection of the mucous tissues in one part of the body may be found reproduced in another and distant part, even when there is no continuity of surface. In this case the weekly use of a suitable tampon along with a tonic treatment quickly relieved her, so that in the course of a few weeks she was dismissed cured.

AN ETIOLOGICAL FACTOR IN THE
PRODUCTION OF A CASE OF
DIABETES MELLITUS, AND
ITS PROMPT SUBMIS-
SION TO THE INFLU-
ENCE OF CO-
CAINE.

BY E. K. WELLER, M. D., OF TREXERTOWN,
PENNA.

Mrs. Chas. W.—, aged 54. Farmer's wife. Family history good. She had been a strong, healthy, well-built and muscular woman and always worked hard. She has a light complexion and a nervous, active and excitable temperament. This has given her a quarrelsome disposition which has for long years made her married life one of continual strife, her husband having a similar temperament. Fright and worry were unknown to her. About three months ago she noticed that she began failing in health, her nerves became more unsteady, and she now began to be easily frightened and worry over trifles; the slightest excitement, as an accident to a horse, causing palpitation of the heart and dyspnoea. She also began to notice that her

eyesight was failing. In addition, there was itching at the vulva which increased to such a degree that at present it gives her great annoyance. Her present condition (May 5, 1887,) is as follows:

Appetite and digestion good and bowels regular. Tongue large, pale, flabby, and dry. Skin harsh, dry, and itching. Muscles flabby. There is considerable emaciation for her. The thirst is at times intense and almost continuously present. She sometimes consumes a quart of water in an hour. Occasionally there is tinnitus aurium. Eyes not examined.

The urine is passed in large quantities and micturition is frequent day and night. When a drop of urine is dropped on the oil-cloth it leaves a "salty" deposit on evaporation, and when left in a chamber over night ferments. The quantity passed in twenty-four hours is about two gallons, has a sweetish odor, and when boiled with an equal quantity of Fehling's solution, leaves a "brick-dust" deposit which, approximately estimated, constitutes about one-twelfth of the bulk.

Treatment.—Cocaine having a pacifying effect upon the brain and a most excellent remedy for the relief of polydipsia from other causes, I prescribed two drops of a four per cent. sol. every three hours, and the anti-diabetic diet advised by Tyson, in Pepper's System of Medicine.

June 7th, 1887.—After a few days the polydipsia disappeared and the urine was little above the normal quantity. The pruritus vulvæ was much less annoying. The itching and dryness of the skin was absent. The other conditions remained the same. I continued the same prescription, adding another for the anæmia and as a tonic, viz:

R Tr. opii.....f 3 j
Tr. ferri chlorid.....f 3 j

M. S.—Twenty drops three times a day in water after meals.

The patient ordered to return in two weeks.

I saw the patient again on the 28th of June when all the symptoms had disappeared. The anæmia was very much diminished, and she felt "as well as ever." The nervous symptoms had all improved and the palpitation of the heart has not recurred once. I now continued one drop of a two per cent. solution of cocaine, and the iron. After using this treatment for a month longer the case could be called cured, as all traces of sugar were absent when I made the last examination of the urine. I have since heard

of the patient, and there was no return of the symptoms.

I could at no time find any increase or diminution of the area of hepatic dullness on percussion, as reported in some other cases.

The etiological factor, which I want to refer to in this case, is arrived at by exclusion. In the absence of all others, none of which are definite, it appears to me that this case was caused by the reaction of over-active emotional centres on the diabetic centre.

Certain hypothetical inhibitory centres are recognized, and that the one controlling the glycogenic function of the liver is in close relation to the emotional centres seems logical, in this case at least; for whenever the patient became angered or excited the symptoms, and especially the pruritus vulvae, were aggravated. Now we know that the diabetic centre is in relation with the other special centres, notably the sexual, for diabetes mellitus has occurred in persons who are given to excess in sexual indulgence; so that, if sexual excess or over-activity of the sexual centre has induced such a degree of affection of the diabetic centre as to cause diabetes mellitus (as it has affected any or all of the emotional centres; for instance, giving rise to emotional insanity), then it is but logical to conclude, if no other cause can be demonstrated, that the excessive exercise of any emotional centre may react on the diabetic and induce diabetes.

The so far successful issue of this case under the influence of cocaine leads me to make the suggestion that it be carefully tried in similar cases.

While there are several drugs which have a decided and prompt action on this disease, there are some which are open to objections, and it is well to know several, so that for individual cases we may select the one that is least objectionable.

—It is stated that a very considerable quantity of injurious fungi is now finding its way into the market as mushrooms, and several cases of severe illness, caused by the consumption of what appear to be the button mushrooms, but which are really poisonous fungi are reported. These poisonous mushrooms have a yellowish appearance when cut, but otherwise appear exactly the same as the edible mushroom.

SOCIETY REPORTS.

Special report to the MEDICAL AND SURGICAL REPORTER by A. S. MCKEE, M.D.

MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD IN DUBLIN.

Address in Medicine.

BY W. T. GAIRDNER, M.D., LL.D., EDIN.

After introductory remarks, the speaker put forth what he called a "A curious inquiry," viz: "Has the practice of medicine (that is, the art distinguished from the science) made a single step since Hippocrates?" Such, alas, was the doubting, almost mocking query suggested by the late most eminent Sir William Hamilton, Professor of Logic and Metaphysics in Edinburgh University, in an article reviewing Cullen's writings, published in the *Edinburgh Review* in 1832, and afterwards reprinted in a volume of discussions, published in 1853, not long before the author retired from public duty. To this question, thus propounded by a distinguished and marvelously learned authority, Dr. Begbie then addressed himself with a great amount of Hippocratic erudition, by contrasting ancient with modern practice. The interval he endeavored to bridge over, from 400 B. C. to 1875, A. D., was quite too enormous to be so dealt with. Hippocratic medicine, after all, and nineteenth century medicine are not comparable quantities. It was much more easy to show that we knew more and that we cured better than Hippocrates and Galen. Dr. Begbie was most kindly disposed toward the ancients, and had no difficulty at all in showing that they worked marvelously well, and had anticipated us in several of the arts and inventions and observations which we are apt to call our own. It was Galen who built up the scattered fame of Hippocrates in the second century of the Christian era. For this, even if for nothing else, Galen would have the thanks of every student of medical history.

To Cullen and his age the speaker next devoted considerable time. Cullen was the recognized inheritor of Hippocratic ideas in Edinburgh. His fame was world-wide, not only in medical circles, but also in literary. There arose an antagonist to Cullen, whose system, Brunonianism, almost overturned Cullen and his views, and entertained the thoughts of medical minds at home, in Germany and in Italy, to an extent we can scarcely comprehend now-a-days. From what we know of the system, I doubt if two

men in the British Medical Association could, at this moment, give a reasonably clear, off-hand account of the doctrines termed Brunonianism. Such a system of the treatment and cure of disease as this system really was, if brought to light now, would be very short lived to what it was then. This I take as a proof that we are on a more solid foundation, and have made advances since that time.

In France, the new birth of pathological anatomy, represented by the great name of Bichat, at the very beginning of the nineteenth century, put a stop to all such vagaries as Brunonianism by furnishing a more tangible and real pabulum for the medical understanding. But it still lingered in parts of Italy, and an encounter of my own, in the great Ospedale Maggiore of Milan, in 1852, with one of the venerable professors, showed that the art of medicine had not advanced many steps there since the time of Cullen, or possibly even of Hippocrates. On this occasion he ordered every third or fourth patient to be bled.

To return for a moment to the Brunonian system of heresy, and the apparent defeat which for a time was inflicted upon the traditional or more orthodox medicine represented by Cullen, we see that although Cullen did his best for it, the art of medicine was in a condition of unstable equilibrium toward the close of the eighteenth century. The Brunonian theory substituted infinitesimals for the potent remedies of John Brown, and exactly the same remark may be made of the homeopathic doctrine, also a revolutionary child of the eighteenth century.

Have we attained to greater stability now? I venture to answer this question in the affirmative, but can dwell only on a very few points of salient interest in a vast field of inquiry, and simply show the direction of modern progress. The impulse given to surgery through antisepticism is one of the greatest in the history of the art. Yet we have eminent surgeons who obtain brilliant results without using these particular remedies.

In some minds the great revolution in the medical treatment of fevers and inflammations occupies as advanced a position as antiseptics in surgery. I am bound in candor to admit that while I have no doubt as to the advantage in some cases of the antipyretic or antithermic treatment, I have yet to be convinced of its application as a routine in typhoid or in any other fever. I am by no means insensible to the wonderful

patience, research and apparently scientific exactness shown by some recent authors, and it may be readily conceded that both in typhoid fever and pneumonia, as previously treated in German hospitals with an enormously high mortality, the method in question marks a great advance.

"The art of medicine is at this moment in a peculiar position. The day of orthodoxies is over, the day of real science is only just dawning. It is no longer possible to blame a man for having ceased to believe what our fathers believed; but it is extremely difficult to state in general terms what we believe ourselves, and still more difficult to forecast the future and lay the foundation of the faith of our successors."

Notwithstanding the apparently sceptical ring of these sentences, I hope to be able to show you how the new theory and corresponding practices which have replaced the old, are the results of applied sciences and not mere tradition, and thus secured against revolutionary overthrow.

1. *Hygienic Remedies.* The fruitful progress of preventive medicine (otherwise called sanitary science) during the last 30 or 40 years, is not only a striking advance in itself, but it may be maintained that curative medicine has steadily advanced along the same lines. The prevention and cure of disease are not identical, but the laws which guide the former are in a large measure applicable to the latter. The same overcrowding which is a cause of typhus is a source in hospital wards of pyæmia and erysipelas, in barracks and gaols of consumption, in certain endemic localities of contagious pneumonia, and probably of diphtheria.

The treatment of diseases of every kind has been largely, even if silently, influenced by the thought that the disease-breeding factors must also be, in individual cases, adverse influences to be carefully studied and kept in check, and in chronic cases especially a large part of the cure consists in the removal or modification of the cause.

2. *Self-healing Processes in Acute Diseases; Abuses of Venesection.* Closely allied with the change just mentioned is another which has begun to bear fruit largely only within my recollection. My own opinion is not perhaps of very much consequence; but I may state that at a very early stage of my career I became convinced of the great abuses of venesection, and I have not had any thing to cancel or recall in this respect. I am rather inclined if any thing to admit that the reaction of opinion against this and

other powerful therapeutic agents may have gone a little too far. But as to what may be called the Gregorian practice, probably differing even from Cullen's, and certainly from the genuine Hippocratic tradition, I think there can be but one opinion among my hearers. Forty years ago it was still a point open to question whether pneumonia and other acute inflammations could possibly be cured without blood letting. You all know what has come of the controversy famous in its day, on the particular subject of pneumonia between Dr. Bennett and Dr. Allison, and how completely the old traditional theory has been overthrown.

Here were given copious extracts from the teachings of James Gregory to the students of Edinburgh University in 1820, on blood letting in lung diseases. In these are seen the fanaticism of a powerful and vigorous mind, misled only by the fact that, under the influence of a traditional orthodoxy, he had never allowed himself to think or try other means. He advocated blood letting for pneumonia so extremely, that in one case a patient lost 96 ounces of blood in two and one-half days. Another 204 ounces in a week.

3. *Epidemic Fevers; Alcoholic Stimulation.*

—I am tempted at this point to allude to another instance of changed practice occurring within our own day, and applicable over a very wide area of disease.

In typhus fever as it occurred epidemically between 1819 and 1829, the idea first took root in some of the most prominent medical minds of that day, that alimentation not depletion, was the proper practice to be pursued in most of the endemic fevers. The idea leaned, however, more to the side of stimulants than food. The essential principle was that of supporting the strength and warding off the tendency to death from asthenia. With some this idea became merged into a process of high alcoholic stimulation. The practice associated with this theory was the subordination of all other nourishment to alcoholic liquors and especially brandy, given in huge doses continuously every half hour all day and night. So little indeed, did the previous habits, age or sex of the patient count that a nursemaid aged 18 had 48 ounces of brandy per diem at the height of her disease, and between 4 and 5 gallons in all. Another girl far gone in organic disease had several gallons of brandy in the course of a few weeks. Such excessive use of stimulation has been made the subject of learned inquiry and it is now regarded as an established position, that in typhus fever and

therefore in all fevers and diseases attended by febrile debility alcoholic stimulants are not the best form of alimentation, that their use is as a medicine within limits, and also within limits easily suggested by reason. Milk (which during the alcoholic fanaticism had been lost sight of), is in reality the food most easily digested and more conducive to success than any other.

I have thus endeavored to show you, by a few instances only in what manner and on what lines, the art of medicine has been advancing toward stability as I affirmed in the early part of this address. What has been doing in all these years has not been in vain. A vast army of earnest, unprejudiced, disciplined workers has been engaged upon all the unsolved problems connected with disease. Diagnosis and pathology have made immense strides during the whole of the present century. Operative surgery has achieved the most brilliant and unquestionable triumphs of any period in the long course of Medical history, and this in almost every department. Hygiene and sanitation, with their reflective influence on curative medicine, have advanced by leaps and bounds and even in strictly therapeutic methods, the changes though not so palpable or easily stated are all in the right direction.

A science of pharmacology, or of the uses and actions of medicines, is being built up on a foundation that was never possible before the present day, and which will render this, the least satisfactory department of the science of healing, far more secure in the future. Nor is the immense relief to human suffering by the use of anæsthetics, and even of anodynes and narcotics in greatly improved forms of administration, to be ignored even in the most brief allusion to the modern use of drugs.

All that removal of the old traditional dogmatisms has been merely a clearing of the ground by the fathers and grandfathers, and the fervid youth of the present generation is here permitted to sow the seeds and reap fruitful crops for humanity at large.

WM. MOORE, M. D., physician in ordinary to the Queen in Ireland, delivered the address before the Section of Medicine upon

Advance in Knowledge of Fevers.

After the customary thanks for the honor bestowed upon him he proceeded to state that it was mainly due to the application of the microscope, laryngoscope, thermometer, and such kindred appliances that the science of medicine had made such rapid strides

during the last quarter of a century. But we still want something more of the precision which holds in mathematical science, and this is especially true in clinical medicine.

To give a general review of the more prominent advances made in medicine as an exact science would here be out of place, hence he confined himself to one subject, the advances made in fevers, the direction of precision as regards their specific characters, their diagnosis, and prognosis. In his student days no branch of medicine was more unsatisfactory than the diagnosis, and treatment of fevers. Now symptoms are daily anticipated, and treatment carefully applied on sound therapeutical and pathological ground. With a glance we recognize the specific character of the fever, its duration, prominent symptoms, their clinical value, with the correlative conditions of pulse, and temperature, and ultimately the prognosis of the case. To whom is this exactitude in diagnosis mainly owing? Among others in this country, to the labors of the late Dr. A. Stewart, a distinguished member of this Association, and to one of our greatest living physicians, Sir William Jenner, whilst by Sir John Simon, and his co-laborers in the researches upon the causes of fever, results as to prevention have been obtained which have reduced the mortality to a minimum compared with fifty years ago.

Nothing leads to more exactitude in a knowledge of fevers than a true understanding of their duration, and the occurrence of salient symptoms in the various stages of a long or short fever. For instance, delirium occurring in scarlatina (a short fever) must be taken prognostically for what it is worth; whereas the same symptom at the same date in typhus fever would mean coma on the fourth day and fatality on the fifth. We must take another reading of delirium occurring later on in continued fevers, with the associated conditions of pulse and temperature, which in a thousand cases will hold with comparative precision. Whilst this is true in diagnosis and morbid anatomy, I fear prognosis and treatment have not advanced beyond the domain of probability.

While we are able to anticipate with comparative exactness the great structural changes demonstrated by pathology and morbid anatomy, and verified by the microscope, at the same time we must take into account the variety of types met with in epidemic diseases, and how far this may conduce to a want of exactness in scientific medicine. It is certain that our lack of knowledge of pathology led us in times gone by to the employment of unsuitable remedies, such as the active

purgatives in advanced stages of enteric fever; this has been rectified, yet we occasionally find a critical diagnosis, associated with a neglect of therapeutical means, which might be more successful in combating disease than the remedies of the pure scientist.

Time forbids my pursuing this wide and interesting subject further, and these crude remarks must only be regarded as imperfect pioneers for further reflection.

The address upon psychology was delivered by J. R. GASQUET, M. B., upon

The Physiological Aspect of Insanity.

The speaker thought that the abundance and importance of the bodily conditions that come before us do not distract from our minds the mental and moral phenomena of insanity. It is a question whether we do not look too much upon the physical side of the object of our study and too little upon the psychical. I have not the slightest wish to disturb the tacit agreement that questions of philosophy should be set aside by us and that our business is to study the concrete manifestations of mind. I am quite agreed with Lotze (*Logic*, chapter v.) that insanity is a disease of the bodily organization, and must be studied as such. But, "a moral sermon becomes intolerable if it goes on forever," and there does not seem much present risk of its being forgotten; while there is, on the contrary, danger of a reaction if we dwell too unduly upon the bodily side of our duty. The zig-zag path of human thought may at the next turn bring the physical aspect into undue prominence.

Our daily increasing recognition of the universal extent of heredity has somewhat lessened our attention to those factors of insanity which used to be called and still figure in the text books as moral causes—education, precept, example and all the manifold ways in which one mind can influence another. Of course, they all have a common physical basis in that tendency to imitation which is inherent in the nervous system as the highest form of reflex action, yet the connecting link between mind and mind is none the less purely psychical. What fields remain unexplored? Who has tried to unravel the tangled skein of family histories, and tried to estimate the share which the early training of neurotic parents have in strengthening the evil tendencies which they have already transmitted to their children? Happily, we seldom now have the opportunity of studying the effect of imitation in those epidemics of insanity which

have been so notable in the history of the world; but their records are still open to our study, and seem to justify my contention.

Jealousy, remorse, anxiety, grief, act only by and through the nervous system, but in their nature and origin are mental rather than cerebral. Passing from the causation to the symptoms we find psychology equally as deserving of more careful investigation than it receives at present. Many of the phenomena of insanity if tested by psychology turn out to be quite different from what they at first appear. It may even be suggested that the slowness with which psychiatry progresses may be largely due to our imperfect psychological analysis, which connects symptoms really dissimilar, and separates others which are only different in appearance. We may say roughly that the bodily condition supplies the direction which the insanity takes, while details by which every individual seeks to account for his altered feelings are derived from his past mental experience. Religious belief supplies delusions often of an endemic kind.

The way in which the systematic delusions of chronic insanity are gradually built up are curious and remarkable. For instance, we have all seen patients who start with the delusions of persecution, and gradually go on to construct the belief that they must be personages of exceptional rank or importance to be the victims of such persistent conspiracy and hatred. Or again: It is interesting to watch the growth of delusions in educated lunatics, by their continual attempts to meet real or fancied objections, so that the very reasoning which is employed to disabuse their minds leads to their increased confusion.

A question of greater delicacy and difficulty has been sometimes approached, but still awaits adequate investigation. It needs a very subtle analysis to discover whether all the mental faculties are alike liable to perversion, or whether any laws of thought or processes of mind remain standing amid the general ruin, and are always normal as long as they are manifested at all.

Neither will any one say that the several groups of symptoms which we include under the term "moral insanity" have been sufficiently studied. Many problems still await solution by the application of psychological analysis, though it has been carried much further in this than other directions, owing to the pressure of medico-legal requirements.

After all, the ultimate test of our medical knowledge is in its practical value. This fact excludes from my consideration the

services we might render psychology, were we trained psychologists. But it leads me to ask all the more urgently, is the psychological side of our speciality unduly neglected in treatment? As a proof that it is I need go no further than the term "moral treatment," which has been used so vaguely as to almost become ridiculous and fallen into disrepute. It is indeed true that the mental and moral influence of one mind upon another is never more wonderfully displayed than in the management and cure of the insane. To rouse the apathetic, to cheer the melancholy, to control the excited, to bring the self-centred lunatic face to face with the realities of life—these are noble powers indeed, which are being constantly exercised in asylums. But the tact which can do all this is personal and incommunicable, born of long practice, of frequent success, and still more frequent failure; it is the skill of the artist bringing forth harmony and order from the instrument on which he plays.

What a gain it would be if the beginner could start in some measure armed with the experience of past generations. That the thing is not impossible is shown by the success in a parallel profession of Mr. Sully's excellent Teachers' Manual of Psychology. It is from this point of view that such experiments as Dr. Savage in particular has recorded are of great interest; where lunatics are reasoned out of their delusions, and cured, so to speak, by psychology.

A profound conviction of the importance of my subject could alone have induced me to occupy your time to-day with what at first sight must appear mere fault-finding and criticism. I felt I could not do better than to enforce the old sentence, which says, *Ars artium regimen animarum*—"the art of arts is the government of souls."

The address upon Laryngology and Rhinology was delivered by W. MAC NEIL WHISTLER, M. D.

Gentlemen:—To tender a cordial welcome to all devolves upon me as the most pleasant of my duties to-day. To you who have so contributed to the history of our specialty by your researches and written records, any allusions from me to details of progress would be ill-timed and even presumptuous. For all these stages, since the time when the laryngoscope first gave insight to the hidden workings of the larynx in song, and lent some hope of aid to the physician, to the present day when in the fuller fruition of hope, laryngology has reached its present state of

undenied importance for the clearer understanding, and more rational and effectual treatment of disease, all these are known to you as household words. I may but say, as an incentive to all of us to further effort, that where so much has been done still more may be attained.

Much towards the furtherance of this end, I would suggest, might be gained by still more concerted action, and by readier opportunities for the discussion of these questions, which appeal more directly to us, than are afforded through the channel of the general medical societies only. By frequent inter-change of thought, mutual and great advantage must accrue to us as workers in a common cause. The wisdom that obtains from the multitude of counsels needs not to be insisted upon; while others engaged in special researches in the great work of medicine and surgery have proved their acceptance of this truth by establishing centres for the advancement of their art, laryngology and its associated specialty, rhinology have no such representations in England. Contrasted with this seemingly strange defect, the Laryngological Association of America is a bright example of the benefits of collective investigation which has even in the few years of its existence, given rich results, until the records of its annual transactions have become an invaluable addition to our literature. I would, gentlemen, express the hope that some proposition for the founding of an association for this object in Great Britain may yet be brought forward, and steps taken for its accomplishment.

Some may argue the asserted need is in no way real, in view of the required opportunity being supplied here in this subsection of the British Medical Association. I will plead second to no one in my sense of gratification at the establishment of this subsection, but the time allotted here must be of necessity limited, and the intervals between the sessions too long for the purpose to which I have alluded. In the true sense of a subdivision of that science which is our common interest, we may here still most fitly consider those themes which have a direct and practical bearing upon the questions which engage the attention of those whose sphere in medicines is less restricted than our own, though the detailed consideration of more abstract questions in our own specialty may more properly belong to the debate of a special society.

In, however, thus generalizing, and applying the result of our researches here, we, on the one hand, may be saved from what might

tend to too narrowed views, while on the other hand we link our special department more closely to the whole.

If in the expression of these thoughts I have seemed to you to tread too boldly upon what is possibly delicate ground, I pray you to ascribe such boldness to zeal, and not to any desire to be the critic of the past, or rush into the breach as an adviser for the future. I have but ventured to express an earnest wish. However sincere my expressions may be, it is my duty to curb these encroachments on that serious work which is the purpose of our meeting to-day. Let me not then further transgress upon our time, for you are not here to listen to a discourse from me, but I to hear and heed your words.

FOREIGN CORRESPONDENCE.

Letter from Berlin.

BERLIN, Aug. 4, 1887.

The summer months are not generally supposed to be favorable for a gynecological quest in any country, and here in Germany the holidays in the Universities are supposed also to cut off all work by the professors. I have, however, not found this to be the case; although in south Germany the heat compels a cessation for a few weeks in July or August, here in the north many continue to work as usual until late in August. I am at present visiting Professor (Geheimrath) Olshausen, and Dr. A. Martin daily, witnessing operations, and conversing upon gynecological topics.

Prof. Olshausen has not been long in his present position, having been called from Halle to take charge of the University Clinic and hospital for the diseases of women, to fill the place of Carl Schroeder, lately lamented.

I was vividly impressed with the sad loss we have all experienced, in common with all womankind, in attending a hysterectomy in the beautiful Frauenklinik this morning, in the same room in which I had been so kindly received by Prof. Schroeder a year ago.

Schroeder's personality is so vividly stamped upon all scientific German work to-day, that the image will long preserve its identity, and though dead, yet will the great man continue to speak to many generations of doctors.

Of the sad circumstances of his death I have been able to learn something more exact than the meagre views which reached us across the Atlantic.

His last appearance in the Berlin Gynecological and Obstetrical Society was on January the 14th, when he exhibited a pregnant uterus removed for myomata.

A week later he showed the signs of the illness which carried him to his grave. This illness began very suddenly, and exhibited so many changes that at the time he was called to attend the Princess Wilhelm in confinement, although unable to go himself, was able to speak in the clearest manner with Dr. Hoffmeier upon everything connected with the subject. He became suddenly worse immediately afterwards, and died on February 7th, at 3.30 in the afternoon.

The immediate occasion of his death was made only too clear, but the ultimate cause lies wholly wrapped in obscurity, in spite of the careful post mortem examination made by his friend, Prof. Rudolph Virchow. An old encapsulated abscess of the posterior part of the right lobe of the brain had broken into the right ventricle, and caused there a profuse acute suppuration, and finally a basilar meningitis. The right thalamus opt. was so pressed upon by this abscess that it was flattened down and deeply indented.

Also between the base and root of the right lung lay a remarkable body the size of a small nut, of fibro-cartilaginous consistency, containing a pus-lined cavity. This very remarkable body communicated with the oesophagus by a narrow canal. In a part of this mass were also found some very curious pigmented foci of cholesterin, such as Prof. Virchow had never before seen under similar circumstances. The lungs were perfectly healthy and a suspicion even of tubercle absolutely to be excluded. There were marked traces of old endocarditis. Such was the mysterious condition discovered, and no one seems to have been able to interpret it. Schroeder was a man of great power and personal magnetism, and such was the impression he made upon me in the frequent meetings last summer, that, since the news of his illness and sad death, all the facts I could glean have been constantly and vividly before me; and I may be pardoned if I venture apologetically to offer an interpretation of the fact which has suggested itself to me, and seems at least to bear an air of plausibility.

A pneumonia from which he suffered about five years ago was, I believe, *septic*; thence originated the disease of the heart, and the peculiar body at the root of the lung may be the remainder of an infected gland which discharged through the oesophagus and contracted.

The heart disease gave rise to an embolus in the posterior lobe of the right brain, where the absence of defined centres motor or sensory, account also for the absence of any prominent symptoms, until the abscess attained sufficient size to press on the thalamus, and thus mediately to disturb the optic centre, as indicated by twitching of the eye, by which he had latterly been annoyed. During the past year he had frequently complained also of unusual tired feelings. The rupture of the abscess, and the symptoms following are now only too patent (causally). The elevation of temperature was but slight at any time. Thus died one of the world's greatest men, a literal sacrifice to this work, the cause of suffering women.

Wonderful too in view of his disability, is the vast amount of work he was able to force out of his tired mental and bodily machine during the year preceding his death, a work crowned by the great obstetrical research on "the uterus in pregnancy and in labor," containing his great studies on the "contraction ring," which will I believe prove to be his most valuable contribution to scientific and practical obstetrics.

Did not time and space fail, I could find no pleasanter task than to trace the history of his life, from his student days in Wurzburg, to his call to Bonn, as assistant to Gustav Veit, where he first dedicated himself to that course followed with such brilliant results, through twenty-three years of his life; and then his removal to Erlangen, and finally to Berlin, where he built the great Frauenklinik. It would be of interest to his many admirers to hold up a picture of gynecology and obstetrics as they were when Schroeder entered upon the field, and as they stood comparatively, when he left, and to point out the strong mark of his hand seen in all fields of the work.

Such was the comprehensive character of his activity that a history of his work would be a fair picture of our advanced gynecological and obstetrical science of to-day. No unworthy jealousy will be roused when I say in concluding, that no living man can in all respects fill his place; and as the months roll on and we look back perspective seems to have reversed its rules, and we feel stirred to exclaim "there were giants in those days."

HOWARD A. KELLY.

—All the conductors on the Maine Central Railroad have been provided by the management of the road, with cases containing all the remedies to be used in cases of accident.

EDITORIAL DEPARTMENT.

PERISCOPE.

A Case of Extra Uterine Pregnancy.—The Fœtus Retained for Five Years and then Expelled through the Rectum.

Bubendorf reports the following case: At the second month of pregnancy the decidua was expelled from the uterus. At the fifth month the patient thought she felt the movements of the child. At the normal end of pregnancy a great quantity of fluid escaped from the vagina. This discharge continued some days without the appearance of the child. After a month, menstruation again returned regularly. A tumor was made out in the left side of the pelvis, but the patient suffered no pain. Five years later, without recognizable cause, foetal bones were evacuated from the rectum. The author thinks the pregnancy was tubo-abdominal and that the fluid escaped from the tube into the uterus and thence out. The fœtus at the end of pregnancy had died, but could not take the same way as the fluid, and so remained in the abdominal cavity until expelled per rectum. The mother nearly died at the time the bones were expelled.—*Centrallblatt f. d. med. Wissensch.*, July 9, 1887.

A Hitherto Unrecognized Body in Pathological Urine

Thormählen writes as follows in *Virchow's Arch.*, Bd. 108, S. 317: In a woman 36 years old, who was suffering from multiple, possibly secondary malignant tumors of the liver and spleen, there was observed in the urine a different course of the reaction with nitro-prusside of soda and caustic soda. That is to say, the primary red coloration called forth by these re-agents after acidulation with acetic acid was not distinct, and also not purple, which would indicate acetone, but an immediate gorgeous blue. Addition of alkalis changed the blue color into red, and then by acidulation with acetic acid the fluid again became blue. Respecting the behavior of the doubtful substance under re-agents, the following could be established: It is non-volatile, is easily decomposed by mineral acids, difficultly decomposable by organic acids, strongly resistant to alkalis, not precipitable with neutral acetate of lead, but on the contrary completely precipitated by solution of the subacetate of lead and ammonia, and out of this precipitate it can

be recovered by carbonic acid as well as by carbonate of sodium. Transferred from heated urine into hot alcohol, it is pretty completely precipitable out of this solution by an equal volume of ether, but on the contrary is insoluble in chloroform, rhigolen, benzol, bisulphide of carbon. This substance is normally present in the urine of horses and cats, and can be obtained in purer form from horses' urine by precipitation with acetate of lead, then acetate of lead plus ammonia, as well as by the method of Baumann and Brieger, though it is still not completely isolated.—*Centrallblatt f. d. med. Wissensch.*, July 16, 1887.

The Medical Treatment of Fissures in Ano by Cocaine.

M. MENDEL commences by cauterizing the affected surface with nitrate of silver after first applying a five per cent. solution of cocaine. He then orders the patient to apply, especially after defecation, the following ointment:

R	Acidi boracici.....gr. xxx
	Cocain. hydrochlor.....gr. xv
	Lanolin.....5 v
M.	

In the intervals of defecation he applies to the wound lint coated with this ointment, and prevents constipation by using saline purgatives. Moreover, he cleanses the surface of the fissure several times a day with three per cent. boric acid water. In this way Mendel obtained recovery in from one to two weeks.—*Le Concours Médical*, July 23, 1887.

Two Cases of Gonorrheal Endocarditis.

Among the relatively few recorded cases of endocarditis arising in a causal connection with gonorrhœa, an affection of the joint pretty constantly forms the connecting link between the urinary passages and the heart. The author, however, now publishes the histories of two male patients who experienced an attack of endocarditis in respectively three and four weeks after the beginning of gonorrhœa, without the previous occurrence of an affection of the joint. In one of these cases cure resulted, while the other led to insufficiency of the valve.—VON DEN VELDEN. *Centrallblatt f. d. med. Wissensch.*, July 23, 1887.

The Treatment of Acute Miliary Tuberculosis.

Lépine recommends iodine as the best remedy. Its employment in substance is obsolete, and as Binz teaches that the iodide in contact with living protoplasm and carbonic acid sets free iodine, the employment of preparations of iodine are to be preferred; especially as by them more iodine can be introduced into the system than by using pure iodine.—*Allgemeine med. Central-Zeitung*, June 29, 1887.

The Treatment of Dysentery.

During a service of thirty-five years in the British army in India, Mac Dowell had valuable experience with dysentery and its treatment, and declares that its horrors are vanishing since the following treatment has been employed: 1. An adult takes a dose of at least twenty to twenty-five grains of ipecacuanha. 2. The stomach is prepared to receive this dose by the patient's taking an hour beforehand, twenty drops of tincture of opium, and having a mustard plaster put over his stomach. The ipecacuanha is given in the form of large pills, taken in the evening before going to bed, never in the morning or in the course of the day. Subsequently nothing ought to be drank. This treatment is continued every evening, and in this way by the third morning blood, mucus, and pain have generally disappeared. During the day bismuth is allowable.

Small doses of ipecac are only harmful: they were used for two hundred years in India without removing the mortality.—*Allgemeine med. Central-Zeitung*, June 29, 1887.

A Case of Hæmatophobia.

In the Biological Society of Paris at its meeting on June 18, 1887, Féré introduced the subject of hæmatophobia. Many persons could not see blood without being seized with different kinds of attacks, such as syncope, hysterical attacks, etc. Some were only affected by the sight of their own blood; in some a handkerchief spotted with blood was sufficient, in others a strong stream of blood was necessary to call forth the attack. Féré treated a woman forty years old who suffered from hysteria and hæmatophobia. As he was examining her one day he brushed accidentally against her elbow. The patient immediately fainted. She subsequently informed him that during an attack of pneumonia some years before, she had

been bled from both arms; and since then she always lost consciousness whenever any one touched the spot on her arm.

Laborde places this phenomenon in the same category as the epileptic attacks which are induced by a scar. He himself had an old scar which formerly could not be pressed without his fainting. Brown-Séquard remarked that the motility of the reflex excitability is extraordinarily different and diverse in each individual.—*Deutsche Medizinische Zeitung*, August 8, 1887.

Treatment of Locomotor Ataxia with Rarefied Air.

Dr. H. M. Lyman gives the following summary of his opinions upon the treatment of locomotor ataxia:

1. That progressive locomotor ataxia cannot be cured by dry cupping.
2. That the painful sensations which accompany the evolution of the disease may sometimes be relieved by this method of treatment.
3. That the principal advantage resulting from the use of Junod's cupping apparatus consists in the improved nutrition of the muscles of the limbs which are subjected to its action.
4. That the delay of muscular atrophy thus procured is due to the local action of rarefied air upon all the structures of the affected parts and is limited to the tissues which are actually inclosed within the exhausted receiver.
5. That the improvement of nutrition is, therefore, principally accomplished by direct action, rather than by reflex influences exerted through the spinal cord.
6. That in the use of rarefied air we employ an agent which is competent to fill a subordinate and limited, yet often serviceable position in the treatment of cases that are characterized by a tendency to muscular degeneration.

This, probably, is also true in other diseases besides progressive locomotor ataxia.—*The Journal of Mental and Nervous Diseases*, July, 1887.

The Treatment of Insect Bites.

Dr. Bernbeck recommends the following formulæ:

- | | | |
|----|------------------------------------|------------|
| R | Collodii..... | parts 19 |
| | Acid salicyl..... | " 1 |
| M. | Sig. To be painted on as directed. | |
| Or | | |
| R | Collodii..... | parts 1000 |
| | Hydrarg bi-chlor. cor..... | " 1 |
| M. | Use as above. | |

These solutions cause the pain to diminish, and only in rare cases does swelling of surrounding painful parts occur.

The *Lancet* has recently recommended a weak solution of carbolic acid as a prophylactic.—*Allgemeine med. Central-Zeitung*, July 13, 1887.

Report of a Case of Extra-Uterine Pregnancy, the Fœtus Being Retained for Thirty Years and Becoming a Lithopædion.

Dr. W. H. Fales records the following interesting particulars:

In giving the history of this case, I hoped to quote from the records of the physician who attended Mrs. A. during her illness, and who, as I understand, took extensive notes, but I am unable to do so, owing to his death a few years since, and the subsequent destruction of his records.

I am fortunate, though, in that such information as I have comes from a twin sister, who is still a remarkably vigorous woman, both mentally and physically, and whose statements, so far as they go, are undoubtedly correct.

Mrs. A. was married September 24, 1844. Never had any miscarriages. She was delivered of a perfectly healthy child January 29, 1848.

Early in January, 1856, she became, as events proved, pregnant again, though her condition at the time was merely surmised, as menstruation continued to be present and in fact existed, with more or less regularity, throughout her entire pregnancy.

It was not until the middle of May that the attending physician made a positive diagnosis of pregnancy, basing his opinion on foetal movements which became manifest at that time.

Early in March of the same year while visiting friends, she fainted, vomited and complained of considerable epigastric pain. There was no flowing at this time. The following day she rode home, a distance of four miles.

Directly after this, she had three so-called inflammatory fevers characterized by abdominal pain, excessive tympanites and uncontrollable nausea and vomiting. During one of these attacks an abscess formed just above the pubes, which opened but did not discharge much.

Counting from the middle of May, when foetal movements began, October 1st would be the probable date of her confinement. About that time the physician was summoned, not on account of her labor pains, as

she *never* had these, but for excessive and painful movements of the child. These were always very marked, and caused her the utmost inconvenience. As she expressed it, she felt more life with this child in two hours than during her entire previous pregnancy. October 13th, the physician was again called, for the same reason. At this time "something was rubbed on the abdomen," after which the movements grew less and less, and finally ceased. For the next ten years she was an invalid, though nothing very explicit could be obtained as to her condition. She was generally miserable and had a number of attacks of abdominal pain, sometimes accompanied by icterus.

During this period the tumor very gradually decreased in size, finally remaining stationary and causing no trouble except a feeling of weight when standing or walking too long.

Her subsequent health was good until about two years ago, when a malignant growth attacked her larynx, which eventuated in her death December 24, 1886.

The autopsy was performed September 26th, Drs. Bill and Metcalf assisting.

The body was very much emaciated. The tumor was apparently situated about in the median line, but on palpation was found to extend downwards and to the left, the contained foetus occupying a sacrum-left-anterior position, but entirely out of the pelvic cavity, the base of the skull being on a level with the umbilicus. On making the incision the tumor was found to be adherent to the abdominal wall, and it seemed as though it would soon have made its way through, either from pressure or ulceration, so thinned had the structures become at the point of its adherence.

It was almost lying loose in the abdominal cavity, the only points of attachment being the one just referred to, the pedicle, and some small adhesions to the intestines.

The intestines were ranged round the tumor—none in front of it—and were one mass of adhesions, forming with the abdominal walls the sac, as it were, containing the tumor.

The pedicle passed directly downwards, enclosing the uterus and then fading out gradually into the peritoneum. Nothing that would answer for a placenta, or the remains of one could be found.

With the tumor I extracted the fundus, Fallopian tubes and ovaries, which furnished no points of interest. Any further examination was denied. The autopsy suggested an extra-uterine pregnancy of the abdominal

variety, but the history points rather to a ruptured tubal becoming an abdominal.

To epitomize the various dates:

Mrs. A. was married in 1844; first child four years later; second pregnancy eight years later; probable rupture of tube and subsequent attack of peritonitis at third month; death of fœtus at ninth month; death of Mrs. A. from cancer of the larynx thirty years later, the fœtus having become converted into a lithopædion.—*Boston Med. and Surg. Journal*, August 11, 1887.

Injectons of Eucalyptol in Pulmonary Tuberculosis.

In the French Academy of Medicine, Ball reported upon the results of this method of treatment which he had employed for a year at the instance of Roussel, of Geneva, in the Laennec hospital. Of twenty-one persons, six had died, ten were improved, and five remained under treatment. According to Ball, the medicine acts especially upon the septic material of the tuberculosis. Under its influence the night sweats and diarrhœa cease, the expectoration and the fever diminish, and the bacilli vanish from the sputum. On the contrary, Dujardin-Beaumetz, who had instituted similar experiments, obtained different results. According to him, the eucalyptol acts by directly lessening the expectoration, without exercising an influence upon the bacilli. In some patients the oppression increased as the expectoration diminished. Guiffart, who instituted experiments in the Hotel Dieu, could very quickly by these methods of treatment obtain, in three patients out of five, a great diminution of the dyspnœa and sleeplessness. A diminution of the expectoration could not be observed in the chronic cases, possibly because the treatment was of so short duration. At all events, as Guiffart declares, this method of treatment obtains diminution, especially of the dyspnœa.—*GUIFFART. Deutsche Medizinal-Zeitung*, August 4, 1887.

Curable Hypertrophic Cervical Pachymeningitis.

The author has collected together the cases of cervical hypertrophic pachymeningitis published during the last ten years, and to these he has added two observations of his own, and discusses the symptoms and course of the disease. Nearly all the cases were referred to cold as a cause. The picture of the disease was as first described by Charcot and Joffroy. Very frequently trophic disturbances show themselves in the skin and the

nails of the upper extremity; in two cases there was hiccup in addition to the customary symptoms of the disease, and in one an increased secretion of urine was present. With reference to the sexual functions it is to be noted that temporary impotence alternates with increased sexual impulse. The prognosis of cervical hypertrophic pachymeningitis is not unfavorable; in most cases recovery occurs and generally after the persistence of the disease for two to three years. As to treatment, the author recommends warm baths, the hot iron and sodium salicylate.—*HIRTZ. Centrallblatt f. d. med. Wissenschaft.*, July 23, 1887.

Silver Absorption in Plate-Workers.

It is not generally known that the skin of workmen who have to manipulate silver is liable to become impregnated with the metal. Observations made on 800 silver-workers in Berlin have shown that all of them had the characteristic patches of coloration. These patches are round or oval in shape, varying in size from a millet seed to a broad bean. As a rule they are not raised; they are anæsthetic, and occur principally on the dorsum of the left hand. Only workers in silver are thus affected, and not those who manipulate gold or copper. The absorption of the metal seems to have no effect on the general health. Microscopical examination shows that the patches are caused by the deposit of metallic silver in the tissues, and they are soluble in nitric acid and cyanide of potassium. It was noticed that the men affected were invariably those who had some ulceration or abrasion of the hands through which the metal was absorbed. The nature and shape of the metallic deposit warrants the supposition that the metal enters in a soluble form, and is then precipitated. Curiously enough, three workmen who were being treated for syphilis with mercury developed a number of fresh stains in a comparatively short space of time.—*Brit. Med. Journal*, August 6, 1887.

—Discussing the subject of the doctor's income, Dr. Paget Thurston says, that the trouble is not in want of patients, but in the low rates of fees; for Dr. Thurston says that in England ten per cent. of patients pay five shillings (\$1.25), ten per cent. pay 60 cents to \$1.25, while eighty per cent. pay such fees as no doctor or educated gentleman can possibly live on, the average for union, club, and dispensary patients being ten to fifteen cents.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT LITERATURE.

—The first annual report of the Visiting Nurse Society has come to hand. We would like to see this society enlarge its function so as to provide nurses to stay with the sick when this is necessary; but even visiting nurses are much better than none at all, and the organizers of the society have furnished a charity that merits more commendation than can be accorded many dispensaries.

—Henry Carvill Lewis's account of "The Alleged Pyschical Phenomena of Spiritualism," is a very interesting description of two seances with Eglinton. As might be expected from the high scientific attainments of the writer, his summary of the results of his visits to Eglinton are calm and dispassionate. The original paper will be found in the proceedings of the Society of Psychical Research, part XI, May 1887. Those who are interested in spiritualistic phenomena, will do well to read this paper in conjunction with the recent report of the Seybert Commission.

—"The Results of Vaccination and the Inequity and Injustice of its Enforcement," is the title of a paper by Wm. Tebb, President of the London Society for the Abolition of Compulsary Vaccination. It is never wise to underrate the dangers that may be incurred by vaccination, but when one reads the printed statement that such "diseases" as blindness, boils, bullae, cancer, gangrenous, inflammation, meningitis, phagedenic action, rickets, scald head, pyrexia, etc., etc., are due to vaccination *per se*, he must be peculiarly credulous if he believes it. The statement that such morbid conditions arise is credited to medical witnesses, but it is well known that some doctors see many strange things. We are still disposed to think that when bad effects seem to follow vaccination, they are due to constitutional disease, which may be latent until evoked by vaccination, to improper virus, or to some combination of the latter with external conditions.

—Dr. A. G. Sinclair, of Memphis, Tenn., in his little paper on "Iritis," read before the Medical Society of Tennessee, in April last, calls particular attention to a point general practitioners will do well to remember, namely, pericorneal congestion as indicating disturbance of intra-ocular circulation. The painful initial symptoms of iritis are well contrasted with neuralgia.

—Dr. Otis, whose name is a familiar one in genito-urinary surgery, calls attention in his paper "On Some Important Points in the Treatment of Deep Urethral Strictures," to the importance of first localizing a stricture before treatment is directed to curing it. He endorses Sir Henry Thompson's dictum, "If you cut at all, cut all." The liability of a stricture anterior to the membranous portion of the urethra to produce a tight spasmodic stricture behind it, should not be forgotten. The author asserts that he has known the passage of the flexible bougie or sound, when there existed a stricture of large calibre in the penile portion, to be followed by severe inflammation in many instances, and even abscess, sometimes of the prostate, sometimes of the head and even body of the testicle.

Items.

A case has recently been decided in one of the county courts of England in which a barber was held liable for damages for having infected a customer's face with *sycosis menti* through the use of an improperly cleansed razor.—*Boston Med. and Surg. Journal*, Aug. 18, 1887.

—An ink is prepared by Oscar J. Lache (*Am. Journ. Pharm.*) from sumach leaves by adding to one pint of the decoction from one ounce of the leaves, ninety grains of iron sulphate and sixty grains gum Arabic. The ink at first prepared has a brownish color which disappears in a few days, and after standing two weeks it can scarcely be distinguished from nut-gall ink.

—Susie.—"Oh, mamma, I'll never disobey you again."

Mamma.—"Why, Susie, what have you done?"

Susie.—"Well, I drank my milk at lunch and then ate—a pickle, and the milk said to the pickle, 'Get out,' and the pickle said, 'I won't,' and the're having an awful time!"

—Here are some queer London signs and advertisements: Sick dogs medically attended by the week or month. Birds to board. Ladies' and gentlemen's feet professionally treated by the job or season. Round-shouldered persons made straight. Babies or children hired or exchanged. False noses as good as new and warranted to fit. Black eyes painted very neatly.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium,	6.00
Physician's Daily Pocket Record,	1.50
Reporter and Pocket Record,	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,000 copies.

SPECIAL NOTICE TO SUBSCRIBERS.

Subscribers to the MEDICAL AND SURGICAL REPORTER, who have remitted payments to the former editor, and who do not find upon the wrapper of their journal a correct statement of the time up to which they have paid, are requested to notify the present publishers as soon as convenient.

IN MEMORIAM.

Nathaniel Archer Randolph, M. D.

On Sunday, August 21st, Dr. Randolph lost his life by drowning in the sea at Longport, on the New Jersey coast.

Dr. Randolph had gone to this place to secure a few days rest from the arduous duties which he had been performing as one of the editors of THE MEDICAL AND SURGICAL REPORTER, since the time when it came under its present management. The zeal and fidelity and industry with which Dr. Randolph performed his duties can be appreciated only by those who were familiar with

his methods of work; but the results have been seen in the pages of The Reporter, and must have been recognized by its readers.

He was a man devoted to the best interests of the profession, was in harmony with the best men in it, and was filled with the desire to make The Reporter one of the best medical journals in the country. His death is a bitter loss to his co-editor, and is also a loss to all the readers of The Reporter. The very sense of that loss is an incentive to those whose labors and responsibilities are increased thereby. Those who survive must continue and perfect the work of those who fall by the way. This is the truest tribute of respect which can be paid to the memory of the fallen.

SANITARY PROGRESS IN MIDWIFERY.

When Dr. O. W. Holmes in 1843 wrote his famous essay upon "The Contagiousness of Puerperal Fever," the majority of the medical profession, who were in a position to speak and teach authoritatively, were of the contrary opinion. Since that date there has been a complete revolution in medical belief. So great has been this change that milk fever, which until recent years was regarded as a physiological pyrexia, has now been relegated to the domain of pathology as merely an evidence of septic infection. A physician engaged in family practice is now as careful to keep his hands clean before attending a case of confinement as in all times he has been to keep his reputation unspotted. With the advent of the antiseptic system of surgical treatment came a close inquiry into the mortality of the lying-in wards of our large hospitals. As a result of this a steady and persistent effort has been made by good men to render the environment of women during their confinement in the first place as aseptic as possible; and when any injury of the maternal structures has taken place, to treat the womb and the patient with rigid antiseptic precautions.

As these measures have been in force for several years, it is interesting to note the result at La Charité according to the statement of Budin (*Le Progrès Médical*, June 18, 1887). In thirteen hundred and forty-nine confinements occurring between the years 1883-6 inclusive, there was a total mortality of twenty-one in the hospital, or 1.55 per cent. The total mortality due to infection was nine, or .66 per cent.; of these nine, four received their infection in the hospital, making a percentage mortality due to infection received in the service of .29 per cent. This is an exceedingly gratifying result when it is remembered that all applicants are admitted, no matter whether they have advanced phthisis or incipient septicæmia or eclampsia. Quite a number of the deaths occurred shortly after admission, and from the nature of the cases was unavoidable. Budin also accurately describes the furniture and appointments of the lying-in rooms, and the rooms for pregnant women.

We cannot help thinking that they are inferior in aseptic efficiency to the maternity wards of our own city hospital, inasmuch as the latter are entirely separate and distinct buildings from the rest of the hospital, and with equal care and foresight ought to show better results than La Charité.

THE BACILLUS OF SCARLET FEVER.

In June last, Dr. Alexander Edington, wrote a paper in the *British Med. Journal* upon the various micro-organisms that had been isolated from the blood and desquamating epiderm of patients suffering from scarlet fever. He has been able to make cultivations of this bacillus scarlatinæ. The growth under the influence of heat is very rapid, but unless transfers of the seed material are made from the surface of the growth, cocci develop to such a degree and with such rapidity that in ten days no bacilli are found. In blood-serum the bacilli grow badly. On potatoes, however, a rapid and luxuriant growth is soon obtained. "At 64.5° F. one finds after twenty-four hours a thick citron-white pellicle with the central portion tending to a citron-yellow color; after forty-eight

hours this coloration will have been seen to spread outwards, while the central part has increased in color, passing from this color gradually to that of ochre, and still later assuming a color identical with that of bread crust, and after some days the whole potato will be covered with a growth of this kind. Coincident with the increase of color will be noticed a rinkling of this pellicle, until at last the whole surface of the growth presents a tessellated appearance, while the potato under it is found to be moist, almost semi fluid." Such a growth consists almost entirely of spores, whose capsules stain a faint blue, with a 2½ per cent. watery solution of methylene blue. These researches of Edington are important as bearing upon preventive medicine. If the epidermic scales which separate from the skin of a scarlatinal patient and are then carried by the air contain these bacilli, then we have on the one hand a scientific explanation of the value of inunctions of oil in this disease, a practice that has become routine with many able physicians; and on the other, a most cogent reason for complete isolation of scarlatinal patients. It has long been known that scarlet fever could be conveyed by these epidermic scales, and isolation of scarlatinal patients is not a recent practice, but it is interesting to notice how gradually, step by step scientific investigation confirms the methods of practice long since adopted as the wisest by careful clinical observation. As in every other branch of knowledge, art is followed and explained by science; and in medicine, for the diagnosis and cure of disease, we must ever look to observation and experience to lead the way.

THE TECHNIQUE OF TRACHEOTOMY AND INTUBATION OF THE LARYNX.

This is a reprint of a paper by Dr. C. G. Jennings, read before the Michigan State Medical Society, and justifies its title. It is a very clear and concise statement of how to perform these two operations, which, together with arrest of hemorrhage and hernia, every general practitioner of medicine should become familiar with.

NOTES AND COMMENTS.

THE MODERN TREATMENT OF COMMON DISEASES.

DYSPEPSIA (*continued*).

LOSS OF APPETITE.—When this exists there is generally more or less atony of the gastric mucous membrane, in which condition the vegetable bitters are useful:

- R** Pulv. cascarillæ..... $\mathfrak{z}$ j
 " rad. rhei.....gr. xv
 " columbæ..... $\mathfrak{z}$ ss

M. ft. pil No. L. Sig.— $\mathfrak{z}$ three times a day. (Ewald.)

Not infrequently an aromatic is happily combined with the bitter, inasmuch as it is more stimulating though also more evanescent in its action:

- R** Tinct. cinnam..... $\mathfrak{m}\mathfrak{x}$ xxxvj
 Pulv. rad. columbæ.....gr. cvijj
 M. Div. in pulv. No. xii. (Ewald.)

Sometimes it is best to guard against the irritant properties of bitter drugs. This may be done by combining a small quantity of morphia with the prescription. The following formula is also useful when loss of appetite is combined with a tendency to cramps:

- R** Morph. acetat.....gr. iss
 Tr. gentianæ
 Tr. columbæ
 Tr. quassia
 Tr. cort. querc..... $\mathfrak{a}\mathfrak{a}$ $\mathfrak{f}\mathfrak{z}$ vj

M. Sig.—Teaspoonful several times a day. (Graves.)

EXCESSIVE ACIDITY.—As stated in the previous number of the REPORTER, this may be relieved by acids before meals or alkalies after meals (Ringer). The following formulæ will be found of service:

- R** Potassii bicarb.....gr. xc
 Cort. aurantii.....gr. xlv

M. Div. in pulv. No. x. Take one powder in sweetened water three times a day.

- R** Sodii nitratis..... $\mathfrak{z}$ ij
 Bismuthi subnit.....gr. xv
 Gummatis arab..... $\mathfrak{z}$ ss
 Aq. destil..... $\mathfrak{f}\mathfrak{z}$ vij $\mathfrak{z}$ vij

M. Sig.—Teaspoonful every four hours. (Ewald.)

If constipation also exists, the following may be used:

- R** Inf. rad. rhei..... $\mathfrak{f}\mathfrak{z}$ iss
 In this cold dissolve:
 Sodii bicarb.....gr. cl
 Syr. aurantii cort..... $\mathfrak{f}\mathfrak{z}$ vj

M. Teaspoonful twice daily. (Ewald.)

Or:

- R** Calcii carb. præcip.....gr. cxxxv
 Magnesii carb.....gr. xc
 Sem. myristicæ pulv.....gr. vij
 Sacch. alb..... $\mathfrak{z}$ iv ss
 Gummatis arab.....gr. xlv
 Aq. destil.....q. s.

Fiant trochees No. xx. Part of one may be taken several times a day. (Ewald.)

Or:

- R** Inf. rad. rhei..... $\mathfrak{f}\mathfrak{z}$ iv— $\mathfrak{f}\mathfrak{z}$ vss
 Sodii bicarb.....gr. lxxv
 Ol. menth. pip..... $\mathfrak{m}\mathfrak{x}$ iv
 Syr. aurantii cort..... $\mathfrak{f}\mathfrak{z}$ vj

M. Sig.—Tablespoonful every two hours when there is gastric and intestinal catarrh. (Ewald.)

FLATULENCE.—When this is due to fermentation, creosote and carbolic acid are useful:

- R** Creosoti.....gr. iij
 Aq. flor. aurant..... $\mathfrak{f}\mathfrak{z}$ j— $\mathfrak{f}\mathfrak{z}$ vij
 Tr. ferri acetat. æth.
 Ætheris
 Syr. aurantii cort..... $\mathfrak{a}\mathfrak{a}$ $\mathfrak{f}\mathfrak{z}$ ss

M. Sig.—Teaspoonful every two hours. (Ewald.)

- R** Acid carbol.....gr. xv
 Pulv. rad. rhei.....gr. lxxv
 Mucil. gummatis arab.....q. s.

M. Div. in pil. no L. Sig.—One three times a day. (Ewald.)

When flatulence is the result of insufficient gastric juice:

- R** Acid hydrochlor..... $\mathfrak{m}\mathfrak{x}$ lxxv
 Aq. menth. pip..... $\mathfrak{f}\mathfrak{z}$ iss— $\mathfrak{f}\mathfrak{z}$ ss
 Syr. aurant. cort..... $\mathfrak{f}\mathfrak{z}$ vj

M. Sig.—One-half teaspoonful in water after each meal.

- R** Acid. Hydrochlor..... $\mathfrak{f}\mathfrak{z}$ v
 Aq. destil.
 Syr. zingib..... $\mathfrak{a}\mathfrak{a}$ $\mathfrak{f}\mathfrak{z}$ ss

M. Sig.—Ten drops in water after meals. (Ewald.)

Charcoal is often valuable in flatulence associated with acidity:

- R** Pulv. carb. lig..... $\mathfrak{z}$ vj
 Lig. quassia
 Magnesiae carb..... $\mathfrak{a}\mathfrak{a}$ $\mathfrak{z}$ j

M. Teaspoonful several times daily. (Ewald.)

- R** Pulv. carb. lig.
 Sodii bicarb.

Elæosacch. menth. pip..... $\mathfrak{a}\mathfrak{a}$ gr. viiss

M. Ft. pulv. Take $\frac{1}{2}$ one hour after every meal. (Ewald.)

- R** Pulv. carb. lig.....gr. vi
 Acid. salicyl.....gr. iss

M. Put in capsules No. x. Take one $\frac{1}{2}$ hour after meals. (Ewald.)

SLOWNESS OF DIGESTION.—In a large number of cases of dyspepsia, food after entering the stomach seems to the patient to lie there like a dead weight. Sometimes after remaining a while in the stomach it is regurgitated in a nearly unaltered condition; or in other cases digestion proceeds so slowly

that gases form, resulting in flatulence, eructations and colicky pains. It is in these cases that pepsin and, if the dyspepsia be intestinal, pancreatin, are of great value. A number of useful formulæ will be here appended:

R Pepsin, sacch. gr. lxxv
Strychninæ gr. i-13
Sacch. lactis. gr. cl
M. Div. in pulv. No. x. Sig.—No. i.

R Acid, hydrochlor. ℥ cl
Aqueæ menth. pip.
Aqueæ destil. āā f 3 j. f 3 ivss

M. Sig.—No. ii.

Dissolve one of the powders in a glass of water and place in it a teaspoonful of No. ii. To be taken $\frac{1}{4}$ hour after meals. (Ewald.)

R Pepsin. gr. xxx
Acid. salicyl. gr. viiiss
Glycerini. f 3 j f 3 ivss
Tinct. calami. ℥ cl
Sig.—Teaspoonful dose. (Ewald.)

R Pepsin. gr. cl
Pancreatin. gr. cxiv
Sacch. lactis. 3 j 3 ivss
Ext. malti. gr. lxxv
Acid. lacti. gr. xxxvij
Acid. hydrochlor. dil. ℥ cl
Glycerini. 3 v
Tragacanth. q. s.

M. Div. in ten pill masses (Lactopepsin). (Ewald.)

R Pepsin. gr. lxxv
Acid. hydrochlor. ℥ viiiss
Rub together exactly.
Ext. gentianæ. q. s.

M. Ft. pil. No. L.

One pill several times a day. (Ewald.)

R Pepsin. gr. xxxvij
Acid lactic. gr. iij
Amyli. gr. xl

M. Ft. pulv. No. v. To be taken an hour after meals when there is too little acid in the stomach. —(Corvisart.)

R Pepsini. gr. lxxv
Morph. hydrochlor. gr. i-6
Amyli. gr. xc

M. Div. in pulv. No. xv. In increased irritability of the gastric mucous membrane.—(Corvisart.)

The following formula is also useful though without pepsin, in the so-called atonic dyspepsias:

R Inf. rad. rhei. f 3 iv-f 3 vss
Elixir aurantii. ℥ lxxv
Syrupi. ℥ iv
Sp. æth. nit. ℥ viiiss

M. Sig.—Tablespoonful every half hour. (Ewald.)

A Case of Peritonitis from Injury.

A case of considerable medico-legal interest has recently been tried in the County Court of Skipton. A boy aged 13, who was attending the Grammar School, was squeezed by one of the masters against the desk at

which he was sitting. He believed it was done as a punishment; but another boy, who saw it, thought it was intended as a joke. The master in question denied all recollection of the occurrence. The boy said he was trying to stand up at the moment, so that his umbilical region was compressed against the ledge of the desk. He complained of being hurt at the time, and was obliged to go home and go to bed on account of the pain; and on the succeeding days he was so unwell that, on his return from school, he went to bed each day. A few days afterwards he was persuaded to play at football, but had to desist in less than a quarter of an hour, as he felt so ill. About the twelfth day after the injury Dr. Wylie was called in, and found that the boy had well-marked local peritonitis in the umbilical region, from which, after a good deal of suffering, he eventually recovered. In the end the jury found that the peritonitis had been due to the squeezing, but that the master had pushed up against him in joke, and not with intent to do him harm, and awarded the damages at £10. An attempt was made to show that the peritonitis must have been caused in some other way, as it was so long in making its appearance; and medical evidence was called to prove that acute peritonitis usually set in within a few hours after the receipt of the injury, but that the time at which it commences must depend upon the nature of the injury. Great violence, no doubt, may produce an exceedingly rapid acute peritonitis; but a lesser degree of violence would produce only a subacute peritonitis, and we should not expect it to make its appearance so soon. After all, there is no evidence to show in this case when the peritonitis did develop; and, judging from the nature of the injury, it seems most probable that its course was a very gradual one, and that it had been in existence for many days before the medical man was consulted.—*Brit. Med. Journal*, August 6, 1887.

The Ripley Birching Case.

The case of the child of seven who was alleged to have been so brutally beaten by order of the magistrate to which we alluded in our last issue, has excited a great deal of interest. Sir Walter Foster saw the child five days after the flogging, and found distinct traces of what he considered to have been a brutal flogging. He therefore, addressed a question to the Home Secretary in regard thereto; in reply to which the latter gave a very different version of the affair, based on information received from the police

authorities. He nevertheless assured his listeners that in future a "lighter rod would be used for very young children," meaning apparently children under seven. It is simply monstrous that children of such tender age should be subjected to corporal punishment at all, and we hope that the practice will soon be put a stop to.—*The Med. Press and Circular*, Aug. 3, 1887.

A Nutritive Enema.

Ewald gives the following prescription: Take two or three eggs and beat them up smoothly with a tablespoonful of cold water; next heat a half cup of a twenty per cent. solution of glucose with a pinch of starch, and add a wineglassful of red wine; then pour the solution of egg in slowly, taking care that the solution does not become warm enough to coagulate the albumen. Before injecting this enema, the lower bowel must be emptied by clysters.—*Deutsche Medizinal-Zeitung*, July 21, 1887.

Improved Hartshorn Liniment.

After alluding to the reasons why the Committee on Revision of the Pharmacopœia substituted cotton-seed oil for the olive oil formerly ordered, and the fact that cotton-seed oil does not saponify with water of ammonia, Prof. Joseph P. Remington gave some experiments, and then alluded to lard oil as being far the most satisfactory. If this (lard oil) be substituted for the cotton-seed oil in the present pharmacopœial proportions: Water of ammonia, 30 parts (or 5 fluid ounces); lard oil, 70 parts (or 11 fluid ounces), the result is entirely satisfactory. After standing some weeks, the resulting mixture has not changed its consistence, and partial saponification is evident.

Dental Anesthesia.

M. Georges Vian claims to have solved the problem of local anesthesia in dentistry. After numerous trials of solutions of different strengths, he has found that the soft parts about the maxillæ may be rendered completely insensible by the use of cocaine, associated with a two per cent. solution of carbolic acid. Five minutes before operating, M. Vian dissolves five centigrams (one grain) of hydrochlorate of cocaine in fifty centigrams (ten drops) of the solution, and injects it into the gums, half-way between the neck and the extremity of the root of the tooth. Half of the solution is injected on the palatine, and the remainder on the labial side, pressure being made by the finger, when the needle is withdrawn, to prevent the exit of the fluid. Anesthesia is perfect in three

minutes. The quantity of cocaine advised by M. Vian seems somewhat large, but it is said to have been so used in eighty-seven cases, without causing any unpleasant symptoms.

On the Influence of the Cortex upon the Dilatation of the Pupil.

Mislowsky finds that stimulation of different places in the cerebral cortex by weak currents produces dilatation of the pupil in dogs and cats. He was unable to find a spot from which he could obtain contraction of the pupil. Dilatation still occurred after section of the cervical sympathetic, extirpation of the upper cervical ganglion, and after the trigeminus was severed from the ganglion of Gasser and the spinal marrow at the height of the atlas. Stimulation fails after severance of the oculo motor or of the trigeminal nerve behind the Gasserian ganglion.—*Centrallblatt f. d. med. Wissensch.*, July 2, 1887.

Heroic Treatment of Incomplete Abortion.

Two papers in the March number of the *Jurnal Äküschersta Jenskikh Bolësnëi*, by Dr. Fisher and by Dr. Khazan, deal with the treatment of incomplete abortion by thoroughly scraping out the interior of the uterine cavity with a sharp spoon. Neither of these physicians has found it necessary to use an anæsthetic during the operation. Dr. Fisher places the patient on the back, Dr. Khazan on the back or left side. The most careful disinfection is carried out by both, Dr. Fisher using a double current catheter passed into the uterus, Dr. Khazan mopping out the cavity with sponges. The former practitioner does not find dilatation of the os necessary, while the latter uses, if required, Hegar's bougies or tents. After the uterine cavity has been scraped quite clean, it is again disinfected, Dr. Khazan going so far as to mop it out with a solution of perchloride of iron. The vagina is plugged, and ergot, or ergotine, administered. Dr. Khazan makes the patient lie on her face for the first two days.—*Brit. Med. Journ.*, August 13, 1887.

CORRESPONDENCE.

An Unusual Effect Following the Administration of Quinine.—Sectarianism in Medicine.—The Exception to the Rule.

EDITORS MED. AND SURG. REPORTER:

Within the past few weeks I attended a lady suffering from double tertian fever, supposed to have been brought about by a visit to Atlantic City; but of course we are not aware of that, as patients are often there for the purpose of overcoming any malarial tendency to which they may be subject. The patient under consideration took at one dose eight grains of quinine sulphate, and in the short space of half an hour the skin began to burn and itch, and caused her the greatest uneasiness. Two hours later I saw her, and at that time the skin looked like a piece of red flannel. In reply to my inquiry she said she had experienced two attacks previously, one after taking some kind of medicine three years ago; and she added, that when the doctor saw her he told her it was "sharlet roosh," and went out and got a broom and commenced sprinkling carbolic acid all over her and the room. The children were kept away from her, and the neighbors, alarmed at the report, would not come near her for days, and she just wouldn't have him any more.

Strange things happen to the doctor while visiting amongst his patients, and the above incident reminds me of one that occurred some time ago. An elderly lady, just recovering from an attack of pneumonia, and not very strong, was advised to add meat to her diet, but I was somewhat surprised at the positive manner in which she declaimed, and remarked jokingly to her daughter who was in the room, "Oh, I see, she is a vegetarian." "No, doctor," said she, "I am a Methodist to the backbone."

When studying grammar, I distinctly remember how efforts were made to imprint on my memory the statement that "exceptions strengthen rules," and reading Dr. Calkin's article in the last issue of the REPORTER reminds of the need of making exception to some of the positive rules he has laid down concerning "The Etiology and Treatment of Female Sterility." He says: "One fruitful cause of sterility is hypertrophy and hyperplasia of the uterine muscle, from cervical and perineal lesions." Again, "To insure fertility, *there must be a healthy endometrium with its corpuscular layer well developed.*" Now, these statements are not to be taken as if they were part and parcel

of the laws of the Medes and Persians, for not long since I had a patient under treatment whose troubles took in nearly the whole catalogue, with most terrible attacks of dysmenorrhea, and yet she conceived. The worst of it was that she blamed me for leading her to believe that she would not become pregnant. The only resource left for me was to repeat the old maxim, that "all signs fail in dry times."

JOHN AULDE, M. D.

Mysteriously Trephined.

EDITORS MED. AND SURG. REPORTER:

D. H., aged about 25 years, consulted me about three years ago in regard to a "sore spot" on his head, situated just above the temple. Over an area nearly the size of a silver half dollar, there was some swelling, induration and tenderness. He said the trouble had existed for a considerable time, though he could not tell exactly when it commenced, so trivial did the affair seem at first. I diagnosed it a bealing [suppuration] of some kind, but was in doubt as to its real nature. Ordered a poultice. Very little change in appearance during next few days. Found symptoms of diabetes, and upon examination of urine, found sugar in large quantities. I naturally assumed that the small bealing upon the head was simply an effort of nature to get rid of some impurities in the blood due to the diabetic condition.

Pus finally formed, which I drew off with a hypodermic syringe. When I got tired of *pumping*, I made an opening with a lance, pressed out the pus and tried to explore the cavity with a probe, but the last being very painful I did not make the examination very thorough. I kept him, of course, upon proper treatment for the diabetes. He never lost a day from his work and sometimes I would not see him for weeks at a time. At the end of six or seven months he came into my office. The abscess was still discharging. I now discovered what appeared to be loose bone. I enlarged the opening and removed a *single piece* about the size of a silver quarter, nearly round and the full thickness of the entire skull.

But for its serrated edges one might have thought that the ghostly hand of some departed surgeon had been beneath that scalp wielding the trephine. How was that skull fractured? Surely it had been fractured sometime, but when or by what agency I cannot determine. When at his work (railroad carpenter) he would occasionally get a hit on the head, but at no time can he remember of having received one sufficiently

severe to cause him to think of it an hour later. The head healed up in few days after the removal of the bone. It has given him no trouble since, and now he is *apparently* free from the diabetes.

Lewistown, Pa. WALTER H. PARCELS.

EDS. MED. AND SURG. REPORTER:

Sirs—I see considerable discussion in your valuable journal respecting the use of quinine in pneumonia. I have made liberal use of the drug in the above named disease for the last twenty years, and must say that I have in no wise been disappointed by the results. With your permission I will briefly relate the most remarkable case that I have met with.

Five years ago last March, I was called some fifteen miles from home to see a patient who, I was told, had been abandoned to die by his medical attendants. Found a large muscular man nineteen years old. Double croupous pneumonia, no normal respiration below the upper lobes, the lower lobes of left being silent, expectoration of dark rusty sputa—very profuse. Respiration 40. Pulse 130. Temperature 104° F. Lips, tongue, and nails blue. Delirious. The father of the patient said that he had had a cathartic followed by tartar emetic, and that they had been afraid to administer quinine on account of the high fever.

I put sixty grains of quinine in a cup and stirred it up with water. He swallowed it without noticing the taste. I then left a powder of forty grains more to be taken in four hours. As I could not attend him so far from home, I told them to send for their physician again, leaving a note for him. I heard nothing from him for two weeks, when his father came to my office to pay the bill, saying that his son was well, and that those "two doses had cured him." He has taken no other medicine and did not send for their doctor. He commenced to sweat soon after taking the first dose, the sweating continuing several days. It is my belief that recovery in that case was due to the large dose of quinine.

Muscatine, Iowa. A. ADY, M. D.

Homœopathy.

EDS. MED. AND SURG. REPORTER:

Sirs: Will you permit me the use of some of your valuable space in the endeavor to reply to the queries contained in the REPORTER of this date upon the homœopathy question? Having availed myself of opportunities favorable to an acquaintance with the methods of practitioners of the sect, and

having read extensively of the literature bearing upon the subject of the claims of homœopathy to recognition as a rational system of medicine, I think the views herein presented will fairly represent the sentiment and feeling of the regular profession upon the matter in question.

1. Medicine is not an exact science; and yet we now recognize many principles in pathology, diagnosis and therapeutics upon which reliance can be safely placed, and the correctness of which have oftentimes been amply and fully vindicated. A host of workers of many nationalities are laboriously engaged in sifting the true from the false and in wresting from nature secrets long hidden from the light. Have you ever observed that all the work is being performed within the *regular* profession? There is no ground we can occupy in common with vagarists or dogmatists. The domain of science should not be entered by one burdened and hampered by preconceived views. The spirit of scientific enquiry should be perfectly free. We should be ready to relinquish the view we entertain to-day should to-morrow's experience throw doubt upon its verity. A homœopath would be ever seeking for that which would fortify his peculiar tenet or theory, and would be content with nothing else; therefore we cannot work in his company.

2. That which is true in homœopathy is not new, and that which is new is not true. There are a few facts, particularly in therapeutics, upon which the homœopaths have pounced, and in which they impudently claim a proprietorship. As no important principles are involved we have done little to dispute the claim. If there be a "larger law" than any yet discovered, a co-operation with dogmatists in the seeking for it is not apt to hasten its disclosure. If you work out your problem by arithmetic and you discover that your neighbor who claims to have worked it out by algebra has not really done so at all, but has used more of your figures than of his own symbols, you are justified in calling him a fraud and a pretender, and in declaring yourself above further competition with him in the working out of problems. And this leads me to the assertion that homœopathy is a myth, and that it is found chiefly in lectures and in books, that in actual practice it is not to be found. The little pills, the potencies and the impotencies are used only in cases of no gravity, and where the "*vis medicatrix nature*" is alone sufficient. In serious cases the homœopath

resorts to the same doses as ourselves, being partial to the alkaloids, a large dose of which can be put in small compass and rendered almost tasteless. This cannot be called honest or honorable practice, and no fair minded person can find fault with a regularly educated physician for refusing to recognize or affiliate with one guilty of such conduct.

3. If a homœopath habitually resorts to the remedies and doses he affects to discard in toto, he is guilty of a sort of piracy, for which, most unfortunately there is no penalty, but the contempt of all honest men. If you doubt that this is done, inquire of the dealers in drugs and medicines as to the potency of the many of the pellets and tinctures purchased by so-called homœopaths. A regular physician is bound to no law of dosage. He may, if he will, use an infinitesimal dose and there is nobody to call him to account; but to do so he would be open to the charge of folly, and further than that, would, morally, be guilty of malpractice.

4. This subject has been fully inquired into and has long ago been settled to the satisfaction of science. Homœopathy has no recognition in scientific circles here or abroad. Nowhere in the world can a homœopath serve in the position of naval or army surgeon. Homœopathy is a myth. It serves to catch patients. It is, in the present order of society in the United States, a pretty good trademark. In spite of appearances to the contrary, it is on the decline. There is no excuse for its existence. All the great discoveries of the century, so far as relates to the laws of disease and the best mode of treatment, have emanated from the *regular* profession. Our only policy in dealing with homœopathy and other "pathies," should be one of no compromise. There can be no fellowship between light and darkness. I would invite your lay correspondent to avail himself of the literature of the subject. He will find "Hahnemann's Organon" a good work to begin with. Then peruse some of the more modern works on homœopathy. Like enough they will be found to contain their own refutation; if not, read Sir James G. Simpson's "Homeopathy, its tenets and tendencies," Oliver Wendell Holmes' work on the subject, and for something more recent, Dr. Palmer's masterly article in the *North American Review*, for July, 1882, if I recollect aright. The American people are proverbially fond of being humbugged and need some plain talking to upon this subject of homœopathy.

JAMES J. THOMAS, M. D.
Youngstown, O., Aug. 13, 1887.

NEWS AND MISCELLANY.

Preservation of Leeches.

J. T. writes as follows in the *Chemist and Druggist*, August 6, 1887:

As this subject is being discussed in your valuable journal, I give my method of keeping leeches, which I find answers well, and is less trouble than that of some of your correspondents. I never give leeches any meat or worms; they are kept in an earthenware vase, which has been in use about fifty years, with glass cover and perforated zinc rim; in the bottom are a few pebbles, and part of an earthenware drainer, through the holes of which the leeches crawl when they require a little help to cast their skin. The ordinary tap-water (off the limestone) with which they are supplied is changed three times a week in summer, and once or twice a week in winter. Loss or complaints are very rare, sometimes not once in six months. I always dry leeches before selling, for two reasons: (1) because they bite more readily, and (2) because the glue of the box is often moistened when they are sent a distance. I should think the weeds, earth, &c., which some advocate, would make it rather difficult to find half a dozen or so.

An Insect-Fight.

C. G. Rockwood, Jr., writes as follows in *Science*, August 19, 1887:

An observation quoted by Professor Morse in his address before the American Association last night is so exactly confirmed by a recent observation of my own, that it seems worth while to put it on record.

While sitting in a hammock, slung between two large maple-trees on the lawn, I heard a loud buzzing and fall of something behind me, and, looking around, I saw on the grass a locust (cicada) in the grasp of a large insect, evidently of the wasp family, but which I am not sufficiently well posted in entomology to name. It had brown wings, and large abdomen colored black or dark brown with white spots. The whole length of the insect was about thirty-five or forty millimetres. When first seen, the struggling locust was on its back; the wasp extended above it head to head, and industriously plying its sting between the abdominal wings of the locust. The locust quickly became quiet, and then the wasp, maintaining its former position, which it did not at any time abandon,

grasped the head of the locust by the middle pair of legs, and, using the other four legs for locomotion, started to drag it through the short grass toward one of the trees. There was no hesitation or uncertainty, but the wasp started at once in a straight line for the foot of the tree. On reaching the tree, the wasp began without pause to carry its burden up the trunk, using its four legs for walking, as before, and assisting itself to sustain the weight of the locust by putting its wings in operation. In this way, with a few brief pauses as if to rest and get better hold, in one of which it hung for a moment apparently by one leg, the locust was carried up among the branches of the maple, some twenty feet or so, where it became difficult for me to follow its motions. After reaching such a height, the wasp flew off in a straight line through the branches, and went out of sight. I think it carried the locust with it, but the height was so great that I could not be positive. At any rate, the locust did not fall to the ground, although, as the wasp's flight started from a crotch in a limb, it is possible that the locust was left in a crotch. The whole incident showed a perfect understanding, on the part of the wasp, of what he proposed to do, and the carrying out of a preconceived plan of procedure without any stopping to think what he would do next. The only pauses were in going up the trunk of the tree.

Breathing Pure Oxygen.

According to the *Popular Science News*, Dr. B. W. Richardson, of England, in making some investigations upon the physiological effects of breathing pure oxygen by various animals, has discovered that, by simply passing the gas a few times through the lungs, it becomes "devitalized," or incapable of supporting life, although its chemical composition remains the same, and all carbonic dioxide and other impurities are removed. He also found that by passing electric sparks through the gas it became "revitalized," and regained its usual stimulating effect upon the animal economy. The devitalized oxygen would still support life in cold-blooded animals, and combustible bodies would burn in it as brilliantly as ever. Dr. Richardson considers that while the gas is in contact with the tissues or blood of a warm-blooded animal some quality essential to its life-supporting power is lost.—*National Druggist*, August 15, 1887.

The Effects of Ether on Living Nerves.

Messrs. Vaillard and Pitres are studying neuritis caused by injections of ether in the neighborhood of the nervous trunks of the limbs. These injections have often been followed by stubborn paralysis, and even by trophic disturbance. Experiments made upon guinea pigs show that the anæsthesia and paralysis, which immediately follow the injection, spread rapidly and persist for many weeks or months without either diminution or augmentation. The injection, therefore, determines phenomena identical with those produced by severing the sciatic nerve, of which we can convince ourselves by a microscopic examination. This shows that the nerve is normal *above* the point where the injection has taken effect. At its point (immediate neighborhood) the lesions vary according to the amount of the substance injected. Some hours after the injection the myelin mingles with the axis cylinder, which is then hardly distinguishable, as are also the nuclei of the inter-annular segments. After the fifteenth day the myelin becomes pulvulent and the nerve sheath is regenerated by special evolution. Below the injection the nerve branches undergo Wallerian degeneration after the sixth day, as in nerve section. To sum up, ether determines necrosis of the fibres which it reaches, and acts upon them as a chemical poison. Perhaps by the side of these grave disadvantages we may acknowledge for these injections a favorable action in frequent cases, as when the elongation of the nerves seems indicated.

This study shows several things of practical importance—first, that the frequently recommended perineural injections of ether may give rise to more grave results than has been supposed; and, second, that in some of the relatively rare cases in which nerve-stretching is indicated, the same results may be attained by the injection of ether.—*The Dental Register*, August, 1887.

An Apparatus for the Relief of Writer's Cramp.

This is called the "Kaligraph," by its inventor, the late Mr. Charles Thurber. It consists of an iron frame-work, to which was attached a series of levers so arranged that by making large characters at one angle the characters were reproduced in ordinary size at the opposite angle. It was, in fact, a kind of reversed Pantagraph. Dr. Danna said that all writers's-cramp instruments were based on the principle of resting the groups of muscles most used, and throwing the work upon

other groups. The Kaligraph fulfilled these indications better than any other instrument with which he was familiar. The objections to it were that it was cumbersome and expensive. The speaker showed cuts of all the various forms of instruments for writer's cramp (ten in all) which he had been able to collect. The kaligraph had been in practical use for thirty years, but it was very little known. It had enabled its inventor, who had suffered extremely from the cramp, to write with comfort. He was informed that Mr. Charles Dickens had possessed and used one.

Dr. G. S. Jacoby thought this instrument was only palliative, while Nussbaum's was also curative, and could be carried with one. It compelled the writer to use the abductors.

The President replied that an instrument calling into play another group of muscles of the hand would cause those to be affected after a time.

Dr. Birdsall thought writer's cramp was due to cerebral fatigue rather than to muscular fatigue, and that instruments for overcoming it could be of only limited benefit.—*The Dental Register*.

Sulphur Fumes in Pertussis.

A Norwegian physician named Mohn, discovered after disinfecting the bedding of one of his own children who had suffered from scarlet fever, that another child who had whooping-cough, and who accidentally inhaled some of the fumes of the sulphur, was suddenly cured of the disease. Acting on this suggestion, he has treated other cases of pertussis by placing the patients in a room where sulphur had been burned in the usual manner in which it is employed for disinfectant purposes. He claims that after being put to bed in such a room, the patients awake the next morning cured.—*The Med. Herald*, August, 1887.

Bromidia.

The United States Circuit Court has granted a perpetual injunction restraining the publication of a formula for a liquid medical preparation under the name "bromidia," unless there is also published, in connection with the said words "bromidia," or "bromidio," a statement that the preparation covered by the said receipt is put up and sold by Battle & Co., of St. Louis, under the trade mark "Bromidia."—*Med. News*, July 30, 1887.

Lunacy Regulations in France.

In consequence of certain irregularities revealed by the investigations into the case of Baron Seillières, who, it was alleged, was improperly detained in a lunatic asylum near Paris after he recovered his mental equilibrium, the minister of the Interior, M. Fallières, has issued a circular to all prefects directing them rigidly to obey the enactment which requires them to make periodical visits to all asylums, public or private, within their jurisdiction. It is directed that these visits should be paid unexpectedly, and not less frequently than once a quarter; that patients who desire to leave the asylum should be interviewed, and in every doubtful case subsequently subjected to a special medical inquiry; that the use of the shower-bath as a punishment should be forbidden; that the period of observation should be reduced to the shortest possible time; and that frequent transfers from one establishment to another should be discouraged.—*Brit. Med. Jour.*, August 13, 1887.

Electrified Ice Cream.

Dr. Geo. S. Hull, of Chambersburg, Pa., has found by actual experiment that electricity is generated in ice cream by the friction of the zinc paddles on the contents of the freezer. He has experimented with various mixtures, and found that the presence of fruit or other acids increased the electric action. The doctor concludes that the cases of ice cream poisoning come from the zinc and not ptomaines or tyrotoxin. The doctor is zealously pushing his investigations, and we look for further developments.—*Nat. Druggist*, Aug. 15, 1887.

Distilled Water not good for Eye Lotions.

An English oculist, having noticed that eye lotions made with distilled water were more irritable than when ordinary water was used, found, on further trial, that the irritation was still greater when the distilled water alone was applied. The simple explanation of this was that well or spring water contains salts in solution which make it slightly alkaline, thus rendering it somewhat more neutral to the conjunctiva, a tissue ordinarily bathed in the lachrymal secretion, which contains about one per cent. of solids, chiefly chloride of sodium, or common salt. The addition of two and a half grains of this salt to the ounce of distilled water renders any lotion for the eye more soothing.—*Druggists' Circular*, August, 1887.

A Doctor's Story.

Mrs. Rogers lay in her bed,
 Bandaged and blistered from foot to head,
 Bandaged and blistered from foot to toe,
 Mrs. Rogers was very low.
 Bottle and saucer, spoon and cup,
 On the table stood bravely up;
 Physic of high and low degree;
 Calomel, catnip, boneset tea—
 Everything a body could bear,
 Excepting light and water and air.

I opened the blinds; the day was bright,
 And God gave Mrs. Rogers some light.
 I opened the window; the day was fair,
 And God gave Mrs. Rogers some air.
 Bottles and blisters, powders and pills,
 Catnip, boneset, syrup and squills,
 Drugs and medicines, high and low,
 I threw them as far as I could throw.
 "What are you doing?" my patient cried.
 "Frightening Death," I coolly replied.
 "You are crazy," a visitor said;
 I flung a bottle at her head.
 Deacon Rogers came to me;
 "Wife is comin' round," said he.
 "I really think she'll worry through;
 She scolds me just as she used to do.
 All the people have poohed and slurred—
 All the neighbors have had their word;
 'Tis better to perish,' some of 'm say.
 'Than be cured in such an irregular way.'"
 "Your wife," said I, "had God's good care
 And his remedies—light and water and air.
 All the doctors, beyond a doubt,
 Couldn't have cured Mrs. Rogers without."
 The deacon smiled and bowed his head;
 "Then your bill is nothing," he said;
 "God's be the glory as you say;
 God bless you, doctor; good day! good day."
 If ever I doctor that woman again,
 I'll give her medicines made by men.

*Official List of Changes of Medical Officers of the
 U. S. Marine Hospital Service, for two weeks
 ended August 20, 1887.*

W. H. Long, Surgeon, leave extended six days on account of sickness, Aug. 18, 1887.

C. S. D. Fessender, Surgeon, leave extended thirty days on account of sickness, Aug. 19, 1887.

John Godfrey, Surgeon, granted leave of absence for thirty days, Aug. 17, 1887.

R. A. Glennon, Passed Asst. Surgeon, granted leave of absence for thirty days, Aug. 18, 1887.

W. R. McIntosh, Asst. Surgeon, granted leave of absence for twenty-five days on account of sickness, Aug. 17, 1887.

*Changes in the Medical Corps of the Navy during
 the week ending August 20th, 1887.*

Medical Inspector, S. Robinson, placed on retired list.

QUESTIONS IN THE TREATMENT OF INEVITABLE ABORTION.

BY THEOPHILUS PARVIN, M. D.,
Professor of Obstetrics in the Jefferson Med. College,
Philadelphia.

There are differences of opinion and also of practice in regard to the treatment of inevitable abortion, and especially of that form in which the expulsion of the ovum is incomplete. A brief discussion of some of these differences may not be unprofitable.

It is in many cases difficult, if not impossible, to know that the abortion is inevitable. If the hemorrhage be marked, and fragments of decidua are expelled, or if the ovum be felt at the os, the cervical canal having been so far dilated as to permit its descent, a conclusion often verified by the event may be made, that the pregnancy must be interrupted. And yet these symptoms do not justify the conclusion. For example, I have seen a patient at the third and also at the fourth month of pregnancy, have so profuse a discharge of blood from the uterus that a dozen napkins were required in twenty-four hours, and at times one of these napkins was saturated with blood; nevertheless, the pregnancy continued.

In general, it may be said that only in case the embryo or foetus is dead, and a free rupture of the membranes has been made, or their extensive detachment effected, can the abortion be declared inevitable. The recognition of the death of the foetus is pos-

sible if its life has been previously made known by auscultation; for, having once distinctly heard the sounds of the foetal heart, and then failing to hear them again after careful and repeated examinations, the just conclusion is that the foetus is dead. But in the majority of cases this evidence is not available, for the threatened miscarriage is present before the throbbing of the foetal heart can be heard. A free rupture of the amniotic sac certainly will be followed by abortion; whether a mere puncture with only partial evacuation of the contained fluid will then result in all cases may be considered doubtful; for certainly not only cases of spontaneous rupture of the membranes, and also those of their puncture, in the latter weeks of pregnancy without labor coming on for some time after, have been observed. Even though the membranes have been punctured, or spontaneous rupture has occurred, the fact is in most cases not known to the practitioner. Again, it is rarely that he knows that large detachment of the ovum from the uterus has been made; while such detachment results in hemorrhage, yet, as before indicated, this symptom may occur, and the pregnancy continue. There are two proofs that the abortion is inevitable, which are available in those cases in which the two essential symptoms, viz., uterine contractions and flow of blood, continue for two or three weeks, or more, and these symptoms are, arrested development of the uterus and retrograde changes in the mammary glands. Now that the method of bi-manual examination as a means of obstetric and gynecological diagnosis is so familiar to the profession, it is not necessary to more

than refer to it as available for the recognition of arrest of that increase of size of the uterus resulting from the pregnant condition; in other words, if this organ ceases to grow, the embryo or fœtus is dead. Again, if the enlargement of the breasts, which usually begins at the first menstrual absence following conception, has occurred, and these organs from having been full, plump, and possibly the seat of occasional pain, become shrunken, flaccid and painless, it may be regarded as almost if not quite certain that the pregnancy cannot continue. Here let a word of caution be said. In some cases, by no means frequent, it happens that the breasts after increasing in size in the first months of pregnancy lessen somewhat, and remain thus only partially developed until after labor. But this fact is not frequent, and the condition of the mammæ is by no means that which is observed following the death of the embryo or fœtus.

In threatened abortion we have no two remedies comparable to rest and opium; these are also invaluable in case the miscarriage is inevitable, and many observations have led to the conclusion that the pregnant woman bears opium remarkably well. By this means we lessen one of the dominant symptoms, pain, and indirectly by slowing the circulation, hemorrhage. But the means of especial value as a uterine hæmostatic is hot water injected into the vagina; of course the injections should be copious, and given if the discharge be great, at frequent intervals. One advantage that this treatment presents in abortion is, that it may be employed in cases in which there is hope of continuing the pregnancy—it does not excite uterine contraction so much as it does contraction of blood vessels. By these injections possibly we will render unnecessary in the majority of cases the administration of ergot or the application of the tampon; nevertheless ergot and the tampon are means which may become essential in the treatment, and they are probably most efficient if used conjointly.

Antiseptic vaginal injections should be used twice daily during the continuance of the abortion.

Of course if notable hemorrhage persists in spite of hot water, opium, ergot and the tampon, the indication is plain to empty the uterus by manual or by instrumental means, following the removal of the ovum by antiseptic applications—*e. g.*, injections into the uterus of a 5 per cent. solution of carbolic acid, or of 1 to 2,000, or 3,000 corrosive sublimate solution, or swabbing the intra-

uterine surface with one of these solutions, or with the tincture of iodine, or the introduction of an iodoform tampon. Here let me say a word in regard to the effort to reject corrosive sublimate as an antiseptic in obstetric practice in consequence of mercurial poisoning having occurred in a few cases. In only two of many cases in hospital practice in which 1 to 2000 corrosive sublimate injections into the vagina and into the uterus were employed, have I seen unpleasant consequences result; and these consequences ceased upon discontinuing the remedy. I believe if the uterus and vagina are thoroughly emptied after the injection, none of the fluid being left behind for slow absorption to occur, by following it with an injection of water that has been sterilized by boiling, no injurious results will be seen. Nevertheless it is advisable in all cases where corrosive sublimate solution is used, either in connection with abortion or after labor, to observe from day to day the gums, and the moment these are found red and swollen, to at once discontinue the solution.

As to methods of emptying the uterus in incomplete abortion, that in which only one or two fingers, first carefully made aseptic, are employed is the best; the patient lies upon her back and the physician places one of his hands upon the abdomen to press the uterus down to the fingers of the other hand so that they more readily enter its cavity. If instrumental means be required my preference is for Emmet's curette forceps, if the abortion be within the first ten weeks of pregnancy; many, however, employ a blunt curette.

I hold too, that evacuating the uterus is clearly indicated in incomplete abortion, not only by such hemorrhages as have been mentioned, but by an offensive discharge, for such discharge may foretell septic infection. Many excellent authorities, more especially of the German school, advocate immediate emptying of the uterus in all cases when a part of the ovum remains. Now the objections to this are: First, there may be a twin pregnancy, and one ovum may be expelled and the other retained until complete development is accomplished, and thus the operator in assisting one abortion makes a second one. Second, there is danger of causing a traumatism either in the dilatation of the cervical canal, or by the use of the curette upon the uterine wall. Third, it should be remembered that the uterine decidua, the *decidua vera*, is not fused with that covering the ovum until some time in the fourth month, but is quite firmly united to the

uterine wall; abrupt detachment of it is a violence which may produce more serious consequences than those which result from its gradual breaking down and discharge, nature's method of casting it off.

Let it be called conservatism, if any one chooses, nevertheless my faith and practice are in cases of incomplete abortion to wait, if the os be closed, until the symptoms which have been mentioned occur—without one or both of these, no interference, but an armed expectation and the regular use of antiseptic vaginal injections. It is worthy to be observed that the advocates of immediate interference sustain their position by adducing instances in which continued hemorrhages, or offensive discharges, and even septic infection followed delay in emptying the uterus. Certainly, and cases presenting such symptoms demanded earlier interference; if the practitioner had been wise enough to be warned by the first two, and proper response was made to the warning, the third would scarcely be known. The multiplication of cases of early incomplete abortion in which hemorrhage persisted for weeks, and then fragments of membrane or of placenta being removed the patient got well, do not prove that the practice of immediate interference, that is the artificial complete removal of the ovum is demanded in every case of abortion in which spontaneous expulsion does not occur. Certainly there are advantages in a prompt and perfect deliverance, but it is not exempt from dangers if violence is used in effecting it, and in some instances it may abruptly end a pregnancy which under other practice might continue to its normal termination. The advocates of immediate interference claim the best results. Carlyle has said, "Granted, the ship comes into harbor with shrouds and tackle damaged; the pilot is blame-worthy, he has not been all-wise and all powerful; but to know *how* blame-worthy, tell us first whether his voyage has been round the globe, or only to Rams-gate and The Isle of Dogs." So we would like to know the number of cases treated in this particular way prior to giving an opinion as to its value. Further, before the question can be finally settled, a sufficiently large number of cases thus treated must be compared with a like number in which no interference with the process, so far as the uterus is concerned, is made without symptoms require it. Of course at the time of the miscarriage make it complete if possible without injury to uterus—let the interference be digital rather than instrumental, unless the former fails and hemorrhage persists; but

that time passed and part of the ovum being retained, the os closing, I believe it better to wait until distinct call for action is given. There is a middle ground between immediate intervention and absolute expectancy; and in that ground, my faith is, the path of safety lies.

One of my most valued professional friends, an able, conscientious and distinguished practitioner, in reference to this special view of the treatment of abortion, as well as the management of labor, has written me that my methods are too artificial and I do not trust enough to nature, adding, that in a practice of fifty years—and I know that during a great part of that time his practice has been large—he has not lost a single woman as a consequence of labor or from miscarriage. I do not know, but it is quite probable this gentleman has attended 2,000 cases of labor, for as the result of observation and of inquiries my conclusion is that the general practitioner, even if his practice be large, does not have more than an average of forty cases of confinement a year. Of course there are exceptions, some devoted exclusively to obstetric practice, or connected with maternities, or having a large *clientele* of the poor, or at least of those in very moderate circumstances, may count in the course of their professional lives three or four thousand obstetric cases. But for one who can thus number his cases, there are ten who are under the average that has been mentioned. If one were to take the extravagant and improbable statements of some few physicians, who we will suppose guess at a number and multiply it by two, so that nothing shall be lost as to the number of labors they have attended, and then make it the standard for the profession in general and for midwives, the population of this country would be increasing in such a frightful ratio that Malthus would not rest in his grave, or else there would be a slaughter of infants in comparison with which that by Herod was infinitesimal. In this department of obstetric statistics I believe there are more unfortunate mistakes than in any other.

Returning from this digression, the number of abortions attended by one who has had charge of 2,000 cases of labor will be not less than 250, or according to some estimates of the relative proportion between miscarriages and labor at term, even 600 or 700. Bush's proportion is 1 to 5.5; Whitehead's 87 out of 100, and Hegar's 1 to 8. Taking the smaller of the numbers mentioned, there certainly is a strong argument

for the expectant treatment of abortion in the fact that 250 thus treated recovered.

But I do not want to urge such treatment as invariably the best, for expectation has its limits, the definition of which this paper has endeavored to present.

ACETONE AND DIACETIC ACID IN THE URINE.

BY J. P. CROZER GRIFFITH, M. D.,
PHILADELPHIA.

Assistant Physician to the Hospital of the University of Pennsylvania.

The detection of these two substances in the urine and the comprehension of their clinical significance, is more and more becoming, not a matter of purely scientific interest only, but one of practical value.

ACETONE.—Acetone is a colorless, volatile fluid, with the chemical formula C_3H_6O . It is formed in nature only in the animal organism, and is found there in very minute quantities under physiological conditions. The amount is so minimal that it may be disregarded for clinical purposes.

There are several chemical tests for acetone, but as nearly all of them need to be applied to the distillate from the urine, and are, therefore, too troublesome for everyday use, I shall only describe that of Legal, which is: dissolve a few crystals of sodium nitro-prusside in a little hot water in a test tube. Add some drops of this to the urine to be examined, and then make the mixture distinctly alkaline with an excess of liquor potassa. A red color is at once produced, but fades after a short time, and has no significance whatever. After it has disappeared add a few drops of acetic acid, whereupon, if acetone be present a deep violet or brownish-purple color will appear wherever the acid has penetrated. The color often develops slowly, and becomes more intense in the course of a few minutes.

This test is not difficult for small amounts, but it is the only one which we can use with the urine itself.

Pathological acetonuria, *i. e.*, where the amount exceeds gr. 1-6 in the total quantity of urine passed in the 24 hours, may be divided into several classes, following somewhat the classification of Von Jaksch:

1. Febrile acetonuria.
2. Diabetic acetonuria.
3. Acetonuria of carcinoma.
4. Acetonuria of inanition.
5. Acetonuria in certain psychoses.
6. Idiopathic acetonuria.

All cases of continued high fever, of whatever nature, are accompanied by the presence of acetone in the urine, and the degree of acetonuria corresponds largely to the elevation of temperature. Diabetic acetonuria is another very common form. It appears to have no relation to the degree of glycosuria. Its development in diabetes is sometimes ushered in by headache, loss of appetite, disordered digestion, a sense of weakness and other unpleasant subjective symptoms; but these soon disappear, though the acetonuria persists. It seems to be without clinical significance, except that it is more apt to occur in grave cases, and is a frequent precursor of diacetic acid in the urine. Acetonuria is not infrequent in carcinoma of the stomach and bowels, even before cachexia develops. Its onset is accompanied by symptoms similar to those seen in diabetic acetonuria. Cachexia probably develops earlier in those cases in which an abnormal amount of acetone can be detected. Inanition from whatever source is very often accompanied by large amounts of acetone in the urine. This substance has also been detected in the urine in certain instances in psychoses attended by great mental excitement. The sixth class contains those cases in which there is an auto-intoxication by acetone. They are instances of acetonæmia, and though they occur with great rarity, it is well to be on the lookout for them. They are characterized in some cases by restlessness, excitement, and delirium, and then by coma and death; while no cause can be ascertained, but the urine is found loaded with acetone. In other cases there is extreme languor and other indefinite symptoms. In a few instances reported by Von Jaksch epileptic attacks have appeared, dependent solely on the presence of acetone in the system.

DIACETIC ACID.—Diacetic acid is chemically not far removed from acetone; but its clinical significance is far different, and its presence in the urine is a most dangerous complication. It is a compound of acetone with one of the organic acids, probably formic acid. As it is very readily decomposed into acetone and carbonic di-oxide, the urine obtained for examination must be as fresh as possible.

The test for diacetic acid is very simple. If a few drops of a solution of the chloride of iron be added to urine containing the acid, a Bordeaux-red color will be at once produced. The urine will also *always* answer readily to the tests for acetone, since in the decomposition produced by the addi-

tion of the test-reagents for this latter substance acetone is produced and the diacetic acid is destroyed.

But the matter is not quite so simple as would at first sight appear, since numerous other bodies may at times occur in the urine and produce the same red color. The fact is especially to be noted that the urine of patients to whom thallin, antipyrine, salicylic acid and carbolic acid has been administered will give this reaction. The following procedure is therefore to be advised: Add a few drops of the iron solution to some quite fresh urine in a test-tube. If a very heavy precipitate of phosphates occur, filter this and test the filtrate again. If the Bordeaux-red color is produced, a portion of the urine is to be boiled and another portion acidulated with sulphuric acid and shaken with ether. If the red color soon disappears on boiling the urine in which the test has already been made; if it occurs not at all or but faintly in the urine prepared by boiling; if finally the red color produced by testing the ether extract fades within 24 hours, while at the same time the reactions for acetone in the native urine are very distinct, we have to do with diacetic acid. I wish here to call attention to a mistake still frequently made with reference to this substance. For example, in a clinical lecture by a very well known clinician, reported in one of our medical journals not many months ago, the lecturer referred to the well-known *red color produced by acetone* when a solution of the chloride of iron is added to the urine containing it. It is true that some years ago it was supposed that acetone gave this reaction, but we now know that it is an entirely different substance.

The same classification of diaceturia may be made as in acetonuria:

1. Febrile diaceturia.
2. Diabetic diaceturia.
3. Diaceturia of carcinoma.
4. Diaceturia of inanition.
5. Diaceturia in certain psychoses.
6. Idiopathic diaceturia.

Diaceturia accompanying continued high fever is rare in adults, and indicates that the disease will probably run a malignant course. In children it is more common, and possesses no unfavorable prognostic value. Diabetic diaceturia is a most unfavorable symptom, and is the precursor of diabetic coma. It is sometimes ushered in by depression and a disposition to sleep; coma may at once follow, or the symptoms may disappear though the diaceturia remains, and the patient is liable at any time to develop coma

and die. Usually there is no relation between the diaceturia and the degree of glycosuria. Diaceturia in carcinoma may also occur and lead to coma. It has also been rarely seen in certain psychoses and in states of inanition. Idiopathic diaceturia, in which there is an auto-intoxication from the drug, is rare in adults, and a highly dangerous condition. It begins with vomiting, restlessness and dyspnoea, and terminates in coma and death. In children it is oftener seen and is usually of less import. Constipation and vomiting, with a thickly coated tongue are present, attended by an enormous quantity of diacetic acid in the urine.

Clinical and therapeutical indications.—The clinical indications have been already discussed. The presence of acetone in the urine need, as a rule, cause no special anxiety. The occurrence of diaceturia, on the other hand, is always a grave symptom except in some cases in children. It is very important to know of its presence, on account of its prognostic indications. In the present state of our knowledge we are unfortunately unable to hinder the development of diacetic acid in the system, or to remove it when formed. Neither diet nor drugs have any effect on it.

Lépine disputes Von Jaksch's claim that diacetic acid is the cause of coma in diabetes, and believes that it is B-oxybutyric acid which is at fault. It is certain that the two substances are chemically very closely allied; but unfortunately the experiments with intravenous injections of a solution of sodium bi-carbonate with the object of preventing the production of B-oxybutyric acid and the development of coma have not been attended with signal success. So whatever may be the true cause of the coma, we are as yet unacquainted with means to prevent it.

As acetone, and hence also diacetic acid, is supposed by some to arise from the decomposition of albumen, it would be well in all cases of auto-intoxication with either to empty the bowels by means of a purge, on the ground that the poison is possibly being absorbed from the intestinal tract.

123 South Eighteenth Street.

—A medical journal says: "The application of a bit of ice to the lobe of the ear will stop hiccupping." All a man who is accustomed to hiccupping has to do, then, is to carry a bit of ice about in his waistcoat pocket, and he can cure himself instantly.—*Chemist and Druggist.*

TOBACCO ; SAFE AND UNSAFE METHODS OF EXHIBITION.

BY ENOS T. BLACKWELL, M.D., CEDARVILLE, N. J.

The authors and compilers of the United States Dispensatory were gentlemen of the highest attainments, and did not fail in properly estimating the delicacy of their task of assigning to each article of the *Materia Medica* its just rank as a curative agent; nor in pointing out the line at which it ceased to be beneficial and verged toward danger.

The desire of retaining in the list a drug which was capable of much good in the hands of the prudent and experienced, led them to hedge about certain articles in such a way as to impel the cautious to err by excess of prudence; but this anxious care had little effect in deterring the inexperienced, the bold, and the rash from risking everything in the hope of signal and triumphant success.

There is no drug included in the *Materia Medica* of which it is more necessary to be careful in regard to its introduction into the human system, a carefulness which shall result in the absorption by the tissues of just the amount required to accomplish a therapeutical result and no more, than tobacco. There is one method of exhibition spoken of by medical writers, in which this exactness can rarely be attained; in which the drug once given passes from the control of the person administering it, and is liable to cause the gravest condition, even death; I mean the injection of the infusion into the rectum.

Though this form of application is mentioned by the late Professor George B. Wood as permissible, the warning which he gives shows his fears as to its use. It would have been better, perhaps, if his sanction had been withheld, or that his admonition had been set in the boldest type. With this permissive sentence eliminated from the text, and the word "or," which follows, the directions may be pronounced admirable: "As a narcotic it is employed chiefly to produce relaxation in spasmodic affections. For this purpose (the infusion or smoke of tobacco, or), the leaf in substance, in the shape of a suppository, is introduced into the rectum in cases of strangulated hernia, obstinate constipation from spasm of the bowels, and retention of urine from spasmodic stricture of the urethra."¹ He adds this wholesome advice, which is of the highest importance, and

should receive the gravest emphasis: "It should be used with great caution. This remark is applicable to all the modes of using tobacco, particularly to the injection of the infusion into the rectum."

There is no suggestion in the dispensatory article of an antidote to tobacco, and the measures to be taken in case of poisoning by it are stated in very few words. As they occur at the close of a long paragraph, they do not stand out as distinctly as is desirable: "In cases of poisoning from tobacco, the indications are, after evacuation of the poison, to support the system by external and internal stimulants, and to allay irritation of the stomach by opiates." The directions of Pereira are fuller and more specific: "If the poison has been swallowed, let the contents of the stomach be withdrawn as speedily as possible. No chemical antidote has been demonstrated, but the vegetable astringents (infusion of nutgalls, green tea, etc.) deserve attention. As anti-narcotics, the vegetable acids and coffee may be administered. When the depression of the vascular system is extreme, ammonia and brandy may be administered with good effect, and frictions employed. Artificial respiration should not be omitted, when other means have failed."¹

It may be here stated that tannin, the active principle of the vegetable astringents mentioned by Pereira as worthy of attention in counteracting the effects of the poison, is claimed by some authors as a chemical antidote to nicotine.²

So little is tobacco used by medical practitioners of the present generation, that few of them, perhaps, have witnessed the utter relaxation which it produces in the human system—an unharnessing, so to speak, of the muscular apparatus, which follows the administration of no other drug. While yet young in the practice of my profession, I encountered two desperate cases of incarcerated hernia, which called for the most powerful relaxant known to medicine. I chose tobacco; and was happy in eschewing the infusion, and using the leaf,—the ordinary cut tobacco—as a suppository. The results, I cannot but esteem brilliant, even in the light of the appliances of the present day,—relief being obtained in a very short space of time. On one occasion, in which a hernia in one of the cases referred to had resisted for many hours the best directed efforts of some capable physicians, I was pleased to find the protrusion released within an hour by the aid of

¹ Pereira, *Materia Medica*, Philadelphia, 1845.

² *Lersch*, quoted by Von Beek: *Vegetable Poisons*, Art. Nicotine: Von Ziemssen's *Cyclopædia*.

¹ *United States Dispensatory*.

the suppository. So complete was the paralysis of the sphincter ani, that it had released its grip of the tobacco, which was found lying outside,—the anus being open sufficiently to admit a finger. The application had proved to be self-regulating,—coming away when no longer needed. The amount of the drug used was about sufficient to fill the bowl of the common smoking-pipe,—estimated at 12 grains. The particles were held together by threads wrapped about them,—the ends of which being allowed to protrude afforded a suitable means of withdrawal. Professor Henry H. Smith showed his class (1868-9) how to use the “fine cut” wrapped in lace-like tissue.

In the MEDICAL AND SURGICAL REPORTER, March 24th, 1860,¹ I related two cases of strangulated hernia to which reference has already been made, in which the incarcerating structures gave way under the use of the tobacco suppository. They are very striking, and I think, instructive cases; and, as they will be new to the greater part of the present race of practicing physicians, I take the liberty of reproducing them.

J. C., aged 75 years, had an inguinal hernia of long standing. It became incarcerated on the 29th of August, 1854. The size and tension of the tumor were extreme. All known methods of reduction unsuccessfully exhausted, I introduced a suppository of tobacco. In a short time, the tumor had palpably relaxed, and soon entirely yielded. On the 4th of September following, he had a relapse. By all the usual means, skillfully and perseveringly applied by two neighboring practitioners, together with the exhibition of chloroform, it proved wholly irreducible. I saw him at 4 o'clock P. M., and determined to try the remedy which had once before relieved him. In about one hour from the employment of the suppository, the tension was so much lessened, that a considerable part of the protruded mass was returned by taxis; and soon after, whilst waiting events, the remainder of the tumor spontaneously subsided.

J. M., aged 70 years, has also had inguinal hernia from youth. Twenty years since, it became strangulated, and relief was obtained by an operation. In November last [1859,] at 7 o'clock A. M., he had a protrusion, and was unable to return it. He was at once seized with excruciating pain in the abdomen. In his own nervous language, “the pain went right to his heart.” Syncope followed, and he lay as one dead; and such his friends reported

him. On my arrival, at 11 o'clock A. M., he lay motionless and deadly pale. Consciousness had returned, but his breathing was imperceptible. His pulse was soft and regular. The tumor equalled in size the head of a new-born infant. It was tense to the last degree and elastic. The patient was confident the operation must be repeated, and accepted that as an alternative. After trial by taxis, sufficient to prove its utter inefficiency, I applied the tobacco, and calmly awaited restoration. In about an hour, the incarcerated part was liberated; and, unassisted, swept into the cavity of the abdomen. There were no unpleasant sequelæ in either case.

All the cases reported of poisoning by this drug have resulted, so far as I have learned, from faulty methods of exhibition; or, from the use of an inordinate dose. In the cases stated by Pereira,¹ as coming under the notice of Sir A. Cooper, Sir Charles Bell, and Dr. Copland, one drachm in clyster proved fatal, in each case. Pereira also relates that a half-drachm in infusion has caused death. Desault has seen a like result from an enema of the smoke of tobacco. The infusion of tobacco² is made by adding one pint of boiling water to 60 grains of tobacco, macerating for one hour and straining. The direction is: “Only one-half of the pint of the U. S. P. infusion should be employed at once; and, if this should not produce relaxation in half an hour the remainder may be injected.”

Pereira says, “The cautious practitioner will not use more than 15 or 20 grains.” If he be wise, as well as cautious, he will avoid both the infusion and the smoke,—employing only the leaf. This can be watched, and removed when no longer useful; and any liability to excessive action be thereby averted.

GALVANO-PUNCTURE IN TUBAL PREGNANCY.

BY WILLIAM R. D. BLACKWOOD, M. D.,
OF PHILADELPHIA.

I have, in various published papers, referred to the dangerous method under which electricity is used in Europe in extra-uterine pregnancy, and more particularly to the dependence placed upon *galvano-puncture* in England. The whole subject of electrolysis in ectopic gestation is apparently enveloped in Great Britain in a fog as impenetrable as

¹ Vol. iii, p. 559.

¹ *Materia Medica*, loc. cit.

² *United States Dispensatory*, 13th edition.

that which our London confreres are favored with so often through their unique atmospheric peculiarities. It is believed that the typical highlander's cranium is impregnable to the reception of new ideas short of a surgical operation, and it would appear that no amount of clinical evidence, as furnished from this country is of any value to the average British practitioner toward establishing the certainty of result, and the safety of procedure, in destroying the embryo in ectopic gestation up to say, the fourteenth week. After that period undoubtedly laparotomy is the correct thing to do. A recent contribution to the *British Medical Journal*, by Dr. Percy Boulton, physician to the Samaritan Free Hospital gives particulars of a case, the nature of which beyond doubt was that of ectopic gestation at about eight weeks. After watching and consultation with other physicians for a month, during which time the tumor necessarily grew much larger, electrolysis was decided upon as the remedy. Three curved needles long enough to reach the tumor and to extend outside the vagina (but how thick is not stated,) were introduced. The needles were coated with shellac (all except an inch and a half of the pointed ends) as the insulating medium, and the positive pole was connected with them, the negative being applied to the thigh of the patient and "moved about for the space of six minutes." Difficulty was experienced in removing the needles owing to their roughening under the current from thirty Stohrer cells. The subsequent history is that of peritonitis, death ensuing in twenty days.

I do not think there is much room for doubt as to how the fatal result was brought about. No attainable coating with shellac will insulate needles under the circumstances narrated. The roughening resulted from scaling of the cover together with deposition on the purposely exposed points as is usual in puncture, for example, in aneurismal sacs. Unless adhesion through inflammation existed (which is not stated), it is probable that the peritoneum was wounded, and it is possible and probable that six such points were created by the needles all of which were exposed to the caustic action of the current. Moreover the tube was weakened by the puncture and opportunity given for escape of contained or resultant fluids into the peritoneal cavity. The doctor himself thought that rupture took place after supuration.

The opinion is given in the article that galvanization without puncture would involve four or five daily applications of half

an hour each from say twenty cells. Further, the fear is stated that any "shock which would kill a fœtus of four or five months would endanger the life of the mother." Again Dr. Steavenson is quoted as follows: "A powerful electric shock causes the death of the adult by its stimulation of the inhibitory fibres of the pneumogastric (?); but a fœtus has no inhibitory apparatus, at two or three months, at any rate the nervous apparatus is not fully differentiated, and it is probable that a shock would affect the mother rather than the embryo." The reasoning throughout the article is based on the ideas above quoted.

In considering the subject it occurs to me that with all due deference to Steavenson, First, He is wrong in his opinion that a fœtus has no inhibitory apparatus; just as women are who claim that there is no life in the embryo early in its development, therefore no wrong is done in murdering it. I tell such women that if it is not alive it won't grow, and they needn't care. At three months a fœtus has inhibitory fibres, minute enough to escape our observation no doubt, but all the same they are there, and they grow. Not only is differentiation obscure in its nervous development, but also fœtal tissues are of necessity very immature, and it is because of this low grade of development that electricity is so powerful an agent in destroying its vitality. The term "shock," as popularly understood, is not applicable to electrolysis as now considered.

Two methods are open to us in studying the therapeutic effect of remedies—the theoretical, and the experimental or practical. Before I ever treated an extra-uterine pregnancy personally, I knew from repeated experience just how an accidental, powerful shock in the way of instantaneous static discharge affected me, and I imagined that the disruptive effect from a Leyden battery would be exactly the thing for the occasion. Unfortunately static electricity has a will of its own, and unlike dynamic electricity it is hard to restrain within given lines. Many a time sparks would skip around upstairs from telephone and bell circuits to the sewing-machine or other metallic object when I was using the static machine in my office, and yet everything is insulated thoroughly. Consequently I would not rely upon this form at all. Faradism, on the other hand, is controllable, and will produce all the effects obtainable from static electricity; therefore, when my chance came to try the method I employed the induction current as thus obtained, and with perfect success. From what I have learned since

then, in additional cases of my own and study of those reported by other operators, I place dependence upon results actually obtained in preference to the theories of those who have not done any such work, no matter how eminent these gentlemen may be as gynæcologists or general practitioners.

Secondly. I hold that Faradism is indicated because it acts with greater energy upon the embryo than galvanism. My reasons for thus thinking are these: Galvanic currents are *diffused* more widely (in lateral lines) in passing through tissues, however near the poles may be, than induction currents. Galvanism does not act *mechanically* on the tissues so much as Faradism when the current is uninterrupted. Anectrotonus and catelectrotonus extend only a short distance from the rheophores under the electroforce developed in operations of the nature considered. The *chemical* or caustic effect is not decided except at the points of contact; hence the European tendency to carry the contact into the sac by needles. Rapidly interrupted or reversed galvanic currents are painful as applied to the female pelvis, whilst the opposite is true of Faradism.

Thirdly. I believe that the death of the embryo is produced by tetanization of its whole mass, and by molecular disintegration consequent upon rapid reversals of polarity, as happens in Faradic high-tension currents. Abundant experiment has taught me that Faradic currents absolutely unbearable in other parts of the body, can be borne not only with impunity, but with little discomfort, as applied to extra-uterine foetations, viz.: One pole intra-vaginal or intra-rectal, and the other firmly pressed down over either ovary, tube, or upon the uterine fundus in non-pregnant women. I have repeatedly passed a one hundred cell current in this manner for fifteen minutes without any injury to the patients. The maternal tissue involved in the current in ectopic gestation is small in extent, but the *whole* embryo is encompassed if proper manipulation is observed.

To be effective the maximum dose must be given *at once*, it must be *long continued* in that sitting, say for an hour or more. Short doses, though given daily, permit recuperation, the mass may still grow larger and the tube thinner, thus endangering the patient from rupture and hemorrhage. Delay on any account is to be deprecated in these cases.

With successful results in five cases of my

own, and with the knowledge obtained through study of reports by others, I feel no hesitation in saying that it is not simply a waste of time to experiment with galvanopuncture, but it is criminally adventuring the woman's life. Death must in the end come to the child or its mother; it really comes to both in a large majority of cases when the condition is unrecognized, when left to nature's efforts, or when not promptly treated.

Prompt treatment means early diagnosis and instant interference. The pregnancy must be arrested with absolute certainty, and two ways only present themselves to my comprehension. One is laparotomy, the other electrolysis. In the hands of a Tait abroad, or Kelly at home, many cases will, thus treated, do well; in the hands of the general practitioner the mortality would, undeniably, be very high. To any man of ordinary common sense, and without special aptness as an electro-therapeutist, electrolysis is no more mysterious or difficult to manage than is vaccination, whilst to the woman it is less dangerous than delivery by forceps. If this be so (and I do not believe that successful contradiction is possible in an honest discussion of the subject), why should a man whose business it is to save life, endanger, nay, fearfully imperil it, by any such procedure as that depicted in the report upon which this paper is based? To the credit of America it is well that the electric treatment of extra-uterine pregnancy has, so far as most reports show, been performed on a sensible basis. Some errors have, of course, crept in through the lack of knowledge of electro-therapeutics possessed by many physicians, but attention is now being paid to the high value of electric force in medicine; and as I have for more than twenty years past used my pen and voice to further its claim to professional notice, I am glad to note the progress thus exhibited. During the period named, I have repeatedly been asked if it was not an error to urge, as I did, currents of high electro motive force, particularly in gynæcological work. I never have had patience with homœopathic doses of anything, and when five to twenty milliamperes was indicated as the extent of current to be given in work of this nature, I wondered how any result could follow such low power in the hands of those narrating the cases. A late gynæcologist seemed incredulous when some ten years ago I spoke of employing currents of one hundred milliamperes, and yet I then frequently went to one hundred and seventy-five. Now I do not

hesitate at two hundred and fifty in a case of ectopic gestation, or in accessible fibroids.*

Apostoli has lately awakened the profession to the safety of high force in uterine electrolysis, and perhaps his example may do something to stiffen the weak-kneed brethren abroad in this respect. If anything can turn their thoughts towards the consideration of localized Faradization of high tension in extra-uterine pregnancy it will be a blessing to British womanhood. A long series of experiments during two years past, in the study of electricity as applied to the instant extinction of life, has confirmed my long-held views as to the safety of so-called high power when definitely localized, but the further consideration of this matter is deferred to another time.

A CASE OF PUERPERAL ECLAMPSIA; RECOVERY.

BY LLEWELLYN ELIOT, M.D., WASHINGTON, D.C.

Mary T., white, aged 18 years, unmarried, of strong physique, was delivered of her first child on the morning of the 12th of August, at ten o'clock, after a labor of eleven hours. The second stage was slow. The case progressed favorably until about four o'clock in the evening of the day of delivery, when convulsions came on. The first was well marked and lasted twenty-five minutes; the second occurred at 4:50, cyanosis very great; the third, at 5:15, lasting twenty minutes, chloroform being administered by inhalation; the fourth, at 5:40, lasting twenty-five minutes; the fifth, at 6:25, lasting twenty minutes. Venesection was now decided upon, chloroform was administered, and twenty ounces of blood taken from the arm. The sixth convulsion occurred at 7:20, lasting fifteen minutes, chloroform inhalation again used, and morphia sulphate gr. $\frac{1}{4}$ given hypodermatically. The seventh occurred at 10:10 P.M., lasting ten minutes; the eighth, at 12:35, lasting five minutes, followed by great restlessness and intermittent pulse; the ninth, at 1 A.M., (August 13,) lasting three minutes; pulse was then double; at 1:25, morphia sulphate gr. $\frac{1}{4}$ again given hypodermatically. At 2:20 the patient was still very restless. The tenth occurred at 2:48, and lasted five minutes. I then ordered the following prescription:

*I always employ galvanism to produce absorption after the destruction of an embryo by Faradism, or to reduce exudations consequent upon plevic inflammation.

R Elaterii..... gr. $\frac{1}{3}$
Hydrarg. chlor. mit..... gr. iv
Ft. pulv. no.j
M. Sig.—Give at once and repeat in four hours if necessary.

About the same time the catheter was passed, and $\mathfrak{z}$ xij of very dark urine were drawn off, which was three-quarters albumin. At 4:30 A.M., a convulsion was aborted by chloroform inhalation; afterwards she was perfectly rational, expressing herself as better, but the powder had not operated. The eleventh convulsion was at 4:48 A.M., lasting five minutes; the twelfth, at 5:05, lasting three minutes; the thirteenth, at 7:20, lasting three minutes, at which time the powder was repeated; the fourteenth, at 8:30, lasting three minutes. At 9:45 the head was shaved and an ice bag applied, to be continued for fifteen minutes at a time. At 9:50 the following was ordered:

R Ol. terebinth.
Ol. ricini..... āā $\mathfrak{z}$ j
Tinct. asafetidæ $\mathfrak{z}$ ij
M. Sig.—Add to one quart of water and use as an enema.

The fifteenth convulsion occurred at 3:10 P.M., lasting two minutes. The bowels were then moved, the urine passed, and the patient became quiet. The sixteenth convulsion was at 6:40 P.M., lasting three minutes; the seventeenth, at 7:40 P.M., at which time the pulse was 134, temp. $102\frac{1}{2}$ F., resp. 54 and irregular; head very hot, while the discharges had stopped. This was the last convulsion the patient had. The next observation was made at 3 P.M., August 14, when the urine yielded but one tenth albumin, and the patient had headache. Morphia sulphate gr. $\frac{1}{4}$ was repeated. August 15, 1:10 A.M.: She was very wakeful, had no pain, morphia sulphate gr. $\frac{1}{4}$ hypodermatically; 12:45 P.M., bowels had again moved, the discharges again appeared, but the patient still had much headache. I ordered:

R Potass. bromid..... $\mathfrak{z}$ iv
Aque fontan..... $\mathfrak{z}$ ij
M. Sig.—Tablespoonful three times a day.

From this time she improved rapidly until the date of her discharge from treatment, September 20th. Beginning with the third convulsion, chloroform was administered to control each convulsion. To clear away the albumin the following was ordered:

R Potass. acetat..... $\mathfrak{z}$ iv
Infus. digitalis ad..... f $\mathfrak{z}$ vj
Spt. ætheris nit. f $\mathfrak{z}$ vj
M. Sig.—Tablespoonful three times a day.

Puerperal eclampsia occurs during the latter months of pregnancy, or during, or

after parturition, proving at times most formidable. Whether premonitory symptoms, such as dizziness, stupor, headache, irritability, œdema of the subcutaneous cellular tissue have occurred or not, the attacks are sudden and epileptiform in character. The more violent the attacks, the shorter the duration of the intervals. Labor frequently results from the nervous shock and general disturbance. When they appear during labor the pains are increased in force and frequency, since all the muscles partake of the convulsive action. The mortality of eclampsia occurring before and during labor is about one in four; after labor about fourteen per cent. The pathology of eclampsia, after much discussion, is still unsettled, although the urinary origin is generally accepted. The treatment consists in venesection, pressure on the carotids, the administration of strong purgatives, inhalations of chloroform; chloral hydrate and bromide of potash by the mouth, the subcutaneous injection of sulphate of morphia, inhalations of nitrite of amyl, injections of hydrochlorate of pilocarpine. Of these modes the inhalations of chloroform, with the internal administration of chloral hydrate and bromide of potash accompanied by a purgative are the most trustworthy, although sulphate of morphia and hydrochlorate of pilocarpine have afforded me good results. In one case where gr. $\frac{1}{8}$ of hydrochlorate of pilocarpine was given hypodermatically and repeated, its action was too depressing; still Braun has given gr. $\frac{1}{2}$ with success. If the pilocarpine were combined with the sulphate of atropia in appropriate doses, its over-action would be prevented. Blood-letting, which at one time was the sheet anchor in the treatment of these cases, was abandoned, to again become a recognized agent. Strong as is the evidence in favor of chloroform, its abuse will, as happened with venesection, tend to bring discredit upon it. It is seldom necessary to produce deep anæsthesia. Chloral hydrate in combination with bromide of potash is more continuous in its action. With the allied assistance of these remedies and careful watchfulness, the rate of mortality will continue to decrease.

510 E street, N. W.

Colorless Tincture Iodine.

Dr. Brown, of Mountain Home, Ark., says colorless iodine may be made instantaneously by adding four drops of carbolic acid to the ounce U. S. Disp. formula of equal parts of iodine and aqua ammonia.—*South. Dental Jour.*, July, 1887.

SOCIETY REPORTS.

MEETING OF THE OBSTETRICAL SECTION OF THE BRITISH MEDICAL ASSOCIATION AT DUBLIN.

Special Report to the MED. AND SURG. REPORTER
by E. S. MCKEE, M. D.

Discussion of Puerperal Fever.

Introduced by W. S. PLAYFAIR, M. D.,
F. R. S. P., LL.D., Professor of Obstetric
Medicine at King's College Hospital.

The subject which I have the honor to introduce to you for discussion cannot fail, I think, to interest all upon whom the responsibility falls of attending women in labor. The prevention of the scourge of midwifery practice, septicæmia, is one of the most important duties. In the short space of a quarter of an hour allotted me, it will be impossible to do more than lay down a few general rules which should guide us. In lying-in hospitals since the revolution of antiseptics, a marvelous change has been effected. I am more particular to-day to insist on the prevention of puerperal disease in *private and domiciliary practice*. In the well conducted lying-in hospital of to-day, a woman is actually as safe, if not safer, than if confined at home in a large house and surrounded by all the comforts money can procure. The great Rotunda Hospital of this city, as well as the lying-in institutions of London, Paris, and St. Petersburg as well as other continental cities, prove what I have said. There is nothing in the history of medicine more remarkable than the change in these institutions since the adoption of the life-saving principles of Lister. I doubt if such a thing can be found now as a hospital for lying-in in which antiseptic rules have not been introduced, and in which similar good results have not followed it. Though recognized and practiced in public practice, I doubt if even yet antiseptic midwifery is at all general in private practice. Called to see septic cases as a consultant, I very seldom find that the practitioner in attendance has followed out the rules in so general use in lying-in hospitals. Perhaps when the younger class of practitioners get more into the practice it will be different, but with the bulk of men now in practice no special care is taken. In civil practice similar care and precautions to those adopted in institutions—a matter of

no very serious difficulty—should almost wipe this scourge out of existence. Fritsch daily dressed a putrid wound in the person of his brother for a whole year, and at the same time daily performed two or three obstetric operations, and by a vigorous antiseptic has not had a single case of septicæmia during the whole time. To show how simply this may be done, and to elicit your views on this subject, is my object to-day. I have no time for argument, and must perforce be brief and content myself with dogmatic statements. To prevent puerperal fever we must have an intelligent idea of what it is, how it originates, and how it may be conveyed to the patient. Unless we are agreed on these points we are not likely to come to any conclusion of value. I take it to be now almost universally admitted that puerperal septicæmia is practically the same thing as surgical septicæmia. A disease caused by poison absorbed through the genital tract into the system, which poison may originate *de novo* or be conveyed to the patient from without by septic matter being brought in contact with her. We should manage her so as to reduce the chance of absorption to a minimum by closing as much as possible the channels through which septic matter is to be absorbed by thorough and permanent contraction of the uterus, and by lessened absorptive surfaces, offered by perineal lacerations and the like. How customary it is to find the binder hurriedly applied, with the uterus imperfectly contracted, remaining large and flabby underneath it, distended with clots which frequently breed mischief. I practice and teach never to remove the hand from the uterus for at least twenty minutes after the removal of the placenta, keeping up a continuous, though not rough, rubbing or kneading. I believe it also good practice at this time to administer a large dose of ergot, and, if contractions do not set in, to give a hypodermic injection of ergotine or ergotinine. Personally, I have never seen any harm result from the routine administration of ergot.

As to *perineal lacerations*, I think the rule should be absolute that the perineum should be inspected after labor, and that every tear more than a slight laceration of the fourchette, should be closed with cat-gut or wire suture, first cleansing thoroughly with the bichloride of mercury solution, and subsequently dusting with iodoform night and morning. Thus any chance of absorption through the bared perineal surface is avoided, and complete healing is insured.

Most important, however, are the *antiseptic*

precautions by which we are to prevent the poison being introduced from without. This, indeed, is the essence of the whole matter. The vast majority of cases of puerperal septicæmia, to my mind, arise directly from poison carried to the patient from some preventable accident. This is an unpleasant fact, but we must look unpleasant facts in the face. The nature of the medical man's work brings him constantly into contact with septic matter. There is no avoiding this. What we have to do is to take the precautions happily at our disposal to avoid the risk or reduce it to a minimum. The obstetrician, if he has much gynecological practice, is especially in danger of infecting his patient. He has, in constant vaginal examinations, to imbue his fingers with vaginal discharges, which may be of the utmost possible virulence, such as of uterine carcinoma. Many have infected themselves in this way through punctured wounds of the finger, and why not infect others?

If I dwell on unpleasant topics such as these, my only object is to secure a thorough appreciation of their danger and its avoidance. The nurse has often, and justly, too, the blame to bear. She is constantly handling the genital organs at all hours for many days. Many of the older class of nurses persistently set themselves against the antiseptic precautions, as "new fangled fads which they don't hold with." If they are positively ordered to carry them out, they are apt to do so in the most perfunctory way. The tips of the fingers are just dipped into the antiseptic lotion. A sponge is used to wipe the genitals and is put away unwashed, or most imperfectly washed, on a hot summer day. Quite recently I had occasion to use a catheter, and the nurse produced one belonging to her. I fished out of the eye a decomposing blood-clot, which had been lying there for days or weeks. Again, not long since, I saw a most intense case of septicæmia; the nurse answered me that she had been most careful, and yet I found an under sheet, unchanged for four days, saturated with lochia, on which the patient was lying. In a hundred unsuspected ways such as these, death may be conveyed to the patient. If, however, efficient antiseptics is to be carried out, the rules must be such as the nurse can understand, and not too complicated and troublesome to put into execution.

The following is a copy of the card given every nurse in attendance on cases under my charge:

Antiseptic Rules for Monthly Nurses.

1. Two bottles are supplied to each patient. One contains a solution of bichloride of mercury, of the strength of one part to one thousand of water, tinted with litmus (called the 1-1000 solution), the other carbolized oil (1-8.)

2. A small basin containing the 1-1000 solution must always stand by the bedside of the patient, and the nurse must thoroughly rinse her hands in it every time she touches the patient in the neighborhood of the genital organs, for washing or any other purpose, before or during labor, or for a week after delivery.

3. All sponges, vaginal and rectal pipes, catheters, etc., must be dipped in the 1-1000 solution before being used. The surface of slippers, bed-pans, etc., should also be sponged with it.

4. Vaginal pipes, enema-tubes, catheters, etc., should be smeared with the carbolized oil before use.

5. Unless express directions are given to the contrary, the vagina should be sponged twice daily after delivery with warm water, with a sufficient quantity of Cond's fluid dropped into it to give a pale pink color.

6. All soiled linen, diapers, etc., should be immediately removed from the bedroom.

N. B.—These rules are for the protection of the patient from the risk arising from accidental contamination of the hands and sponges. It is therefore hoped they will be faithfully and minutely adhered to.

There is nothing complex in these rules. The details may be varied considerably as to the form of antiseptic employed. It is the principle of antiseptics more than the details which is important. I prefer the bichloride of mercury to any other antiseptic, not only because of its acknowledged potency, but because it is bland and unirritating to the skin, and capable of being carried in a concentrated form, and the solution made at a moment's notice. Nurses will not use a carbolic lotion or will use it inefficiently, because of the tendency to injure the hands, while I have never known one to object to the mercurial solution. I do not recommend it for vaginal injections after labor, because of a few cases of mercurial poisoning that have been reported to follow its use in this way.

There are a few precautions to be used during the labor by the physician himself:

1. Before making any examination or using the antiseptic lotion, he should thoroughly cleanse his hands with soap and water, being specially careful about his

nails, under which septic matter may easily lurk.

2. At an early stage of the labor the vagina should be thoroughly syringed once with the antiseptic lotion, and the vulva sponged with it.

3. When the head is distending the perineum the external genitals should again be sponged with the solution.

4. Cold cream, lard, etc., should not be used for lubricating the fingers, but carbolized oil or vaseline employed instead.

5. When possible, sanitary towels should be used to receive the lochial discharges, in preference to diapers, as they may be burned when soiled. All risk from imperfectly cleansed diapers is thus avoided. I do not think these suggestions impose a grievous burden upon the practitioner who has the welfare of his patient at heart.

There are many other points on which I might dwell if time allowed. One which seems particularly important, is the duty of satisfying ourselves of the sanitary condition of the house in which our patient is to be. It is but seldom, however, that our opinion is asked on this point. Unfortunately the public believes it is the duty of the profession to cure disease when it arises, not to prevent it. Meddling with such matters beforehand would be too often considered an unjustifiable interference. I am fully convinced that if a careful sanitary inspection were instituted before parturition, a great step would be taken towards attaining the object of this paper, "The Prevention of Puerperal Fever."

The subject was farther discussed by DR. ROBERT BARNES, of London, who read a paper on this subject:

The Causes, Internal and External, of Puerperal Fever.

A clear understanding of the nature and causes of puerperal fever is the rational antecedent of a rational system of prevention. What is puerperal fever? What are its factors and constituents?

There is not one cause but a plexus of causes. Failure to comprehend this truth is especially conspicuous in the German works. By a short and arbitrary process of synthesis this school has formulated the dogma that puerperal fever is puerperal septicæmia, the result of septic infection from the genital canal, thus overlooking important constituent factors. Starting from the state of gestation we find it specially marked by exalted nervous and vascular

tension. An acute process of building up is going on.

Parturition puts to the supreme test every tissue, every function. We have the combined sources of altered blood: 1. That derived from gestation; 2. That arising during labor; 3. That arising from the disintegration of the superfluous tissues, built up during gestation. Labor completed, a process is started the very reverse of that which prevails in the gravida. The high vascular tension subsides, the tide turns, the blood is invaded by waste stuff which has to be cast out of the body. This is done mainly by the excreting glands, liver, kidney, skin, intestines, lungs—all of which are called upon for active work. They must discharge the waste stuff as fast as it is received into the circulation. If this waste stuff be not duly excreted it accumulates and acts as a fever-causing poison. Cases of thrombosis and phlegmasia dolens are mainly the expression of the loss of balance of disintegration and elimination.

This is the simplest, the fundamental form of puerperal fever, but it is the compound of three forms of altered blood: 1, the blood of the gravida; 2, the blood of the parturient; 3, the blood of the puerpera. This is purely auto-genetic. I call it endo-sepsis, because the conditions arise entirely within the patient's system.

Another group of symptoms which disturb the orderly course of the puerpera are influences which *retard the secretions and excretions*, as chills, malarious conditions, errors of diet (among which insufficient diet is one) and bad hygienic surroundings and emotions.

Meteorology controls these secretions largely, and I believe has no little effect on the frequency of puerperal fever. I show here a number of charts, the first of which shows, according to the Royal Meteorological Transactions, the general temperature and rain fall for 30 years—1844 to 1874. No. 2, shows the deaths from scarlatina, fevers, erysipelas and puerperal fevers for the same period. No. 3, shows the total births and deaths for the same period. The second series I have constructed on the same plan. It consists of the history for 10 years, 1875-1884, the months and weeks of each year being cast together. In the second series we get the curves for the following 10 years. The separation of 10 years can be compared with the preceding 30 years. The general similarity of the curves is remarkable; it affords strong evidence of the universal prevalence of the causes.

The tables exhibited show the relation of the seasons and atmospheric conditions to fevers, puerperal and others, and illustrate a law which has been widely recognized, namely, that zymotics are most fatal in the winter. This, I believe is true; the damp from the cellars, charged it may be with foul water, but noxious in any case, is sure to be sucked up into the house and seeks by preference the warmest spot. This is the lying-in room, the heat acting as a relative vacuum in the highly heated and poorly ventilated room. This source of danger is distinct from the ordinary drains or sewerage of the house; either may act alone, or they may act together, intensifying the danger.

This damp foul air drawn into the lying-in room may be contaminated with specific poisons, as of typhoid, scarlatina or of erysipelas; but the contamination is not necessary to work mischief in the puerpera. This evil, that the lying-in room is chiefly supplied by air from the lower regions in winter, need hardly be felt in summer, as fresh air is brought directly from the outside. Pressure then works against the up-current, pure air is gained, foul air is repelled. Here the author showed a model house—to prevent this suction of foul air. During the past winter, an unusually inclement one, I have been called to attend an unusual number of cases of child-bed fever. I rarely failed to find sufficient cause for the trouble in the sanitation. I would enforce emphatically the old rule to move the patient to another room, preferably the drawing-room, which is generally the healthiest, most airy in the house. Sewer gas, if not carrying zymotic germs, may cause fever. The poison, however, will be kept up. Hence, the advantage gained from moving the patient away from the influences of her surrounding.

As to decomposing matter in the genital tract, we should first close the gates against the entry of the enemy by securing firm contraction of the uterus, and prevent the suction action of the abdomen. The next step is to give ecbolics, as quinia, cinnamon, nux vomica, ergot and digitalis. Some combination of these medicines should be given in every labor. We should then eject the enemy, and prevent the gathering force by washing out the uterus. Uterine irrigation is especially useful in the auto-genetic forms, in which noxious matter is taken up from the genital tract. It is not frequently necessary in the hetero-genetic or zymotic forms.

The women of the laboring classes go through child-bearing more safely than their pampered and delicate sisters. It is because they are not subjected to and enfeebled by excessive cultivation of the emotional and intellectual elements. The daughter of luxury never knows a day's labor till she is taken in labor. While the woman of the working classes labors every day.

Lactation is evidence of glandular capacity. Failure to produce milk is presumptive evidence of glandular incapacity. Fever prevents or diminishes secretion; in some cases at least.

Fever declares itself because the glands cannot do their duty.

From what has been said, it follows that to ensure the fullest security to the puerperal woman, to put her in the best position to go through the transition from the puerperal to the ordinary state, we must do what we can to keep every organ including the glandular system in good working order; and to guard against all known agencies which may disturb the healthy action of the organs.

The relations of Meteorology to Puerperal Fever is a point to which I wish to call especial attention. We see by the tables that puerperal fever like other fevers prevails most fatally in winter. To what extent can we control the pernicious influences of winter weather? Domestic meteorology is greatly under our control. We must inquire what are the external conditions which favor excretion. The excretory force of the lungs is increased in value in the puerpera. Under ordinary conditions in the non-pregnant they give off watery vapor, carbonic acid, sometimes ammonia and a minute quantity of organic matter. It is certain that the capacity of the lungs increases after labor, so it is probable the quantity of carbonic acid exhaled is increased, and it is certain that the exhalations of organic matter increase. The "gravis odor puerperii" is partly due to this increase. In some cases, those verging closely on endosepsis, the lochial discharge is absorbed. In these I have noted a sallow aspect and a degree of febridity, and I have taken this as an indication for irrigating the cavity of the uterus.

To get rid of the excess of aqueous vapors of carbonic acid, and organic excreta by the lungs and skin, a constant supply of pure air is required. It must be dry and comparatively rare. There are two principal modes by which gaseous matter including germs of bacteria, are carried: first, by diffusions; second, by currents of air. Active diffusions

are especially valuable so long as they bring nothing noxious to the patient; but if foul matter comes with the air it will tell against the case; hence the great importance of a supply of pure air, and the removal of all impediment to free circulation. I am disposed to believe the most injurious of all meteorological conditions is damp, in the forms of saturated air, fog, and mist. Wind, rain, and sun are the great purifiers of the atmosphere; movement of the air promotes diffusion, sunshine works chemical changes, and the rain scours or washes away impurities. All this of course is familiar knowledge, but it is not superfluous to ask, if it is fairly applied to the regulation of the sick room? Let us consider how far we may bring the meteorology of the bed-room to the conditions of healthy external meteorology; first, let the lying-in chamber face the south; second, to combat external damp, a fire is best in an open fire-place, the open grate serving as a ventilator to carry off impurities. Among the abominations of self-styled sanitary engineers, I feel called upon to denounce heating by hot water pipes. They are too often effective means for the culture and diffusion of noxious germs. It is possible also to wash the air admitted by a Dobin's tube, by a shower of water falling into the tubes.

The modification of the air by chemical agents, with the mechanical addition of vapors and gases possessing medical virtues, has many recommendations.

In the early morning hours between 2 and 4 o'clock is the time when the wind is the lowest and the meteorological conditions the worst. At this time the ventilation of the room should be attended to with greater care than usual.

All precautions resolve themselves into one word, cleanliness. All antiseptic precautions are but a part of the general scheme.

The meteorological conditions are of primary importance though I am far from underestimating other causes.

Whilst protecting the citadel from the foe without we should take care that mutiny does not break out within.

JOHN W. BYERS, A. M., M. D., Belfast, continued the subject by reading a paper on the

Prevention of Puerperal Fever in Private Practice.

After giving some statistics showing the great mortality of puerperal fever, the writer said it was impossible to take measures for its prevention until we had clear ideas as to its causation. He discussed the various views and gave his reasons for believing it

to be blood poisoning analogous to septicæmia met with in surgical practice. Taking this view, he believed there were three sources by which the poison might be introduced into the system of a lying-in woman:

- 1st. Sewer gas, as in unhealthy homes.
- 2nd. The nurse.
- 3rd. The accoucheur.

Under the first head he recommended the inspection of a house before the confinement took place to see if it was in a proper sanitary condition. He gave rules for the guidance of the practitioner and nurse. He advised the strictest cleanliness, thorough washing of the hands in an antiseptic solution (1-1000) bichloride of mercury, few examinations, a proper and careful management of the third stage, the keeping of the patient on her back for a time after confinement, and antiseptic douches.

He drew attention to the cases in which a decomposing blood clot or placenta might be the source of the disease, but believed that even in these cases the decomposing mass in the uterus only acted as a nidus in which the poison from without found a suitable soil.

He discussed the question of how a physician should act with reference to obstetric practice, if he came across cases of scarlatina or foul surgical wounds, and said he believed by baths, changing the clothes, and strict antiseptic washings, he need have no fear in attending a patient during confinement. He said if those who attended women in labor would act as if each one were likely to develop septicæmia, they would take thorough antiseptic precautions and thus such cases would be reduced to a minimum.

The whole essence of the prevention of puerperal fever was:

1. To prevent the poison entering the system.
2. To destroy the poison if it got into the genital tract of a patient, before it entered her tissues and blood.

A paper by DR. GRIGG of Queen Charlotte's Lying in Hospital, London, on this general subject, was read by title.

DR. ROBERT BARNES, of London, said that we all agree in what Dr. Playfair has said, and it is of extreme value to us to have it put so well. It will be well for us to follow out antiseptis; but antiseptis is not the whole prevention of puerperal fever. I do not think with Dr. Playfair that it is the same as surgical fever; but that it may be caused by cold, chill, exposure, fever, meteorological conditions or accidental causes. This fever is far more common in winter than in summer.

There is something before septicæmia. There is a puerperal constitution which makes the poison doubly dangerous. I hope Dr. Playfair will go a little farther back and look a little at the patient.

DR. GEORGE H. KIDD, of Dublin, considered further the question of the nature of septicæmia. Dr. Burdon Sanderson has said there was a time when we were obliged to fight with all our might to make people believe there was such a thing as septicæmia. This is not the trouble now. The danger is that we put too much stress on antiseptis. He believes that attention to the patient previous to labor has much to do towards preventing the septicæmia. Dr. Collins, when master of the Rotunda Hospital, delivered eleven thousand women in that institution in four years and had not one case of septicæmic fever. We must not overlook the natural history of the disease, the fact that it comes in epidemic waves.

DR. LOMBE ATTHILL, of Dublin, said he was a firm believer in septicæmia. The term puerperal fever he abhorred. It is caused by septicæmia. I was the first master in the Rotunda Hospital to require antiseptic precaution which was then very imperfect. I had to undergo great opposition. Especially was this so with the nurses. It was indeed an effort to get them to part with their old black dirty dresses and put on the uniform. They thought that to be compelled to wear such dresses as they were in winter was nonsense. I consider a relaxed condition of the uterus to be a common cause of septicæmia. I well remember one patient who came into the Rotunda in labor. No physician was present at the time, but the nurse saw there was something the matter with the patient and put her in a private ward separate from the other patients. I was soon called and found the patient to be suffering with erysipelas. She could not be put out of the house in labor, but after delivery she was sent to another place, only remaining in the hospital fifteen hours. There had been no case of puerperal fever for months before, yet there was one before twenty-one hours, and this was followed by several others, then the disease gradually disappeared. I think, however, these cases were due to atmospheric conditions, and not to the presence of the woman in the hospital. I think contamination in that case possible under the conditions. I hardly believe that the preliminary treatment of puerperal fever will prevent puerperal fever in many cases. I do not believe ergot given in a single dose will produce any effect. It should be given frequently.

DR. M. T. MALONY, Arklow, Ireland, said that in his city of six thousand inhabitants there had been an epidemic of scarlet fever for six months. During this time there was no case of puerperal fever and no approach to one. The scarlet fever was of a mild type, yet some cases were quite malignant. We had many cases of sore throat, some of them malignant, and some tonsillitis, &c. The town is the most unsanitary place on earth. As medical officer, I attended the most of the cases of labor. I used no antiseptics, except on my forceps.

DR. C. H. F. ROUTH, of London, thought that women in an unhappy state of mind, such, for instance as had been seduced, as has been shown by Dr. Barnes, were much more likely to suffer from puerperal fever.

DR. JOHN W. BYERS, of Belfast, was a thorough believer in the septicæmic view of puerperal fever. How can the gentleman, maintaining the views of other causes of puerperal fever, explain the results of antiseptics in hospitals? Our nurses should be firm believers in antiseptics. Opinion is now, I think, going in the direction that the number of cases which are autogenetic are diminishing. The doctor then quoted from a paper by Dr. E. G. Zinke, of Cincinnati, read before the American Medical Association in 1887, in which the question of "How soon after exposure to infection can you attend a woman in labor?" was discussed, and the opinions of prominent authorities quoted. These opinions were at great variance. It was a question he would wish answered.

DR. SAMUEL SLOAN, of Glasgow, said that antiseptics in the hospital in Glasgow had reduced the mortality much. They could not do without antiseptics. We should look more to antiseptic measures than we do. He thought close rooms in winter were more productive of puerperal fever than chill.

DR. MOORMCY, of Edinburgh, thought the plan to stamp out puerperal septicæmia was Eutopian. How can we stamp out atmospheric conditions, lochial discharges, etc.? The patient should be prepared before-hand. She should be given the chloride of iron, quinine, potash, etc. Ergot in small doses before labor is innocuous and acts beneficially. The prevention of puerperal septicæmia is the function of the nurse, more than of the doctor. It is not at all above the dignity of the obstetrician to look after the nurse. He closed by recommending uterine injections.

MR. LAWSON TAIT, with Lombe Atthill, *abhorred the name of puerperal fever.* The

practitioners in his neighborhood had been giving him the opportunity to open the abdomen in cases of puerperal septicæmia, which had been followed by good results. There are two kinds: one disease is systemic, and medicine and surgery are powerless; the other is local, and the patient can be saved. He had recently been called into the coroner's court to testify in a case where sixteen patients were taken with puerperal fever in the practice of one man, all of whom died. He inquired, and found that the most elaborate antiseptic preparations had been made and carried out. He did not inquire too closely, fearing to find out too much; but after the trial, remembering that all the cases of puerperal septicæmia had been forceps cases, he asked him what precautions he had taken with his forceps. He replied, none. There was the whole secret.

DR. H. CAMERON, of Glasgow, had seen five cases of puerperal septicæmia in one man's practice. He found that he had not been in the habit of disinfecting his forceps. He advised him to disinfect his forceps and burn his leather bag.

DR. W. H. HUMISTON, Cleveland, Ohio, said: If, as one gentleman has stated, puerperal fever is an epidemic disease, and occurs in waves without any assignable cause, why does it not now occur in the lying-in hospitals at Dresden, Prague, and Vienna? In these very same institutions, prior to the adoption of strict antiseptic precautions, the mortality from puerperal septicæmia was appalling, ranging from 10 to 18 per 100. It has been my privilege to visit these institutions, and study and observe their methods of conducting obstetrical cases. They are most careful, and insist on the highest degree of cleanliness obtainable, by frequent washing of hands and instruments with soap and water and antiseptic solutions. When Prof. Leopold took charge of the Dresden Lying-in Hospital, the mortality was 18 per cent.; by strict antiseptic precautions it was brought down to *nil*, and has so remained for several years, not a case occurring within its walls.

One gentleman has asked how soon, after coming in contact with septic material, is a physician justified in attending a case of obstetrics? I answer, at once, allowing time for change of clothes and thorough washing with trustworthy antiseptic solutions.

In Carl Brown's wards in the lying-in department of the general hospital at Vienna, the assistant has charge of the wards, and takes personal charge of all complicated

cases. At the same time he is daily giving operative courses upon the cadaver to students and practitioners, and I have seen him summoned from the operating table in the pathological building to make a forceps delivery. He would remove his protective coat and go through the most careful washings of the arms and hands. I never saw septic trouble arise in cases so managed. One important point which is original, and I hope will be found trustworthy by you in your future practice, is the indication that the specific gravity of the urine gives in foreshadowing coming trouble. If before and soon after delivery the specific gravity of the urine is markedly below 1020, look out for breakers ahead; for, with the great amount of effete matter to be carried out of the system, the urine, if the elimination be sufficient, will be of high specific gravity.

DR. R. Y. DILL, of Belfast, advised the washing of the hands under a tap instead of scrubbing dirt into them with a brush. Mind your nails. Always give two or three doses of ergot during the last two or three severe pains of labor. The mechanical arrangement of the beds should be such that the foot can be elevated in case of flooding, and the head elevated to assist drainage of clots.

DR. CORLEY, of Cork, favored the semi-erect position, but did not favor the immediate suture of the perineum.

DR. WALLACE, of Birmingham, favored antiseptics, but favored still more absolute cleanliness. He dips his forceps into boiling water, and nothing further is necessary. He cleans out the uterus in the early part of the disease, and swabs it out with the tincture of iodine. As to abdominal section, when you have absolute purulent septicæmia, nothing helps. When local septicæmia, help can be obtained.

DR. SHAW had practiced in London for 13 years, and had 1900 cases of labor. He never washed out a vagina, disinfected his forceps, nor lost a case from puerperal septicæmia.

DR. A. V. MACAN, of Dublin, said that we are all agreed that sepsis is a great danger after delivery. What is the relative danger of sepsis and other causes? If antiseptics reduce the cases so enormously, the great majority must be caused by sepsis. The remainder we will present to those who think there are other causes. It is a small present. Even in the heterogenetic, sepsis must be introduced. I must say that allowing a nurse to go out to follow her calling after a three week's training, as is the case in London,

is a disgrace to civilization. Here in the Rotunda we think six months little enough.

DR. PLAYFAIR, in closing the discussion, said: The words puerperal fever were not used in the paper, yet that term was heard again and again in the discussion. Cold and chill may produce a puerperal disease, but not puerperal septicæmia. No one is more fully possessed than I with the idea of preparing a patient against puerperal septicæmia. As I said, my allotted time was far too brief to allow me to go over the whole ground. I must omit something. I think there never was an epidemic of puerperal septicæmia. It does not come in that way. It is totally different from cholera and that class of diseases. This is a most dangerous theory. Puerperal septicæmia may be introduced through the atmosphere. The statement of Dr. Humiston is one of the most remarkable statements I ever heard.

DR. M. Q. MCCALLAHAN, of Brailsford, read a paper on "A Month's Abdominal Sections," by Mr. Lawson Tait. This consisted of a brief report of 35 abdominal sections, of course all recovering, some of them almost snatched from the other world. Several were performed for septicæmia.

MR. TAIT who was present, said that the reports just read would show how he selected his cases. This cry about the selection of cases is an absolute falsehood. I care not who says it. One case reported here was one I would certainly have been excused from operating on. The woman was brought in in a state of collapse, almost dead. I had done 300 laparotomies with but a few deaths and I did not care, I assure you, to add another. I confess it was a temptation to refuse but I thought I must give the woman a chance for her life, slight as it may be. The result was wonderful. Suppose some one of our "tramp visitors" had come along and seen this case; he would have gone away saying, Lawson Tait is the most reckless operator I ever saw.

DR. ROBERT BARNES, of London, expressed unqualified admiration of Mr. Tait and his results. He thought the surgery of the abdomen and of the brain were epochs in surgery. He was glad to know that they were British productions and that we were not indebted for them to the Germans.

DR. W. H. HUMISTON, of Cleveland, O., said that he was one of these "tramp visitors" who was excluded by Mr. Tait. He had heard Mr. Tait abused and called a liar in Germany, but it was done by those "tramp visitors," scamps and scalawags, who went once or twice and then went away to criticize.

If you want to study a man's methods go and stay long enough to know them.

Mr. Tait: the "tramp" does mischief in more ways than one and I'll have nothing more to do with him. He is doing mischief on the other side of the Atlantic. There are two kinds of doctors in America as well as in England. Some know something, others do not. I have had doctors come from America, bring their wives and families and stay six

months. I taught them all I could. Others came once or twice, went away, and knew more than those who had tarried six months.

No case of puerperal peritonitis ought to be left to die without the abdomen being opened, and I believe the day will come when we will make a large number of operations in the median line for hernia.

Several other speeches laudatory of Mr. Tait and his methods were made.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Lime Treatment of Local Tuberculosis.

Senger (*Deutsche med. Wochenschrift*, No. 31), has made a critical study of the method of treating tubercular joint affections practiced by Kolischer. After speaking of the uncertain and often unfortunate results following the ordinary treatment of such cases, and the skepticism which one naturally bears toward new therapeutic attempts, he says that the statements of Kolischer and the endorsement of Prof. Albert seem to leave no doubt as to the great value of this method. Prof. Albert said that few facts made such an impression on him as the cases treated by Kolischer. As the result of careful observation he had to admit that the method furnished a noteworthy therapeutic effect and could be warmly recommended for further trials. The results were surprising, not only on account of the rapid healing, but also on account of the complete and free motion in the diseased joints.

Kolischer proceeded on the assumption that it might be possible for the fungus joint affection to undergo a calcification similar to that occurring in tubercles of the lung. In connection with Dr. Freund (assistant in the physiological laboratory) he made experiments with acid calcium phosphate, and found that its effect was much increased when the solution contained an excess of free phosphoric acid. Kolischer distinguishes two kinds of fungus inflammations: First, those not yet gone on to the formation of fistulæ; second, those already fistulous. In the treatment of the first kind, Kolischer proceeds as follows: A sublimate dressing is applied for twenty-four hours. The part is then washed with soap and water and irrigated with a one per cent. sublimate solution. Then the solution described below is injected. The hypodermic syringe is

of hard rubber, with a platinized needle (steel being acted on by the solution). The syringe is kept in five per cent. solution of carbolic acid. Injections must be made in different parts of the tumor, part of the contents of the syringe being expelled each time. The "fungus" must be entirely permeated by the solution, and give a peculiar juicy feeling, while the parts not injected are depressed and elastic.

The needle must be inserted as far as possible, even into the softened bone. The injections are very painful, and after a few hours severe pain ensues, for which morphia hypodermically is recommended. An antiseptic dressing is applied. High temperature, lasting 17-24 hours, follows, and the inflammatory reaction lasts 5-6 days. After this time the joint is put in a starch dressing, which is renewed as often as it becomes loose. After from three to six weeks more the swelling has disappeared, there is a limy hardness perceptible, but no pain. Massage and passive motion are begun. Malpositions can be corrected by the dressing in the latter days of the reaction.

The second class of cases is treated by widening the opening, tamponing the cavity with gauze soaked in the solution (No. 2), and covering all with a sublimate dressing. The tampon is renewed every two days. As soon as healthy granulations appear iodoform and arg. nit. can be used. Caries of the bone is treated in a similar way.

Cold abscesses are opened freely and packed without being scraped out. Tubercular fistulæ in ano are treated similarly. Attempts to treat enlarged glands were too few to be considered as to their result.

Kolischer has treated more than 200 such cases, with striking results. Three cases were demonstrated to the Vienna Medical Society, with casts showing the affected parts before treatment. Two of these were

cured tuberculosis of the elbow joint. Another was a boy of four years, who six weeks before was admitted to the clinic with the right knee ankylosed in an angular position, with intense pain on motion, etc. Finally a case of tuberculosis of the wrist joint was shown. A week before this had been swollen, with lateral movability in the joint and metacarpal bones. At the demonstration the hand had almost normal contours, the parts formerly swollen were hard and bony, there was no pain, and active motion of the fingers was possible.

Freund originated the following formulæ after a study of the blood of tubercular subjects, though the manner of the investigation is not given:

1. R Calc. phosph. neutr. gr. lxxv
Aq. destill. ʒj ʒ ivss
Then add: Acid. phosph. q. s. to make a perfect solution. Filter and add
Acid. phosph. dil. ʒ ix
Aq. dest. q. s. ad. f ʒ iij ʒ j
S.—For injection.

2. R Calc. phosph. neutr. f ʒ iss
Aq. destill. O j
Then add: Acid. phosph. q. s. to make a perfect solution; filter and add
Acid. phosph. dilut. f ʒ ii-iv
Aq. destill. q. s. ad. O j
S.—For impregnating gauze.

The fluid for injecting is sterilized, which causes a precipitate. This, however, is redissolved on cooling. For the gauze-solution 1 per cent. of free phosphoric acid suffices in mild cases, 2 per cent. for very chronic cases. The dissolved acid calcium phosphate solution amounts to 6.5 per cent.

Senger says that on account of the great importance of the subject he has given it so much space, and especially in consequence of Albert's favorable criticism. From the result of the lime water treatment of phthisis pulmonalis he confesses disbelief in the probability of great success, but admits that in local tuberculosis the conditions are not exactly parallel, and the method of Kolischer need not be discarded for a priori reasons. His doubt has been much increased by the latest communication of Kolischer, in which, from a study of 500 cases, the latter admits that in severe tubercles of bones, necrosis, tubercular ulcers and glands, the lime method is of little value. But in children, especially in regard to the restoration of function, the results are brilliant and imposing. Even in severe bone diseases a certain cure is attained, though in rare cases even in children the results are negative. In older persons the results are still more unfavorable. Extensive necrosis Kolischer recom-

mends to be treated by chiselling and then tamponing with the lime gauze. This very fact is suggestive, inasmuch as it is abandoning the idea of cure by medication. Even if the numerous fungous arthritides could be cured by Kolischer's method the therapeutic advance would be great. Unfortunately this is doubtful, because he himself admits the difficulty of curing bone tuberculosis, and the most arthritides depend on or originate from primary foci in the bones. It would be encouraging if this doubt were caused by an imperfect separation of bone and joint diseases on the part of Kolischer, and not by an imperfection in the method.

It is very desirable that the lime treatment should be studied by other investigators.

Spontaneous Expulsion of a Foreign Body after staying in the Eye for Five Months. Perfect Sight Restored.

L. Debierre gives the following account of this most interesting case:

On November 5, 1886, a child eight and a half years old was taken by his father to the clinic of M. Meyer for an injury of the left eye, which had occurred two days before. It seems, from the father's account, that the child was striking fulminating caps with a hammer, when one exploded and wounded the left eye, causing at the same time a jet of blood to spurt some distance. The child was hurriedly taken home and a doctor immediately summoned. The latter applied compresses to the eye and then a protecting bandage.

At the first examination at the clinic (two days after the accident) there was marked œdema of both left eyelids. The skin was intact, the wounding body having struck the ball of the eye directly at its supero-external part, eight to ten millimetres behind the sclero-corneal margin. At this level there was a very pronounced chemosis, divided into two by a contraction of conjunctival tissue indicating the point of entrance of the vulnerating body. A little pericorneal injection in the internal part of the corneal border; anterior chamber intact; pupil with maximum dilatation; crystalline lens seemingly transparent; vision $\frac{1}{10}$ of normal. The field of vision taken at the perimeter showed a very marked limitation at the inferior part which almost amounted to complete failure. Ophthalmoscopic examination proved the presence of a large effusion of blood occupying the superior portion of the retina and extending nearly to the superior border of the optic disc. At this level the retina seemed lifted up and even loosened from its attachments.

An endeavor was made under chloroform to find and remove the body, but without

success. The child was kept under observation in bed for five days, and as there were no bad effects from the exploration, another ophthalmoscopic examination was made; at which time the hemorrhage which had occupied the superior part of the fundus of the eye had to a great extent been absorbed, and one could see below and beyond the disc a large ecchymotic spot at the inferior part of which the presence was established of a black body which Meyer supposed to be the foreign body. The retina was lifted up throughout the superno-external region. The rest of the eye was sound, the vitreous and chryalline lens perfectly clear, and vision had increased to $\frac{1}{3}$ normal. In this condition, the child suffering no pain, he was directed to return home; the father, however, was admonished that at the least painful accident arising in one of the eyes he should at once bring the boy back.

The patient was then lost to sight until March 16th, 1887, when he returned because of pain and of a sensation of a foreign body in the upper part of the injured eye. On lifting the upper lid, the point of entrance of the foreign body was seen as a circumscribed swelling about one centimeter in diameter. In the middle of this reddened swelling was a more depressed point, which seemed open, and, on touching it with a metallic sound, there was a certain resistance. The rest of the eye presented no alteration; vision normal, with the exception of slight hypermetropic astigmatism. Field of vision normal, except below and within, where there was limitation, which for colors went nearly to the point of fixation.

The pupil was dilated to the maximum, and at the ophthalmoscopic examination there was recognized in the superno-external part, at a distance of a papillary diameter and a half from the entrance of the optic nerve, an alteration of the fundus of the eye having a horizontal diameter of twice that of the disc, and a vertical diameter of one and a half times that of the optic disc, of irregular form, grayish color, and bordered irregularly with pigment. The centre of this spot served as the point of origin of a pedicle in shape like a large tent, and having a diameter equal to that of the optic disc. This pedicle begins to grow rapidly smaller, and in the shape of a cylindrical tube with very thin and transparent walls crosses the vitreous, and growing slightly larger again, stretches to the point of origin of the foreign body. At this level the tube becomes absolutely black. Throughout the length of the inferior border of this membranous tube are found

isolated particles of pigment forming a regular track, so that it shows the annexed pattern, of which we have been able to easily take a picture. All the rest of the retina is perfectly normal, and so are both the vitreous and chryalline lens.

After putting the child to sleep with chloroform, M. Meyer enlarged with a slight cut of the scissors the conjunctival wound and easily seized with small forceps the extremity of the foreign body and withdrew it. The cap was rectangular in shape, $6\frac{1}{2}$ mm. long by $1\frac{1}{2}$ m.m., weighing about $1\frac{1}{2}$ cgm.

The sequel of this slight operation being good, the child was sent home, its vision being normal and continuing so when seen some days later, but still presenting the curious alteration at the fundus of the eye.

To sum up: There had been the penetration of a metallic body through the external wall of the sclerotic and vitreous and lodgment within the deep membranes of the eye; then five months afterwards a reappearance of the foreign body at its point of entrance.

After discussing and rejecting the possible supposition that two foreign bodies had entered the eye through one wound, or that one body had become divided into two at its point of entrance, the author maintains that but one foreign body entered the eye; that this passed to the fundus and then gradually worked itself back to the point of entrance. In support of this position he calls attention to the pigmented track of the tube, and also to the experimental researches of Leber upon foreign bodies artificially introduced into the eyes of animals. — *Revue Générale d'Ophthalmologie*, June 30, 1887.

BOOK REVIEWS.

Sexual Impotence in the Male and Female. By William A. Hammond, M. D., etc., New York. Published by Geo. S. Davis, Detroit, 1887.

This new edition of a well-known book contains a chapter on impotence in the female that renders the book complete in its way. The book is divided into four sections, and treats of—

- I. Absence of sexual desire.
- II. Absence of power of erection, and of consequent intromission.
- III. Absence of the power of ejaculating the seminal fluid into the vagina.
- IV. Absence of the ability to experience pleasure during the act of copulation and at the time of the emission of the semen.

Three corresponding sections are devoted to impotence in the female.

REVIEWS OF PAMPHLETS.

—"Practical Thoughts for Physicians" is the title of a paper by Dr. G. W. H. Kemper, of Muncie, Indiana, which was read before the Indiana State Medical Society, May 10, 1887. The paper shows Dr. Kemper to be a clear-headed thinker as well as a good man, a happy combination that cannot occur too frequently.

—A very interesting and comprehensive description of "Intubation of the Larynx," is contained in a monograph by E. Fletcher Ingals, M. D., of Chicago. It is a reprint of two articles upon this subject that appeared in the *New York Medical Journal*, July 2 and 9. The author states that he has reports of 514 cases, in 134 of which, or 26.7-100 per cent., the patients recovered. He advocates the claims of this operation for preference over tracheotomy, and remarks, that while it cannot always take the place of tracheotomy, it has much to recommend it in the majority of cases.

—Dr. C. W. Moore, of San Francisco, Cal., in his "Review of the Advances of Surgery, Medicine and Pharmacy in the last Forty Years," notes a number of things in which there has been improvement since he began practice forty years ago. A few of these are thoracentesis, cerebral localization, systematic examination of the urine, hypodermic medication, treatment of vesicovaginal fistula, treatment of aneurism by

digital compression, experimental therapeutics, etc.

It is a very hopeful sign when an old practitioner sees not only what has been gained in the way of increased knowledge, but looks with bright anticipations to the future.

—We have received a reprint of a paper on "Suppurative Inflammation of the Antrum," read in the section on Otology, etc., of the American Medical Association, by E. Fletcher Ingals, A. M., M. D., of Chicago. The author recommends hot fomentations, local blood-letting and saline purgatives in acute inflammation of the antrum. Free exit must be given to the pus, preferably through a decayed tooth. If the teeth are all sound, the author thinks it advisable to draw the first molar. It is better to make a comparatively large opening, which is best done with a bone-drill. As a subsequent wash, the author recommends peroxide of hydrogen, 3ss—3j to f3j.

The paper is to be commended for its clearness and avoidance of unnecessary technicalities.

—"Intelligence in the Van; the Beginning of the Beginning and the End of the End," is the title of an essay by Dr. Horace Dobell, of London. The writer says he made in 1861 in his "Notes for Future Work," this memorandum: "Is not the difference between what we call instinctive action and intelligent action simply that, in one case, the development of the necessary faculties and machinery is perfected before birth, and in the other after birth; and does not careful observation detect that even instinct is, in a small degree, further perfected after birth, just as intelligence is so perfected, in a larger degree?" Until 1886 he was unable to develop this thought. As the result of cogitations since then, the writer thinks "*the position of the material universe is intermediate between Potentia in its primordial state of diffusion and its final state of individualization.*" From the birth of the first atom of matter, through all the wondrous forms in which it is presented to the senses of conscious beings, including those beings themselves, it is but the medium for the attainment of the eternal ultimum of man, "when the spirit shall return unto the God who gave it."

It is but seldom that a physician in active practice can devote time to a study of the higher problems of metaphysics, and when he does, his point of view is generally materialistic.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record.	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,000 copies.

SPECIAL NOTICE TO SUBSCRIBERS.

Subscribers to the MEDICAL AND SURGICAL REPORTER, who have remitted payments to the former editor, and who do not find upon the wrapper of their journal a correct statement of the time up to which they have paid, are requested to notify the present publishers as soon as convenient.

THE AUTUMNAL FEVERS.

The advent of the season during which these fevers prevail makes a discussion of the modes of distinguishing the various forms of them both appropriate and profitable. The most important paper recently presented to the profession was read before the meeting of The Association of American Physicians in Washington, by Atkinson, of Baltimore. The series of cases which the author recorded were undoubted cases of typhoid fever, which presented the single feature of continued fever alone. The specific symptoms were absent, and yet we take it the association agreed with him fully that no other diagnosis than typhoid fever would have been warranted.

This fever, with the various forms of malarial fever and the simple continued, form

what we have to do with in this climate. Of the latter fever, Guit ras very happily named one variety, more common to the south and due to the heat, a continued thermic fever.

Of the differential diagnosis between malarial fevers, of remittent and continued type, and typhoid fever, much was said in the discussion. The usual characters of each are well-known and we therefore take occasion to refer especially to some recent methods of distinguishing them. This paper limits itself to an examination of the blood and the urine.

In malarial subjects the detection of the pigmented hyaline bodies, the crescentic bodies and the flagelliform microbe of Laveran in the blood, is all that is sufficient. A microscope with an amplitude of 800 to 1200 diameters, the former for the bodies, the latter for the germ is all that is necessary in the way of instruments. On the other hand in typhoid fever, examination of a drop of blood, previously stained, will reveal its characteristic micrococci while by the now well-known methods of culture, the features of this microbe are more readily distinguished.

Dr. Jacobi referred to the Diazon test for the recognition of typhoid fever. We much regret having to take issue with the Professor. We must say we thus far have found it of no avail, and we learn direct from Leyden of Berlin that the characteristic purplish discoloration of the urine, said by Dr. Jacobi to occur, in this test, in typhoid fever and tuberculosis only, is considered by the German professor liable to occur in all cases in which there has been much exhaustion. The absolute, the final test of the two varieties of fever, therefore, is the recognition of their specific cause in the blood.

A DIABETIC PATIENT IN SEARCH OF HEALTH.

Jules Cyr, who has written much and well on the subject of hepatic and renal diseases, has published a lively little brochure with the title: "Impressions and adventures of a diabetic," in which the experience of his patient with a variety of doctors and treatments is given. One of the most amusing

chapters, "La Médecine de Precision," is a good take-off on much that passes for scientific medicine, although the real counterpart of Cyr's "Polyclinic Institute," it might be difficult to find. Possibly the author aims the shafts of his satire at certain tendencies of the present day, rather than at any actual system of medical practice.

In the course of his travels, Sir Archibald Heartstone, the hero of the narrative, arrives at Artzburg-sur-l'Ammer, a university city *par excellence*, with its one hundred and fifty ordinary professors, twenty-five extraordinary, and a very respectable number of *privat doctenten*. As for the number of pupils, it scarcely exceeded by fifty the whole number of teachers. Here was the famous Institut Polyclinique, with professor Von Humbug at the head; this institute Sir Archibald proposed to enter to be treated for his malady.

At the office of the institute he was required to pay for a week's board and treatment in advance, and sign a declaration bequeathing in the event of his death his body to the institute for purposes of autopsy. Before being introduced to the supreme medical authority of the institution for final judgment concerning his case, and suitable treatment, he must first be examined by a corps of resident experts. First came the professor of etiology, who after an exhaustive inquiry into the antecedents of the patient—his father had had a fall on the head, and he honestly had suffered a similar disaster; and his mother (a nervous invalid) had died from some hepatic trouble—formulated a provisional diagnosis: "*diabetes of a traumatic, hepatic, nervous, diathetic character.*" Then came three long hours of ordeal with the expert onsymptomatology, who examined the thoracic regions with all the most modern apparatus of diagnosis, the cardiograph, the pneumograph, etc.; applied the sphygmograph to the wrist, then auscultated and percussed the chest, then finally tested the acuteness of the several senses and general sensibility by appropriate implements. Tired with this exhaustive examination, he was in

poor trim for the visit of the urinologist, who examined his urine quantitatively, qualitatively, and microscopically, confirming the diagnosis of the etiologist, and left him to the charge of the expert in therapeutics, who enters to take notes as to the various treatments which he had undergone, and the effects experienced therefrom. Finally, the arch-professor himself comes upon the scene, with the inevitable spectacles, gold-headed cane and bald head, escorted by three resident physicians, one *privat doctent* and two pupils. With exemplary gravity the findings of the several expert inquisitors were summed up in a few fitting phrases, and the medicinal treatment was comprehended in the one word *theriacum*, a very ancient and composite electuary whose principal ingredient is opium. Sir Archibald Heartstone thought this a most lame and impotent conclusion of so much scientific parade and flourish.

During his stay in Paris, our diabetic patient consulted a venerable physician, in whose description as given, it is easy to recognize the late Professor Bouchardet. Under the title of "An Original Consultation," Cyr gives the routine of daily exercises with bill of fare prescribed for his patient for one week. The diet table consisting of half a dozen or so, well chosen articles, was such as only a consummate connoisseur could write, and only a cook specially selected for the particular occasion could fill; it was beyond the capacity of any public restaurant. The exercises were to consist in digging the earth and removing the soil with a wheelbarrow, in a certain area of garden which had to be bought for the purpose; in marching for hours with a company of infantry; in several times making the ascent of the towers of Notre Dame, and in walking around Paris by the boulevards in the suburbs. It is not surprising that in attempting to comply with these requirements Cyr's patient found the road to health almost as arduous and beset with difficulties as did the hero of ancient fable the return from the cloud-encompassed regions of Tartarus; *sed revocare gradum, hic labor, hoc opus est.*

THE INTERNATIONAL MEDICAL CONGRESS.

Next week one of the most important events in the medical history of our country occurs: the meeting of the International Medical Congress, at Washington. There will then assemble in the Nation's capital two or three thousand members of the profession from all parts of the United States, and Canada; with hundreds of eminent physicians, surgeons, and obstetricians from abroad. Washington has rarely known a more august and learned congregation of eminent professional men than that which will honor it during the first week in September, 1887.

The MEDICAL AND SURGICAL REPORTER desires not only to wish the Congress great success, but also to give hearty welcome to the foreign members of the profession, who have not found the sea too wide or its perils too great, but have come to our land with fraternal love and sympathy, and with lessons of instruction in the noblest of arts and the best of sciences. May their brief visit be not less happy to them, than it will be both happy and useful to those who rejoice in their coming, and may its memories be perpetual pleasure without any admixture of bitterness or of sorrow.

NOTES AND COMMENTS.

MODERN TREATMENT OF COMMON DISEASES.

Bronchial Catarrh.

The following prescriptions are taken from Ewald's *Handbuch der allg. und Spec. Arzneiverordnungslehre* (Berlin, 1887).

- R Ammoniac.....gr. cxliiss
Aceti scillæ.....gr. ccxxv
Aq. fœniculi.....f3 vj f3 ij

Cannabis Indica in Diarrhœa.

Frederick F. Bond, M.D., and B. E. Ed-
 wards, M. B., give the following resumé of
 the treatment of diarrhœa in India, by can-
 nabis Indica: Dr. S. J. Rennie, Cawnpore,
 in the *Indian Medical Gazette* for December,
 1886, calls attention to the value of Canna-
 bis Indica in the treatment of dysentery.
 We wish to draw attention to its value in a
 similar condition, namely diarrhœa; espec-
 ially in the type known as summer diarrhœa
 or English cholera. Attention was drawn to
 it in this connection by Dr. Turner of the
 Holloway Dispensary, in the *Lancet* (vol ii.
 1866, p. 536: he says, "In ordinary diar-
 rhœa," (referring to summer diarrhœa pre-
 sumably) "the formula" (mentioned in a
 previous part of his letter as very valuable in
 cholera, namely

R Tincturæ Cannabis Indicæ..... $\mathfrak{m}\mathfrak{x}$
 Spiritus chloroformi..... $\mathfrak{m}\mathfrak{x}$
 Tincturæ kino..... $\mathfrak{z}$ j
 Aquæ menthæ piperitæ ad..... $\mathfrak{z}$ j)

"in a modified dose, will be found very ser-
 viceable. Being connected with a dispen-
 sary where thirty to forty cases of diarrhœa
 presented themselves daily for treatment dur-
 ing the months of August and September,
 and where a great variety of remedies were
 tried, so great was the superiority of Indian
 hemp above the others, that the patients
 themselves got to know it, and invariably
 asked for the green medicine."

We have been in the habit of prescribing
 it in nearly all forms of diarrhœa with
 marked benefit, combined with medium
 doses of morphine. In summer diarrhœa
 the effects are very striking. There is no
 necessity to record cases, they are very much
 alike; the great depression, the frequent
 watery stools, the vomiting, and the cramp-
 like pains are very quickly relieved, the ap-
 petite speedily returns, and by the following
 or third day the cases are practically well,
 except for some weakness and debility.
 The formula we generally use for an ordinary
 adult is:

R Tincturæ Cannabis Indicæ..... $\mathfrak{m}\mathfrak{x}$
 Liquoris morphinæ..... $\mathfrak{m}\mathfrak{x}$ v vel $\mathfrak{m}\mathfrak{x}$
 Spiritus ammoniæ aromatici..... $\mathfrak{m}\mathfrak{x}$ xx
 Spiritus chloroformi..... $\mathfrak{m}\mathfrak{x}$ xx
 Aquæ ad..... $\mathfrak{z}$ j)

To be repeated every 1, 2, or 3 hours according to circumstances. Directions: *No food for several hours, but a little brandy and water.* We have not seen one case run on to a fatal issue under this treatment.

It appears to act by increasing the astringent and anodyne properties of the morphine (the dose of morphine would have very little effect alone), by its stimulant effect on the nervous system, and by improving the appetite; thus enabling the system to quickly overcome the marked depression and exhaustion. Most remedies in this disease rather retard the return of the digestive functions, but from our experience Indian hemp markedly accelerates it. Indian hemp seems also to frequently counteract the bilious action of morphine, as well as the loss of appetite, and allows it to be given where it otherwise would not be tolerated.

In other forms of gastro-intestinal disturbance it is also valuable, probably for the same reasons. It was of marked use in a case of subacute gastro-enteritis, which had existed for a few weeks before it came under our care, in a girl aged 13 years, showing the following symptoms:—marked anæmia, which had gradually come on after the other symptoms; constant pain over the abdomen, especially in the epigastric region, increased on pressure and after food; tongue covered with yellowish-white fur; loss of appetite; vomiting at variable times after food of partly digested material; diarrhœa, six or eight stools in the day which were watery and green, containing partly digested food material; some rise in temperature—a little over 100° F. She was first treated with bismuth, then with effervescent mixtures, with no benefit; then with the cannabis mixture (modified to suit her age), and the symptoms very quickly subsided, the vomiting and diarrhœa were checked, the pain ceased, and appetite returned. By the end of the week all the symptoms had disappeared except the anæmia, which persisted for a short time longer.

In cases of tuberculous diarrhœa we have not seen much benefit, beyond a slight relief of symptoms for a short time, though we have not had sufficient experience in this type; nor in the excessive diarrhœa in typhoid fever.

The use of Cannabis Indica in diarrhœa is certainly not new, as the quotations previously given will show; and an old dispensing chemist informed us that some twenty years ago he knew it to be frequently prescribed; but probably from the introduction of many new remedies, and from good specimens of

the drug having been not always attainable, it has with many other valuable remedies been temporarily forgotten. We can find no mention of it in modern works on medicine. —*Practitioner, July, 1887.*

CORRESPONDENCE.

A Correction.

EDS. MED. AND SURG. REPORTER:

In your issue of August 20th is a copy of a letter, "A visit to Dr. Hiram Corson," taken from the *N. Y. Medical Journal*, in which an error occurs in regard to the dose of the infusion of cimicifuga, giving it in teaspoonful doses three times a day. It should be from a tablespoonful to a wine-glassful. The tinct. or fld. ext. can be used in teaspoonful doses.

The same error occurred in the paper from which the letter was taken, and I have already had it corrected there. Trusting you will do the same at a very early date,

I am very truly,

1527 Green St., MARY WILLITS, M. D.
Philadelphia, August 24th, 1887.

A Rare Dislocation.

EDS. MED. AND SURG. REPORTER:

Sirs: I met a dislocation which I think is quite rare. It is a dislocation of the upper end of the fibula backwards in a child sixteen months old. The child was sitting on the floor, when an older one fell from a bench above upon the legs of the little patient. The mother was not aware of the accident at the time, and several days later consulted me, saying that the child suddenly lost the power of locomotion. It was an extremely difficult diagnosis to make, since the fall of the older child had failed to attract any attention.

Hamilton (*Fractures and Dislocations*, in edition of 1880) says simple traumatic dislocations, which can only occur forwards or backwards, are very rare, and relates three cases of this accident.

It may be of interest in this connection to mention a very peculiar deformity which resulted from this dislocation. The extensor longus digitorum seemed to be completely paralyzed, giving to the toes a "dropped" appearance, like the drop wrist in lead poisoning. This deformity led me to examine the spinal column for the difficulty, and only accidentally did I discover the condition of the fibula. H. L. ROSEBERRY, M. D.

Mellonsburgh, Ohio, Aug. 18th, 1887.

EDITORS MED. AND SURG. REPORTER :

Sirs.—An article in a recent number of the REPORTER, giving an instance of the poisonous but curative effects of a dose of morphine, reminds me of a similar experience in the first year of my own practice.

A middle aged married woman, subject to occasional attacks of asthma of a severe type, sent for me, on the advent of an unusually hard attack, to afford her medical relief. The attack proved very stubborn as well as lasting, for after more than two weeks of unremitting effort on my part, aided by the counsel of an old practitioner, my patient was worse rather than better. On the evening in question, I found her in so much distress that I determined to relieve her or, as we say, "know the reason why."

My patient, also, begged for relief or death. I at once prepared a hypodermic of morphine, guessing at the quantity, which was not less than one-half grain, and probably about three-fourths of a grain, and injected it into the arm with the assurance that she would soon feel better. In about twenty minutes she became so wild and restless that I was alarmed. In ten minutes longer I summoned the family, for I believed her to be dying. Within forty-five minutes after I had given the injection, she was quiet and wanted to sleep, but as soon as she fell asleep the breath would stop, and in one or two minutes she would wake up in agony. I antiodoted the morphine with belladonna, and stimulated with wine of ammonia. About two o'clock in the morning she was so much better that I left her in care of another person, and lay down on a lounge in the room. In the morning and through the day she felt very comfortable, and was much surprised at the absence of her enemy the asthma. From this time forward improvement was steady and unbroken, and with the use of very little medicine, and that of a general character. She remained free from asthma until her complete recovery some five or six weeks after. I nearly poisoned, but a year later she was still free from the trouble. Moving away about this time I heard nothing of her for four or five years, when a friend reported that she was still comparatively free from her asthmatic trouble. I have always attributed her prompt recovery to the powerful impression made by the large dose of morphine on her system in some way such as to prevent the ready return of the trouble.

Occasional experiences in the administration of strong poisonous doses of medicines under marked conditions all go to show,

that in some way not easily or clearly explainable, a profound shock to the nervous system reacting to the very centres, will often afford the relief sought, which otherwise has been found impossible of attainment.

I am not anxious to repeat the experience I had with my patient; still, under the same conditions, I would probably try, as a forlorn hope, the effect of a medical shock. Had my patient died, I have strong reasons for believing that the matter would have been settled in court.

In closing I wish to add, that I like the REPORTER better than ever under its new management. W. C. EUSTIS, M. D.
Flarmington, Minn., Aug. 17, 1887.

Remarkable Case of Typhoid Fever.

EDS. MED. AND SURG. REP.:

Horace F., aged 15, previously very healthy, was very well developed and muscular, weighing 160 pounds.

Began to complain on the 6th of August of slight weariness in his limbs, and lack of energy. Had a slight chill on the 7th inst., took to bed in the afternoon of the 8th. I was sent for on the morning of the 9th, and found his condition as follows: Pain in the left iliac fossa, with only slight tenderness in the right iliac fossa; loss of appetite; nausea, with occasional vomiting; heavily coated tongue, and diarrhœa. Pulse, 100; temperature, 102. I saw him on the 10th, and he presented the following conditions: Pulse 114, very feeble; temperature, 104. Nervous symptoms marked, answered questions at hap-hazard, talked incoherently, had incontinence of urine and feces, and made efforts to get out of bed. His condition on the morning of the 10th was: Pulse, 120, very quick and feeble, scarcely perceptible; nervous symptoms more marked; had carphalugia, picking at the bed-clothes, and subultus tendinum.

Digestive symptoms were: Tongue began to get dry in the center, and fissured; was protruded, with apparent hesitation and difficulty. Teeth and lips were covered with black sordes, as is usually seen in the 2d and 3d week. Had an attack of severe epistaxis the previous night.

I saw him on the evening of the same day, when the following conditions were noticed: Pulse, 130; temperature, 104 $\frac{3}{4}$; tongue very dry and fissured, the patient very delirious, talking and moaning constantly.

He had a profuse attack of epistaxis, lasting for an hour, during my visit, which was checked by applications of ice to the head

and nape of neck and insufflations of tannic acid. Took no nourishment any more, and at 11.30 he passed quietly away to another world.

Having never seen a similar case during an epidemic and through my 3 years of instruction at the University Hospital, I deemed the case worth reporting.

The remarkable features of the case were the abruptness of the attack, with very slight prodromic symptoms, the marked high fever and pulse in the first week, as also the marked nervous symptoms and death of patient on the 3d day of the disease.

DR. JOHN P. HILLEGASS.

Pennsburg, Pa.

A Correction.

EDS. MED. AND SURG. REP.:

Dear Sirs:—Dr. Cale's name has been misspelled in the clinical report of the Surgical Clinic of the St. Louis College of Physicians and Surgeons, reported in the issue of August 13th. Please to correct it in your next issue, and oblige.

LOUIS BAUER, M. D.

St. Louis, August 22, 1887.

NEWS AND MISCELLANY.

The International Medical Congress.

A correspondent of the *Med. News* (Aug. 27, 1887), sends the following sketch of each days' proceedings of the Int. Med. Congress:

In spite of the depressing influences of the heated term, busy preparations are going on by all concerned in the local management of the International Medical Congress. The office of the Secretary-general, Dr. Hamilton, shows tables filled with proof-sheets, titles and abstracts of papers, programmes, letters, etc., and medical men are constantly coming and going, seeking information on matters pertaining to the Congress. Dr. Hamilton showed me a closely printed pamphlet in small type, a proof copy, in which were embodied the titles of papers to be read and presented; it (the pamphlet) had already reached sixty-four pages, and the eleventh section, that of Ophthalmology, was not concluded, there being six more sections to be included, so that it would be impossible to give a fair idea of the material preparing without taking up a great deal of space.

So far, 338 foreign delegates are on the list as having expressed their intention of being in attendance.

The general sessions will be held at Albaugh's Opera House, which is centrally located on Fifteenth street, just below Pennsylvania Avenue, and looks out on the grounds of the President's House and Washington Monument. It ought to be cool and well ventilated. Its seating capacity is about thirteen hundred, including the balcony seats; the floor, comprising what is known as the orchestra and orchestra circle, seats seven hundred and eighty. The stage is moderately large, and the acoustics are pretty good. The Sections have also been provided with suitable accommodations.

The programme for the meetings is about as follows:

Monday, September 5. General meeting at Albaugh's Opera House, beginning at 11 A. M. Forenoon: Organization of the Congress, report of Secretary-General, report of Chairman of Local Committee, Address of Welcome by Secretary of State Bayard, Address by the President of the Congress, and other addresses. The Sections will meet at 3 P. M.

Tuesday, September 6, 10 A. M. General addresses: First, Dr. Austin Flint, of New York, on "Fever, Its Causes, Mechanism, and Rational Treatment." Second, Dr. Mariano Semmola, of Naples, Italy, on "Bacteriology and Its Therapeutical Relations. The Sections will meet daily from 11 A. M. to 1 P. M., and from 3 P. M. to 6 P. M.

Wednesday, September 7, 10 A. M. General addresses: First, Dr. P. G. Unna, of Hamburg, Germany, on "The Relations of Dermatology to General Medicine." Second, Dr. G. Fielding Blanford, of London, on "The Treatment of Recent Cases of Insanity in Asylums and in Private Houses."

Thursday, September 8, general meeting at 10 A. M. General addresses: First, Dr. A. Luteaud, of Paris, on "The Influence of Discoveries of American Surgeons on the Development of Gynecology in Europe." Second, Dr. Neudörfer, of Vienna, on "The Military Medicine of the Present and that of the Near Future."

Friday, September 9, general meeting at 10 A. M. for general business.

Saturday, general meeting at 10 A. M.; adjournment.

Although, as stated before, it is impossible to do justice to the material to be presented at this meeting, I cannot avoid noting a few papers on interesting subjects accompanied by the names of prominent medical men from abroad. Thus, in the section on *General Surgery*, William MacEwen, of Glas

cow, Scotland, will read a paper on "Brain Surgery." Edmund Owen, of London, has two papers on "The Surgery of the Hip-Joint: Paracentesis of the Articulation in the Early Stages of Disease of the Hip-Joint," and "The Distention of the Capsule in Disease of the Hip-Joint." Dr. Ollier, of Lyons, has a paper on "The Results of Resection in an Orthopedic and Functional Point of View." Dr. Leon Le Forte, of Paris, on "Gradual Dilatation of the Urethra." Neudörfer, of Austria, has several papers to present, dealing chiefly with problems in military surgery; he is Sanitary Chief of the Fifth Army Corps. Sir Thomas Longmore has a paper on the soldier's equipment for field dressing of wounds in time of war. Dr. Joseph Ewart, of London, has a paper on "Cholera," and Dr. Frederick Esmarck, of Kiel, a paper on "Field Dressing of Gunshot Fractures of the Lower Limbs in Connection with Transportation."

In the Section on *Obstetrics*, Prof. Emil Ehrendorfer, of Innsbruck, Austria, has a paper on "Puerperal Fever." Dr. Thomas More Madden, of Dublin, one on "Puerperal Septicæmia." Dr. M. Sänger, on "Conservative Cæsarean Section." Kirch, of Italy, on the same. Dr. Goelson Duncan, of London, gives a case of Porro's operation, and Prof. Lazarewitch, of St. Petersburg, a new normal (?) forceps. Lawson Tait has also a paper on "Tubal Pregnancy."

In other sections we note a paper by Prof. Rosenthal, of Vienna, on "Experimental and Clinical Observations of Cocaine." Dr. D. Hack Tuke, of England, on the "Care of the Insane." Dr. John Batty Tuke, of Edinburgh, on the "Legal Relation of Epilepsy." A paper on "Massage," by Dr. Charles Weber, in the Section of *Therapeutics and Materia Medica*, one by Dr. G. Ludvic Hirschfeld, of Paris, on the "Inefficacy of Ferruginous Injections," and one on the "Poison of the Cobra," by Dr. T. Gnezda, of Berlin. Dr. Dudley Wilmot Buxton, of London, gives "Experimental Studies in Asphyxia." In *Otology*, Dr. B. Loewenberg, of Paris, has a paper on the "Treatment of Tinnitus Aurium." In *Anatomy*, Reginald Harris, of Liverpool, on the "Bladder;" Dr. William Mitchell Banks, of Liverpool, on the "Wolffian Bodies." In *Diseases of Children*, Dr. E. Bouchut, of Paris, on "Tubage of the Glottis." In the Section of *Dermatology and Syphilography*, are papers by Mr. Jonathan Hutchinson, of London, Dr. P. G. Unna, of Hamburg, Dr. T. Colcott Fox, of London, and several other well-known foreign dermatologists.

The Section on *Public and International Hygiene* is favored with papers by Thudichum, of London, Antoine Magnin, of France, Tommasi Crudeli, of Italy, Domingas Freire, of Rio Janeiro, Benjamin Ward Richardson, of London, Mapother, of Dublin, and others.—*Med. News*, Aug. 27, 1887.

The Rocky Mountains for Recreation.

Why do so few of our young men go West for recreation? There is no land where nature recreates a man as she does there. You literally renew your youth. The climate is invigorating beyond words. For nervously exhausted men, for weary brains, there is simply nothing to touch it. I have gone to the [Rocky] mountains thoroughly fagged out, unable to sleep well or eat well—life a burden, and work an impending horror. In a fortnight I have been eating as many meals a day as I could prevail on my men to cook, and have been glad to fill up chance spaces in my internal economy with raw bacon. Yes, many a time, after a monumental dinner, when we have gone into camp at five in the afternoon, have I eaten with relish that most lasting of all provisions—a piece of raw bacon—before turning in. It is true, some, at first, find the rarefied atmosphere of the mountains trying to chest or heart, and many also complain of loss of appetite and loss of sleep; but if the man is sound in limb and lung, and if he does not over-do it or over-exert himself at the very beginning, but does take regular exercise, in ten days or so all life seems to awaken within him; he may not sleep so long or so heavily, for he has probably camped at an altitude of eight or nine thousand feet (excellent camping-places are sometimes found at a height of ten thousand feet or over), and he does not need as much sleep as though he were at sea-level. He may puff and blow like a grampus as he faces a moderate hill; for he has scarcely realized yet that the atmosphere is so rare that he must boil his potatoes (if he is lucky enough to have any) for at least two hours, and he will do better if he boil them all the morning, and that he cannot, by twenty-four hours' boiling, make beans soft enough to feed to his horse. But he is growing younger, not older. The world of cark and care seems very far away, walled out by the heavy mists that roll up from the plains. What a fool he was to bother his soul, as he did, with a thousand useless things!—W. S. RAINSFORD, D.D., in *Scribner's Magazine* for September.

Low Water in Rivers.

A very earnest and extended communication was received by Governor Larrabee from an intelligent Iowa lady calling attention to the low state of water in our rivers—to the fact that few of the dams in the rivers had enough water in them to run over the “breast of the dam,” and that in consequence the water was stagnant, covered with green slime, and disease-producing. As a remedy, she urged the Governor to order all the dams drawn off so that this sluggish water might be set in motion, and thereby purify itself—at least relieve the localities contiguous to the dams from their poisonous effluvia.

The communication was referred to the State Board of Health for reply. In the reply we called attention to the fact abundantly attested by careful observation, that the remedy proposed would really be more dangerous to the public health than the present condition. So long as the water covers the bed of these dams and rivers, the danger from malaria is infinitely less than it would be were these dams drained and the bottoms exposed to the hot sun, producing fogs by night, and still more poisonous exhalations by day. It is not the pond full of water so much as the pond drying or dried up that produces sickness.

We called attention to the further fact that the water in these dams though not apparently having any egress, must necessarily find some outlet whereby in a measure it purifies itself, since the water, continuously flowing in from above is just about as continuously and liberally flowing out below. Hence, we suggested that the dams be not ordered “drawn off”—but that rather we all petition the powers that be ordained to send “the latter” if not the early rain, that the “thirsty pools may rejoice.”—*Bull. Iowa State Board of Health*, August, 1887.

Potable Water.

Inquiry is frequently made of this office if there is no way to ascertain whether or not water is safe for potable use, except by analysis. Two simple tests are here given, which will answer very well:

Fill a thoroughly cleaned pint bottle three-fourths full with the water to be tested; add to it half a teaspoonful of clean white granulated or crushed loaf sugar; stop the bottle with a new, clean cork or glass stopper, and set the bottle in the sunlight in a moderately warm room. If in twenty-four or forty-eight hours the water becomes cloudy or

milky, it is unfit for domestic use. While the absence would not in certain cases prove the water to be good, the test is a good one for general purposes.

Another test is: Fill a common tumbler with the water, and put into it six drops of saturated solution of permanganate of potash, to be had at any drug store. If the water turns brown in an hour, it is unfit to drink.—*Bull. Iowa State Board of Health*, Aug. 1887.

Label Paste.

A writer in the *English Mechanic* gives the following formulæ:

1. Gum tragacanth, one ounce; gum Arabic, four ounces. Dissolve in water, one pint; strain and add thymol, fourteen grains, suspend in glycerin four ounces; finally add water to make two pints. This paste will keep indefinitely, and is suitable for labeling slides, glass bottles, wooden boxes, etc.

2. Rye flour, four ounces; powdered acacia, one-half ounce. Rub to a smooth paste with eight ounces of cold water, strain through cheese cloth, pour into one pint of cold water, and apply heat until thickening ensues; then cool, and add one ounce of glycerin and twenty drops of oil of cloves. This paste keeps well, and is suitable for both glass and wood.

3. Rye flour, four ounces; water, one pint; nitric acid, one dram; carbolic acid, ten minims; oil of cloves, ten minims; glycerin, one ounce. Mix the flour and water, strain through cheese cloth, and add the nitric acid. Apply heat until suitably thickened, and add the other ingredients when cooling. This is suitable for labeling bottles, tin or wooden boxes, and will not spoil.—*The Western Druggist*, August, 1887.

A Castor-Oil Draught.

A correspondent of the *British Medical Journal* communicates the following pharmaceutical hints. The first is for the easy administration of castor-oil:

Ol. ricini.....	3iij
Tr. rhei co.....	3j
Ess. menth. pip. vel. cinnam.....	ʒv
Shake, and add	
Liq. magnes. bicarb. recent, ad ...	3j

Five drachms of oil can be given in an ounce-and-a-half draught. He has always failed to make it in quantity, and says the ingredients should be mixed in the phial they are to be sent in. The B. P. solutions of morphine always form a deposit on the stopper or neck of the bottle; this can be

prevented by the addition of half a drachm of glycerin to each ounce of the solution. Ungt. gallæ c. opio, no matter how well rubbed up, is always gritty; this can be completely removed by rubbing the opium with a few drops of hot water.—*The Chemist and Druggist*, August 13, 1887.

Carnegie's Cure for Seasickness.

"Nobody need be seasick," explained Andrew Carnegie, the millionaire, "if he takes precautions and possesses a moderate degree of good health. This malady is often a bugaboo which people assume. The best medical authorities contend that the malady is an affection of the brain and spinal marrow rather than the stomach, and is after all, only the effort of the brain to accustom itself to the motion of the ship and the sound of machinery. It follows that will-power is a large factor in warding off the dreaded illness. Make up your mind to be well, and after you are under way take a small powder of bromide of soda, which your chemist will prepare in proper doses, put it in half a glass of water, and renew the dose whenever you feel the slightest symptoms of nausea. Your effervescent salts before breakfast will do the rest of the preventive cure.

"In any case, keep on deck as much as possible, dress too warmly rather than too coolly, and walk the deck an hour or two daily, rain or shine. Avoid over-eating the rich food with which ocean steamers are invariably stocked. There is no occasion to change your mode of life as to diet, because you are on the water, unless you have been extravagant; then let it be less so. Eat regularly, and aim to ingratiate yourself with your fellow passengers at table. You are all at the mercy of the treacherous waves. Surely, then, haughtiness or surliness is absurd; in fact, I would recommend three arbitrary ingredients for securing good, moral, mental, physical and social results, and these are good nature, will power, and bromide of soda."—*The Western Med. Reporter*, August 15, 1887.

Items.

—Yankee shaving soap is prepared according to the following: Take 3 pounds white bar soap, 1 pound Castile soap, 1 quart rain-water, $\frac{1}{2}$ pint beef gall, and 2 fluid ounces oil turpentine. Dissolve the soap, first sliced in the water, by heat, add the other ingredients, stir until cool, then perfume with oil of bitter almonds or rose.—*The Western Druggist*, August, 1887.

—Mrs. Rose Terry Cooke says that if American women wish to be healthy they must learn to live in fresh air. She advises them to open their windows, wear flannel night-gowns, and take a jug of hot water to bed if they are cold, but never to sleep with closed windows; air all their clothes and their rooms daily, eat simple, wholesome food, wear boneless waists, button their skirts on them, and take the heels off their boots.

—"Only fifty years ago," says Sir Spencer Wells, "the average duration of human life in Great Britain was thirty years: to-day, according to statistics, it is forty-nine years. In fifty years the population has increased by eight millions. At least two millions of this increase may be put down as the fruit of improved sanitary and medical work, and of victory over preventable sickness."

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from August 21, 1887, to August 27, 1887:

Major W. S. Tremaine, Surgeon, found incapacitated for active service by an Army Retiring Board, extension of leave of absence on account of sickness still further extended until further orders. Par. 9, S. O. 192, A. G. O., August 19, 1887.

Major John H. Bartholf, surgeon, leave of absence extended one month. Par. 7, S. O. 196, A. G. O., August 24, 1887.

Capt. Julius H. Patzki, Assistant Surgeon, granted leave of absence for one month. Par. 15, S. O. 195, A. G. O., August 23, 1887.

Capt. Washington Matthews, Assistant Surgeon, ordered to proceed to Phoenix, Arizona Ter., on public business, and on completion thereof to return to his proper station, S. G. O. Par. 21, S. O. 195, A. G. O., August 23, 1887.

Capt. Blair D. Taylor, Assistant Surgeon, granted leave of absence for 20 days, to take effect on or about August 31, 1887. Par. 7, S. O. 193, A. G. O., August 20, 1887.

1st Lieut. E. L. Swift, Assistant Surgeon, ordered to report in person to Commanding General, Division Pacific, for duty with troops at Round Valley, Indian Reservation. Par. 20, S. O. 195, A. G. O., August 23, 1887.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the week ended August 27, 1887:

Surgeon P. H. Bailhache, granted leave of absence for thirty days. August 26, 1887.

Passed Assistant Surgeon H. R. Carter, granted leave of absence for twenty-seven days. August 25, 1887.

Passed Assistant Surgeon H. W. Yemans, resignation accepted, to take effect September 30, 1887, and leave of absence extended to that date. August 24, 1887.

Seaton Norman, granted leave of absence for six days, on account of sickness. August 27, 1887.

ORIGINAL DEPARTMENT.

LECTURE.

TREATMENT OF JAUNDICE BY COLD WATER ENEMATA.—A CASE OF CIRRHOSSIS OF THE LIVER WITH JAUNDICE.

A clinical lecture delivered at the Philadelphia
Hospital,

BY J. H. MUSSER, M. D.

Attending Physician to the Philadelphia Hospital,
Pathologist to the Presbyterian Hospital, etc.

Reported by William H. Morrison, M. D.

GENTLEMEN :

This patient was before the class two weeks ago suffering from catarrhal jaundice. The treatment which was pursued was that which is known as the method of Krall, which is recommended by the German writers and is said to have been quite successful, namely, the administration of enemata of cold water. This was given three times daily and continued for ten days. At first the temperature of the water used is 55° or 60° , and each day the temperature is slightly increased until by the tenth day it has reached 90° . With the exception of rest and regulation of diet, nothing but the administration of the enemata has been employed in this case. Marked improvement was manifest on the second or third day after the treatment was begun. There is now scarcely any pigmentation of the skin, and there is only a slight discoloration of the conjunctiva. The gastro-intestinal symptoms which were present have also improved. While the disappearance of the jaundice and

the other symptoms have been satisfactory, the improvement has not been so striking as in other cases in which I have employed this treatment.

I wish to show you, in connection with the case you have just seen, another patient, who was admitted to the hospital one week ago, suffering with extreme prostration and dyspnoea and having enlargement of the abdomen. The patient is extremely emaciated, with a yellowish or sallow tinge of the countenance and an appearance of distress. There is, as you can see, fullness of the venous capillaries of the face. There is also slight oedema. The dyspnoea was found to be due to enlargement of the abdomen pressing the diaphragm upwards. On inspection we find that the enlargement is uniform. There is no irregularity whatever. The enlargement is symmetrical. The abdominal walls are extremely dense and glistening. The veins are enlarged and the capillaries are full. Palpation confirms inspection and, in addition, shows the presence of liquid. Fluctuation is readily detected. Percussion, with the patient on the back, shows a tympanitic area over the central portion of the abdomen and marked dullness in both flanks and in the epigastric region. The area of dullness changes as the position of the patient is altered. No friction fremitus is detected, and, in fact, as the respiration is chiefly costal, very little movement of the abdomen takes place. Mensuration shows that the enlargement of the abdomen is most marked just above the umbilicus. The ratio existing between the measurement from the umbilicus to the xiphoid cartilage, and that from the umbilicus to the symphysis, is normal, the

navel being about one inch nearer the sternum. I mention this because there are cases of fluid in the peritoneal cavity, especially in ovarian tumors, where there is a marked alteration of these measurements, the navel being nearer the symphysis.

What is the cause of this accumulation of fluid? In the first place, from our knowledge of morbid anatomy, we know that such an accumulation of fluid must be due either to conditions of the general circulation whereby there is obstruction, as in cardiac or renal disease, causing an exudation of serous fluid into the lymph spaces (and the peritoneal and pleural cavities are only large lymph spaces), or to local conditions of the circulation within the peritoneal cavity; for, as you remember, there is within the abdomen a minor circulation; or quite frequently it may be due to diseases of the peritoneum itself.

Is there any acute disease of the peritoneum in this patient? Peritonitis can at once be eliminated by the absence of fever and the other symptoms of this affection. Besides, the history of the patient would indicate that this affection has been developing for some time, and must therefore be due to some chronic process. Is there simple chronic inflammation of the peritoneum? The history of the case does not point to such a condition, and in chronic peritonitis there are other symptoms besides ascites. There is often the fremitus to which I have already referred. In chronic inflammation of the peritoneum, the effusion is not great in amount, is confined to certain localities by numerous adhesions, and localized areas of dullness will be found. In chronic peritonitis, also, the contour of the abdomen is usually different from what it is here, being irregular, and there is absence of enlargement of the superficial veins.

In tubercular peritonitis, which is a more frequent cause of ascites than is simple chronic peritonitis, there is evidence of tuberculosis found in other organs. There is in addition marked fever, sometimes of a hectic nature; there is also emaciation which is often more extreme than it is here. In tubercular peritonitis the contour of the abdomen is often irregular, and the distension is usually not so great as in this case. There is therefore a relaxed condition of the abdominal walls, and often an enlargement of the mesenteric glands and omentum. I have shown you specimens in which there was enormous thickening of the peritoneum and omentum as the result of tubercular disease of those structures. This thicken-

ing is usually detected by dullness along the course of the transverse colon above the umbilicus, and must be distinguished from the hepatic dullness. This is done by finding a line of tympany between the dullness of the thick omentum and that of the liver.

Malignant disease of the peritoneum must also be considered. In this we have frequently ascites, as in this case; and we also have the presence of the cancerous cachexia with the occurrence of local symptoms due to the development of secondary deposits in important organs, as the liver, the stomach, or in the bowel, leading to alteration of function or obstruction of the viscera. The disease would also be likely to involve the glands of the groin or of the axilla, and there is especially apt to be in these cases a deposit of carcinoma about the umbilicus. We can in this instance readily eliminate affection of the peritoneum.

There are other accumulations of fluid to which I desire to refer before speaking of the effects of obstruction of the portal circulation. In females it is necessary to consider whether or not ovarian tumor is present. We also have renal cysts, which give rise to the physical signs of effusion. We have hydatid disease of the liver, or peritoneum. Ovarian tumor can usually be distinguished by the history of the case, the relation of the growth of the tumor to menstruation, and by physical examination. The swelling usually appears in one or other groin, and the contour of the abdomen is usually not symmetrical. The normal proportion of the measurements between the umbilicus and xiphoid cartilage, and the umbilicus and the symphysis pubis is altered. If an ovarian tumor is tapped, the fluid is found to be glutinous, and contains paralbumen. There is always absence of urea. The fluid in certain cases may be of a dark color. The fluid in ascites, due to peritoneal affections, is clear, of a straw color, with a specific gravity of about 1012, and contains albumen and urea. In carcinoma of the peritoneum, however, the fluid is often bloody. The study of the various kinds of fluids found in the peritoneal cavity is of course of extreme importance in regard to the diagnosis.

In their local appearances, both renal and hydatid cysts are characterized by smoothness of their surface and irregularity in outline of the abdomen and also by the characters of the fluid. In hydatid cysts we have the presence of hooklets, and there are local symptoms referable to the organs involved in the disease. In renal cysts there is a history of

some affection of the kidneys, possibly the previous passage of a calculus.

We come now to speak of disorders of the general circulation that may cause ascites. In this patient there is some general anasarca. There is œdema of the feet, and, on admission, there was quite marked œdema of the hands. The history of this case points rather to a local than to a general affection. If the condition were due to some disturbance of the general circulation, such as cardiac disease; or, if it were due to disease of the kidney, which is almost always a general disease, the affection of the kidneys being a local manifestation, as of arterio-capillary fibrosis, we should have a different history. The patient is forty-five years of age, and is a domestic by occupation. She has been a moderate drinker. She states that she has been always healthy, until the appearance of the present trouble, which developed three months ago. She first noticed swelling of the abdomen, which was associated with gastro-intestinal symptoms, especially the occurrence of vomiting at irregular intervals. There was some dull pain throughout the abdomen. Five months previous to admission she states that she vomited blood. This is all the history that we have been able to obtain, and the condition of the patient rendered it difficult to obtain even this. She further states that her health has been failing for two years.

There is no history of renal symptoms, and the examination of the urine serves to at once eliminate disease of the kidneys. The heart also is found to be normal. There is nothing to lead us to believe that ascites is due to any disorder of the general circulation. We must therefore consider it to be due to disturbance of the portal circulation.

In distinguishing the particular affection of the portal circulation which has given rise to the ascites, we must take into consideration the history of the case. In this patient the history points to that affection, which is quite common in this hospital, namely, cirrhosis. The age, the habits, the previous history and the gradually developing ascites, would lead us to look to the liver for the cause of the trouble. Under such circumstances we find the liver is contracted, and on percussion we find the normal area of hepatic dullness much diminished. In addition, there is slight icterus, as shown by the yellowish tint of the eye and of the mucous membrane under the tongue. We would at once consider this to be a case of cirrhosis of the liver, and the presence of the enlarged superficial abdominal veins confirms

this opinion. The peculiar cachectic appearance which this patient shows is very characteristic of the latter stage of cirrhosis. The absence of renal and cardiac lesions would also all point towards this affection.

There are other disorders which influence the portal circulation and lead to dropsy. One of these is perihepatitis, especially, syphilitic perihepatitis, with subsequent contraction. This perihepatitis usually develops secondarily to some local affection of the peritoneum, such as may be caused by ulcer of the stomach or the passage of gall-stones. Another cause is affections of the portal vein causing obstruction. This occasionally is a result of pyelophlebitis, especially of the adhesive variety, with the formation of thrombus in the portal vein. In this condition there is usually a history of some local abdominal trouble. One peculiar thing in thrombus of the portal vein is that, within twenty-four hours after tapping, the abdomen is again distended to its previous size. We have not used this test in the present case, because the patient has improved. If after tapping we find the accumulation quickly returns, we should possibly infer the existence of thrombosis of the portal vein, but this may be present in cirrhosis. The symptoms point to obstruction of the portal circulation with the occurrence of ascites, hemorrhage and the enlargement of the superficial abdominal veins.

When admitted the patient was extremely weak and the first indication for treatment was the use of stimulants. It may be said, "Why use stimulants since this affection of the liver is undoubtedly due to the abuse of stimulants?" The damage has already been done and it is not likely that in moderate quantities, any bad effect will be produced. The general condition absolutely called for the use of stimulants. In these cases it is also well to stimulate the renal circulation. The skin in like manner should be remembered. In this case we have used copaiba as a stimulant of the renal secretion with quite satisfactory results. The oleoresin of copaiba in five minim doses was given three times a day. Other diuretics may be used in addition. Digitalis is of much value. In this instance the copaiba is acting so satisfactorily that we shall not change, unless the condition of the stomach requires it.

The question as to the propriety of tapping arises. When I first saw the patient, I thought that this would have to be done, but she was so much excited at that time that I did not consider the operation warranted. Tapping was therefore postponed. It should

be done not only on account of the large accumulation of fluid, but also on account of the pressure effects which this collection produces. Tapping is usually followed by the discharge of a larger quantity of urine than has been previously passed. The removal of the fluid relieves anasarca and the secondary congestion of the mucous membrane of the stomach and bowels.

This case, therefore, presents a perfect picture of cirrhosis of the liver in the third stage. The prognosis is, of course, grave, yet even in this stage cases have been so relieved that they have lived for a long time. Undoubtedly the best method of accomplishing this is by frequent tapplings. In one reported case tapping was performed some forty or fifty times, and finally the ascites entirely disappeared, and the patient became comparatively well. Drugs used for their effect upon the liver are, of course, out of the question. It is sometimes said that if iodide of potassium is administered in the third stage, the progress of the disease may be checked. There has never been any positive proof that it has this power.

There is another interesting condition, and that is the occurrence of small purpuric spots on the arms and eyelids. These often occur in cirrhosis; and indicate not only a depraved condition of the blood, but also a congested state of the capillaries. Jaundice does not usually occur in cirrhosis, except possibly in the first stage. In this case it is due to the secondary congestion of the mucous membranes arising from the obstruction of venous radicles in the liver, in that way finally causing gastro-intestinal catarrh.

There are cases of cirrhosis of the liver where the organ is enlarged instead of contracted. This occurs most frequently in women. They may be the result of alcohol, but they are often secondary to long continued jaundice due to chronic obstruction in the biliary passages. We shall carefully watch this case and report the result to you.

—Prof. Virchow, known not only as a celebrated physician, but also as an archeologist of renown, will finish his vacation by accompanying the famous Dr. Schlie-mann on his visit to Egypt next spring. He may, perchance, find his "cellular pathology" entombed in some of the Theban catacombs.—*Weekly Medical Review*, August 20, 1887.

COMMUNICATIONS.

MISTLETOE: ITS PHYSIOLOGICAL ACTION AND THERAPEUTIC APPLICATIONS.

BY R. L. PAYNE, M. D., LEXINGTON, N. C.

Overburdened as is now the Pharmacopœia with new remedies, any well-meaning physician should hesitate long and consider well the merits of any proposed new drug before he calls attention to its virtues. Feeling this, it is with extreme diffidence that I comply with the call of the REPORTER for my experience with mistletoe; and only because, after a careful study of its physiological action, and after testing its therapeutic virtues for more than nine years, I am convinced that its uses are not sufficiently understood by the medical profession, have I determined to prepare this little sketch.

Mistletoe, the *Viscum album* of Linnæus, the *Viscum flavescens* of Pursch, or *Phoradendron* of Nuttall, is a small, parasitic evergreen shrub of the natural order, *Loranthaceæ*, and grows chiefly upon deciduous leaved trees.

The *viscum album* is indigenous to Europe; the *phoradendron flavescens* is an American species, growing mostly on the elm, oak, locust, black-gum and persimmon trees, its habitat being in the Southern States, extending northward as far as New Jersey, and westward to the Mississippi Valley. The leaves of the *viscum album* are lanceolate or spatulate, obtuse and entire; those of the *phoradendron flavescens* are obovate or oval, fleshy.

Both plants are brittle, of a yellowish-green color, much branched, and bearing a flower monœcious and in clusters, and the fruit, a berry, small, white and waxy-looking.

Mistletoe has been analyzed by Gaspard, Funcke and others, who find it to contain mucilage, sugar, an odorous principle, a fixed oil, tannin (in traces), a resin, and various salts. It also contains viscin, or bird lime, in small quantities, but this seems to be largely a product of fermentation. Mistletoe was formerly used by European physicians as a remedy in hysteria and epilepsy, but in these conditions its use has become obsolete.

In the year 1851, Dr. Turnipseed, of South Carolina, called attention to the ebolic action of a decoction of mistletoe,

but little attention was paid to the declaration. In the year 1878, renewed interest in the remedy was excited by an article written by Dr. Long (*Louisville Medical News*), in which the author speaks highly of the oxytotic virtues of mistletoe, claiming it to be far superior to ergot:

"1st. Because it acts with more certainty and promptness.

2d. That instead of producing a continuous or tonic contraction, as does ergot, it stimulates the uterus to contractions that are natural, with regular intervals of rest. Consequently, it can be used in any stage of labor, and in primiparæ where ergot is inadmissible

3d. It can always be procured fresh; does not deteriorate by keeping, and is easily prepared"

Cases have also been reported by European authorities, in which children, after eating of the berries, were seized with vomiting, great thirst, tenesmus, bloody and mucus stools, and in one instance collapse and death. Further than the gastro-enteric irritation which the symptoms in these cases indicate, nothing was published throwing any light upon the physiological action of mistletoe until in the *North Carolina Medical Journal* (May 1881), the writer published an extended series of experiments upon cold and warm blooded animals, from the results of which the following general summary of the physiological action of the drug was deduced, viz: "Mistletoe is an irritant of the gastro-intestinal mucous membrane. We also conclude that it exerts, in cold blooded animals, an action on the heart similar to digitalis, slowing its action by increasing the length of its diastole, at the same time increasing the length of its systole. In warm blooded animals its action on the heart is more like that of belladonna, its force not only being increased but its rate of impulse also, and—contradictory as it may seem—it must be that in frogs the heart is slowed by increase of its inhibiting control, and strengthened by stimulation of its vaso-motor ganglia; while in warm blooded animals the increase in strength and rate of the pulse is due not only to stimulation of the vaso-motor cardiac ganglia, but also to a paralyzing action on the pneumogastric terminal filaments. It must also be noted that in too large doses, or if its action is too long continued, mistletoe by over-stimulation of the cardiac motor ganglia exhausts their irritability and paralysis results. The action of mistletoe on the pupil is also evidence of its stimulant action on the sympathetic nerves;

and further it is seen that in both cold and warm blooded animals, mistletoe exerts a paralyzing action upon the spinal cord and its nerves, both of sensation and motion, but the action upon the heart and pupil indicate a stimulant effect upon the ganglionic nerves. Whether this paralysis depends upon a specific action on the cord, or whether it be due to a diminished supply of blood, the result of the stimulation of the vaso-motor nerves and consequent contraction of the arterioles, cannot well be determined, but the latter hypothesis I am inclined to adopt.

Mistletoe destroys the reflex functions of the spinal cord and lessens the electro-motor contractility of muscles."

As a result then, of this determination of physiological action, and knowing that the uterus, like all unstriped muscles, is almost entirely controlled by the ganglionic nerves, it is easy to understand the alleged oxytotic virtues of mistletoe; and since the publication of my paper above referred to, a number of trustworthy observers have testified to me of its efficiency. Indeed, I am prepared to endorse not only all that Drs. Long, Todd, Lane and others claim for it in this connection, but I would further add, that in those cases of post-partum hemorrhage in which the loss of blood has been extreme and the nervous shock so severe that we dare not give ergot, lest paralysis of the heart result, mistletoe, from its stimulant action on the heart, may be given with greater safety and with even more confidence as to the relief of the flooding, than ergot.

After an extended experience with mistletoe in cases of the retained placenta after abortion, I am fully persuaded that it will be found a most efficient remedy. Further, from its stimulation of the vaso-motor nerves and consequent contraction of the arterioles, mistletoe will be found to do good service in epistaxis, hæmoptysis, menorrhagia, metrorrhagia, and indeed all passive hemorrhages. That its action on the heart indicates its influence in all diseases of this organ characterized by weak action and low arterial tension I have been able to demonstrate in practice since I claimed for the remedy theoretical virtues in my former paper; and in *The Practitioner* (November, 1881), will be found a note on *viscum album* by Dr. Roswell Park, of Glasgow, who, referring to my paper, confirms my observations in this connection. Dr. Park states that "whatever the exact pathological condition might be, incompetency and tumultuousness, and distressing cardiac action were the immediate

symptoms calling for treatment in those that presented themselves. For this I prescribed 3 ss doses of the tincture every four hours with the best results; all the patients returning with the above symptoms ameliorated." He further states that the drug is one of no mean "physiological power," and "an excellent substitute for digitalis."

In concluding this hurried sketch, I trust I may be permitted to present a few clinical cases illustrative of the value of the remedy in some of the above-named conditions:

Case I.—Mrs. E. called me to attend her in her third confinement. She had called me several times when suffering with false pains, consequently I did not hurry; and when I arrived I felt convinced that true labor pains had not set in; indeed, I thought she might be several days from term. She, however, would not hear to my leaving, and after careful consideration I determined to give mistletoe a trial. The pelvis was very capacious, the vagina was larger and well lubricated with mucous, and though the os was *not at all* dilated, the cervix uteri was soft and cushiony to the touch. At the time of giving the first dose of mistletoe, she had been having pains for fifteen hours, and the os uteri was not in the least affected.

3.30 P. M. I gave fld. ext. mistletoe 3j. In fifteen minutes she began to have strong pains, and in forty minutes the os was as large as a silver quarter. I now gave another drachm of the fluid extract. Her pains increased in frequency till 4.30 o'clock; the intervals of rest were so short as to be scarcely perceptible, and from that time her pains were so severe as to excite my alarm lest an evil result should follow my meddling. At 9.40 p. m. she was delivered of a girl; the womb contracted well and she had a good getting up.

Case II.—My father and partner was called to a case of abortion, at the end of the third month, to deliver a retained placenta. His best endeavors failed to obtain the after-birth. Ergot was then ordered and administered for three consecutive days without result; there was an offensive discharge from the vagina and septicæmia seemed imminent. Dr. Payne then bethought himself of mistletoe, and had a strong decoction prepared from the green leaves and about half a teacupful administered at a single dose. In a short time violent uterine effort occurred and the placenta was expelled at a single pain. The woman complained that she felt as if she would be "turned wrong side out." Recovery followed with no untoward symptom.

Case III.—Mrs. T., being examined per vaginam, the cervix was found in a cancerous condition on the anterior surface, and the woman, who was in the third month of pregnancy was in the act of aborting. The foetus was soon delivered, but then all uterine action ceased and the after-birth was retained.

After waiting sometime in vain for a recurrence of action, a half-teacupful of a decoction of mistletoe was administered. In a short time pains again set in and the placenta was promptly expelled.

Case IV.—Mrs. B., a widow, aged 43, no children, applied for treatment, saying that for several months she had been under the care of different physicians without improvement. She suffered from metrorrhagia and had taken aromatic sulphuric acid, ergot, in truth nearly all the hæmostatics, without avail. She was very anæmic and much debilitated. She was directed to discontinue all other remedies and was ordered fld. ext. mistletoe in doses of 30 drops thrice daily. Under this treatment there was slight improvement, and the dose was increased to a drachm. Improvement was now more marked, but, fearing that the fluid extract was not as reliable as it should be, she was ordered a decoction of mistletoe (strength, mistletoe, two ounces, to water a pint and a half, boiled down to a pint and strained) in doses of one ounce every six hours. In a few days the hemorrhage ceased entirely and has not since appeared. The patient expresses herself as feeling better than she has for years, and is rapidly gaining flesh.

Case V.—Mrs. F., aged 27, married, and mother of four children. She tells me that during the last year she has at short intervals flooded severely, and at one time came near dying before a physician could be called. She has now been flooding for about a week, and, under the care of another physician, has taken various remedies without relief. Examination reveals the womb much enlarged and retroverted, the os patulous, soft, and spongy to the touch. She is now taking ergot without apparent good effect. I therefore discontinued the ergot and ordered fld. ext. mistletoe in drachm doses every six hours. She began at once to improve, and in two days the extract giving out and having no more at hand, she was ordered a decoction of like strength and dose as Case IV. After the first dose of this she ceased to flood, and an interval of six weeks having elapsed without further trouble, she was placed under treatment for the existing metritis, and has since borne two children and enjoys fine health.

Case VI.—Mrs. H., primipara, aged 45, is subject to frequent severe floodings. Was ordered to use the decoction of mistletoe steadily for several weeks. The floodings have not since recurred.

Case VII.—Mrs. N., widow, aged 65, very anæmic, and subject to frequently recurring and very profuse epistaxis. During an unusually severe fit of bleeding, after ergot had failed to give relief, she was advised to use a decoction of mistletoe. A good result was almost immediately obtained, and since that time she informs me she has frequently used the remedy for the same trouble and with universally good effect.

Case VIII.—Mrs. H., who is in the second stage of tubercular phthisis, has been bleeding freely from the lungs for a number of hours. Having no ergot at hand, a decoction of mistletoe was administered, and in less than an hour the hemorrhage ceased.

The following notes of two cases of bronchial hemorrhage treated with mistletoe were given me in a letter from a professional friend:

“No. 1. Second stage tubercular phthisis. Frequent large hemorrhages for over two years; ergot, salt, and gallic acid, he said, had been frequently used in previous hemorrhages; but they acted very slowly, and it was a question whether the hemorrhage ceased from their use. The attack he had, when I saw him, began after a violent fit of coughing when he was within a square of the hospital. He came to me at once, and I gave 3ss of the extract of mistletoe, and repeated the amount in fifteen minutes. After first dose hemorrhage ceased.”

“No. 2 said he had been perfectly well till within a week, when he had a cough, tight and ringing. Without apparent cause had violent hemorrhages, and came at once to hospital. Administered 3ss of extract at once; in 15 minutes the dose was repeated; 25 minutes after this hemorrhage ceased.”

And so I might go on citing case after case from my own practice and that of others, illustrative of the value of mistletoe in conditions similar to those above detailed; but these will suffice to indicate its usefulness. In country practice I almost daily prescribe a decoction of mistletoe, and I fully believe that at no distant day the remedy will enjoy the confidence of the profession at large.

SPEEDY AND FATAL CARBOLIC ACID
POISONING OCCURRING FROM
A UTERINE DOUCHE ADMIN-
ISTERED IN PUERPERAL
SEPTICÆMIA.

Reported to the Henry County, Tenn., Medical Society,

BY S. C. EDMUNDS, M. D., PARIS, TENNESSEE.

Mrs. Curtis, aged 18, of good physique, and of healthy parentage, was delivered by a midwife at 11 P.M., June 9th, of a well-developed female infant. She progressed favorably until noon of the 12th, at which time she was seized with a severe rigor, followed by high fever, and at 2 P.M., on the 14th, she had had two other rigors, and the case was developing serious symptoms. I was sent for and arrived at 7 P.M. Her pulse was 128, temperature in the axilla $103\frac{1}{2}^{\circ}$, respirations 32. The womb extended an inch above the umbilicus, was hard, but not tender. The bowels had been evacuated repeatedly by purgatives, and within the last forty-eight hours she had taken forty-eight grains of sulphate of quinine. This treatment had been instituted by her mother. I prescribed for her eight grains antifebrin to be given every four hours. This treatment was continued until 8 A.M., on the 15th, when the medicine gave out. I did not see her again until 8.30 P.M.; her pulse was 104, temperature $101\frac{1}{2}^{\circ}$; she expressed herself as having been much better, but was now growing worse in consequence of a rise of fever, and in thirty minutes thereafter it had risen to $102\frac{1}{2}^{\circ}$. The lochia was very fetid, and the womb as large as the day before; I concluded to wash out its cavity with a disinfectant solution; a drachm of liquid carbolic acid was stirred into a quart of warm water, and was injected with a uterine douche. The liquid was injected gently and returned freely through the escape-canula. It caused no pain while being given, but in a few moments she exclaimed, “Mother, run here and rub me, my blood has quit circulating, there are ten thousand needles sticking in me, I am burning up, give me water.” She drank the water and immediately vomited a greenish fluid and commenced trembling, and soon went into a clonic convulsion which lasted about ten minutes, during which time she did not lose consciousness. She said, “It is that old stuff you injected that is killing me, I taste it in my mouth.” On the cessation of the spasmodic movements her temperature was found to be 105° ; she was given eight grains of antifebrin, but rejected

it forthwith together with a large quantity of a black fluid, resembling "Black Vomit." She now became delirious and it required four to keep her in bed. I gave her morphine sulph. gr. $\frac{1}{4}$, atropine sulph. gr. $\frac{1}{100}$ hypodermically. In a few moments she was quiet, and her temperature rose to $108\frac{1}{2}$. She died at 10.55 P.M., one hour and forty minutes after the douche was used. Although the symptoms in this case did not resemble those ascribed to carbolic acid poisoning, yet I think that was the trouble. When we consider that there were two hundred and fifty-six drachms of water and one drachm of liquid carbolic acid, and that a full quart of the fluid returned as was ascertained by measurement it is easily understood that much less than the minimum dose of carbolic acid could have been absorbed. I do not think it probable that any of the fluid entered the peritoneal cavity through the Fallopian tubes as there was no tympanitis an hour after death. This is the worst mishap that has occurred to me in a long and active practice. Ever since the antiseptic treatment came into vogue I have been in the habit of giving uterine douches in cases of puerperal septicæmia, and, as I have been thinking, with marked benefit, and in no case did any untoward symptom result except in the one just reported.

STROPHANTHUS HISPIDUS.

BY JOHN AULDE, M. D., OF PHILADELPHIA.

Strophanthus hispidus was first brought to the notice of the public and the medical profession by Pelikan in 1865, who discovered that it was the active ingredient in an arrow poison used by the inhabitants in tropical Africa. It is one of several "Allied Plants" referred to in the U. S. Dispensatory under the head of Oleander, Nat. order, *Apocynaceæ*, and nearly a quarter of a century had elapsed before any attempt was made to establish its exact pharmacological position. Within the past few years, however, much has been accomplished toward establishing for it an important place in our materia medica. From the fact that a knowledge of this new remedy is not widely disseminated, it may not be out of place to note some of the facts which have been demonstrated as to its physiological action. It is stated that in 1877 Hardy and Gallois first isolated from the seed the poisonous neutral principle strophanthin, a white, crystalline substance, soluble in water, and slightly so in alcohol and chloroform, which was then supposed to be an alkaloid,

but later was found to be a glucoside. The honor of having discovered this principle is claimed by some for Professor Fraser, of Edinburgh, who published an account of his investigations before the British Medical Association in the latter part of the year 1885. Prof. Fraser has shown strophanthus to be a powerful muscle poison, the heart being early affected, and to him probably more than to any other, we are indebted to day for this valuable addition to our *armamentarium*. The estimated amount of strophanthin contained in the seeds is from eight to ten per cent., although the same principle is found in the leaves and bark, but in much smaller quantities. The hairy seed-crown contains *ineine*, a non-poisonous crystalline alkaloid, adopted no doubt from the name *inée*, which is that given to the plant by the natives of Africa.

Physiological Action.—Strophanthus acts on all striped muscular fibre, and a single injection of one fiftieth of a grain has been known to produce effects which were noticeable after an interval of eight days. As compared with digitalis, its effect on the heart is much more decided and powerful, while its action on the blood vessels is less, and yet the diuretic effect is most marked, as will readily be seen by reference to the following experiments:* "Comparative experiments upon the separated frog's heart showed that solutions of digitalin made by Morsin, of one part in over one hundred thousand parts, produces characteristic changes in the heart's action, but were sufficiently strong to kill the heart within two hours; but that a solution of strophanthin, one in six million, produced characteristic changes in the heart's action and complete stoppage of its contractions in extreme systole in about twenty minutes. In a frog whose central nervous system had been destroyed, a solution of digitalin, one in twenty thousand, passed through the blood-vessels, produced in six or seven minutes extreme contraction of the vessels, but no decided effect was observed with strophanthin in solution of one in three thousand, and a temporary effect merely with a solution one in two thousand. . . . It would therefore seem that strophanthus may be used with much greater advantage than digitalis in the treatment of cardiac disease, where the action of digitalis on the blood-vessels simultaneously with its action on the heart constitutes one of the strongest drawbacks to its successful employment."

*Prof. Fraser—*Brit. Med. Journ.*, Nov. 14, 1885, p. 904.

The question very naturally comes up here as to the *modus operandi* of this remedy acting as a diuretic, when it has all along been supposed, and by many the question was supposed to have been settled beyond a doubt, that digitalis acted as a diuretic by reason of its increasing blood pressure. Here we have a remedy which acts as a diuretic, and yet, when compared with digitalis in this respect, its action on the blood vessels is comparatively slight. According to the observation of those who have had the most perfect facilities for determining the matter, this diuretic effect is one of its marked characteristics, and it is recommended in cases of cardiac disease when the diuretic action is desired. Can it be that our teachings have been at fault in this important particular, and that digitalis does not act as a diuretic *cæteris paribus*, with the increase of blood pressure? I think this supposition can be satisfactorily explained by granting that both digitalis and strophanthus give increased power to the heart's action, and consequently that there is an increased activity in the vascular system, the result being that all glandular function is more perfectly carried on. This, of course, leaves out of the question all consideration of the effects of blood pressure in the structure of the kidney. In support of this proposition, I shall refer you to the results of recent investigations made by Heidenhain and his pupils, and referred to by Dr. H. G. Beyer, U. S. N., in the course of a lecture delivered in the Biological Laboratory of the Johns Hopkins University.

Dr. Beyer says: "It is a fairly well-settled question in physiology that the epithelia lining the convoluted tubules of the kidneys are the structures principally concerned in the excretion of the solid constituents of the urine, and that the epithelium lining or covering the glomeruli is the tissue chiefly engaged in the secretion of the watery constituents of the urine." On this reasonable basis it is evident that increased glandular function is not due to increased blood pressure, but may be readily accounted for on the assumption of cellular activity, due to the influence of the remedy upon the epithelial lining of the convoluted tubules, and that lining or covering the glomeruli. As additional proof of the proposition, I may quote from Dr. Beyer's exceptionally interesting lecture: "Dr. von Schröder, of Strasburg, Germany, in a beautiful series of experiments, has succeeded in conclusively demonstrating, at least to my mind, the fact that caffeine, injected into the circulation, gives rise to a much increased flow of normal urine." As

the writer believes that caffeine lowers blood pressure, it would appear to be unnecessary to pursue the subject farther, and I shall therefore confine myself to a brief report of several cases in which this remedy has done good service:

Case I.—Three years ago I saw Mrs. K. for the first time. The occasion for consulting a physician was continued bleeding at the nose, a circumstance which had occurred previously, but had not been sufficient to cause the family any alarm. The patient was then aged 73, and was rather frail in appearance, and had withal a very unsatisfactory cardiac action; but, aside from being weak and short of breath at times, she had but little trouble. There were found valvular changes together with indications of mitral regurgitation, while the condition of the pulse pointed to senile degeneration. With the exception of slight attacks of indisposition from time to time, she did very well until during the past winter, when there appeared symptoms of a general breakdown, and shortly thereafter œdema of the lower extremities began, which, of course, caused me to give to the friends and relatives an unfavorable prognosis. Up to this time various remedies had been tried in vain with a view to improve the condition of the heart. Digitalis had been tried cautiously, but the contra-indications for its exhibition were so decided that it was discontinued, and convallaria adopted in its stead. Soon, however, it was found that convallaria was not likely to be of any permanent benefit, and small doses of nux vomica were substituted, and with apparent improvement. It was found that the heart did not intermit so often under the administration of nux vomica as it did with either of the other remedies, of which digitalis proved the least beneficial, and caused the most alarming symptoms, amounting almost to syncope. The doses of nux vomica in this case were quite small, and not too frequently repeated; the fluid extract being used, well diluted with water, and as an additional safeguard small doses of belladonna were combined with it. For a portion of the time that the nux vomica was taken, small doses of atropine (gr. 1-200) were also taken, but not all of the time, and I had therefore an excellent opportunity of witnessing the specific effects of each of the three remedies. It was found that the addition of the atropine increased the patient's feeling of well-being; but during all this time my patient was perceptibly sinking, and if any change could be made for the better, it was immediately demanded. It was then

that I decided to try *strophanthus*, a remedy with which I was but slightly familiar at that time, having used it but once or twice previously, and then only temporarily. The remedy was at that time difficult to obtain; but I was fortunate in procuring a fresh supply, and immediately began its administration, in doses of two drops of the tincture every three or four hours, except when the patient slept. In the course of two days there was an apparent improvement in the condition of the heart, and at the end of the week there was a decided change for the better; but, as a matter of course in a case of this kind, which was hopeless from the beginning, the œdematous condition of the feet and limbs was not overcome. The general condition of the patient was manifestly changed for the better, and the medicine was reduced in frequency, as the indications for its use became less urgent. True, the case terminated fatally; but I am disposed to think that she was more comfortable, was made to feel more natural, and lived many days longer than she otherwise would had it not been for the judicious use of *strophanthus*.

Case II.—Late in the spring of the present year I was called on by a gentleman to see his wife, age 26, whom I found in the last stages of consumption; in fact, she died 12 days from the time I first saw her. She had given birth to her first child about four months previous, but had nursed the baby only a short time, her physician wisely advising her that it would not be prudent to do so. The child was fairly well-nourished, but gave no very encouraging promise of longevity. On my first visit the patient seemed very much taxed for breath, and it was with difficulty that I could take the pulse and temperature. The latter was but slightly above normal, but the cardiac action was so rapid that the best I could do was to make an estimate of one hundred and eighty to the minute, and I had serious doubts as to the probability of her living twenty-four hours. The following morning the temperature was 97.9° Fah., the pulse 144 per minute. The feet and limbs were considerably swollen, the stomach was in an extremely bad condition, and diarrhoea was a symptom which required attention. The respiratory trouble seemed to be the most aggravating of all the other ailments, although the throat came in for its share. Suitable remedies were ordered for the condition of the stomach and bowels, and for the bronchial irritation; and in addition to this she was to take one and one-quarter drops of the tincture of *strophanthus* every

three hours. As a result, the digestion improved, and a few days later she began to expectorate large quantities of muco-purulent material, the breathing became easier, and she felt more comfortable than she had for many days. The temperature never reached much over 100° Fah. in the evening, and was generally below normal in the morning, while the pulse was maintained at about 120 per minute after the first twenty-four hours, and was of good volume. The œdematous condition of the extremities quickly disappeared under this treatment, although no observations were made as to whether or not a larger quantity of water was passed.

The clinical evidence in this case is strongly in favor of the value of *strophanthus*, and although she died from exhaustion, it is a question whether the same or equal benefit could have been secured by the use of any other remedy under the circumstances that existed.

Case III.—A few weeks ago a gentleman, age 82, consulted me on account of swelling of the feet and legs, a condition which had appeared within the preceding few days, and, from his statements, did not seem to be due to exposure, nor to unusual exertion. It was about the close of the late heated term, and his age may have had something to do with it. It should be stated that the gentleman has been subject to rheumatism, and his shoulders are now so stiff that he is unable to dress and undress himself without assistance. The action of the heart was fairly good, but knowing his rheumatic tendency it was not difficult to detect indications of the approach of infirmities incident to old age. The urine was carefully examined every few days, and found to be normal, not even a trace of albumin. The age of the patient and the unfavorable condition of the weather both pointed to rest in the recumbent position and mild treatment, but the cautious use of the remedies indicated for the period of eight or ten days accomplished nothing, and he began to get discouraged. At this time he was placed on the tincture of *strophanthus*, four minims three times daily, and at the expiration of three or four days reported again, this time with his shoes and stockings on. He was greatly rejoiced that he could walk about again, and that the swelling had nearly all disappeared. The medicine was continued, the dose stated above being taken but twice daily, and I am happy to say he made a good recovery.

The foregoing case seems to me to be a characteristic one, in which the value of

strophanthus is fully shown. The heart needed a powerful tonic, the stimulating effect of strophanthus on the kidneys favored diuresis, and with appropriate rest the œdema rapidly disappeared, so that as soon as compensation of the heart was re-established nothing more was needed.

Case IV.—Mrs. L. was suffering from rhus poisoning, caught when out blackberrying on her vacation, but the poison remained for some days latent in the system, and when it did appear it came out with a vengeance. As usual, the ordinary remedies failed. However, the poison was fairly under subjection when choleric diarrhœa set in, and, to cap the climax, she received a cablegram calling her to the bed-side of an invalid relative. All these things naturally produced considerable shock to the nervous system, that was manifested by the irregular and uncertain action of the heart, which intermitted every third beat, a decidedly uncanny condition for one who desired to take the steamer in three days. She was immediately put on strophanthus, four minims three times daily, and the irritability of the bowels having been corrected, a restricted diet was prescribed along with suitable aids to digestion, and at the end of the two days, the cardiac action being regular, and without a break, she was in very good condition and quite ready to take the journey to the steamer.

Remarks.—It seems appropriate to make some observations as to the possible value of strophanthus in various cases which come under the eye of the physician, and the reader will pardon a second allusion to its action as a diuretic. In cases of fever, for instance, when there is great tension, the skin hot and dry, with the urine scanty and high colored, it is surprising how quickly we observe the diuretic action of a small dose of aconite frequently repeated. Yet the free perspiration which follows shows conclusively that the tension has been relieved, a physiological effect in many respects just the opposite of that produced by digitalis. I am aware, of course, that aconite is regarded as a diuretic, and that the claim is put forward that it not only increases the secretion of the watery parts of the urine, but also of the solid parts. But while aconite reduces, digitalis increases tension, showing that strophanthus may be substituted for digitalis as a diuretic when it is desired to avoid increased blood pressure. Probably this effect may be explained by assuming that in such cases there is too much tension, and

that this condition being relieved, compensation is re-established, when cellular activity begins.

Again, it would appear to be a suitable remedy in ordinary cases of cardiac dilatation, or in those cases dependent on diseased conditions, such as the later stages of typhoid fever and pneumonia, in which alcoholic stimulants are indicated. From the investigations thus far made, there are good grounds for believing that it will in many instances be preferable to nux vomica and strychnine, and considering the cumulative action of digitalis, it seems far preferable in most cases to that drug. The danger from digitalis is, first, from the dose being too large, when the heart is arrested in systole; or, second, from small doses being too long continued, causing paralysis of the cardiac muscle, when the organ is arrested in diastole. True, it is claimed by some that there is no cumulative effect from the use of digitalis, and I have never seen it, although I have administered digitalis in doses ranging from one drop of the tincture three times daily to forty drops of the fluid extract at a single dose.

Patients in the later months of pregnancy who suffer from a flabby condition of the cardiac muscle along with œdema of the lower extremities, would no doubt be benefited by the use of strophanthus, but I would not say that the presence of albumin in the urine would not be a contra-indication for its use. As a means of preventing collapse in producing anæsthesia, strophanthus promises to supercede the hypodermatic use of morphine and atropine, and as a remedy to prevent the depressing effects following the use of chloral and the bromides it will readily receive a warm welcome.

4719 Frankford Avenue.

SOCIETY REPORTS.

THE NINTH INTERNATIONAL MEDICAL CONGRESS.

First Day—Monday, September 5, 1887.

The Congress was opened at eleven o'clock in Albaugh's Theatre. Dr. Henry H. Smith, of Philadelphia, chairman of the Executive Committee, called the Congress to order and introduced President Cleveland, who opened the proceedings with a short address. He said:

"I feel that the country should be congratulated to-day upon the presence at our capital of so many of our own citizens and those representing foreign countries who have distinguished themselves in the science of medicine and are devoted to its further progress. My duty on this occasion is a very pleasing and a very brief one. It is simply to declare that the Ninth International Medical Congress is now open for organization and for the transaction of business."

Dr. Smith next proposed for President of the Congress, Dr. N. S. Davis, of Chicago. The motion was adopted unanimously.

President Davis now introduced the Hon. Thomas F. Bayard, Secretary of State, who welcomed the Congress in an elaborate address.

The welcome was responded to by Dr. Wm. Harris Lloyd, Inspector General, R. N., on behalf of Great Britain; Dr. Leon Le Fort, of Paris, on behalf of France; Prof. P. G. Unna, of Hamburg, on the part of Germany; Senator M. Semmola, of Naples, for Italy, and Sir Charles Reyher, of St. Petersburg, representing the Government of Russia. Dr. Unna spoke in German, and Drs. Semmola and Le Fort in French.

President Davis then delivered his opening address.

He first referred to the loss sustained by the profession in the death of Prof. Austin Flint and then passed on to a discussion of the present conditions of medical study and investigation. He advocated the increase and diffusion of knowledge concerning the conditions favorable to the propagation of contagious and infectious diseases and the general principles of the collective investigation of disease. He praised the usefulness of medical societies, and urged the importance of systematic study of meteorological conditions over extended tracts of country and long periods of time. He thought this could be accomplished by the medical societies in different parts of the country. He also thought it would be well to have in every medical society two standing committees, to one of which should be referred for critical examination every communication claiming to embody a new discovery in either the science or art of medicine, and the other should be charged with the work of devising such lines of investigation for developing additional knowledge as require the co-operation of different individuals and perhaps societies and of superintending their efficient execution until crowned with success.

He closed with a congratulation upon the great achievements of the medical profession.

Dr. J. B. Hamilton, Supervising Surgeon General of the United States Marine Hospital service, having been nominated and unanimously elected Secretary General of the Congress, took his place and nominated the gentlemen agreed upon as Vice-Presidents of the Congress, who were elected.

Dr. J. Solis Cohen, of Philadelphia, on the question being put, moved to amend and pointed out the uselessness of appointing to office a number of gentlemen who had no intention of being present. President Davis refused to receive the amendment, stating that it was too late now and that whether the nominees were present or not they had not declined the offices bestowed upon them.

Drs. William B. Atkinson, of Philadelphia, George Byrd Harrison, of Washington, and Henry Bangs, of France, were elected as Associate Secretaries; Dr. F. S. F. Arnold, of New York, as Treasurer; Dr. Richard G. Dunlison, of Philadelphia, as Chairman of the Finance Committee; Dr. Henry H. Smith, of Philadelphia, as Chairman of the Executive Committee; and Dr. A. Y. P. Garnett, of Washington, Chairman Committee on Arrangements.

The following gentlemen were elected presidents of sections: A. B. Arnold, M. D., general medicine; W. T. Briggs, M. D., general surgery; Henry H. Smith, M. D., LL. D., military and naval surgery; De Laskie Miller, M. D., Ph. D., obstetrics; Henry O. Marcy, M. D., gynecology; Traill Green, M. D., LL. D., therapeutics and materia medica; W. H. Pancoast, M. D., anatomy; J. H. Callender, M. D., physiology; A. B. Palmer, M. D., LL. D., pathology; J. Lewis Smith, M. D., diseases of children; J. J. Chisholm, M. D., ophthalmology; S. J. Jones, M. D., LL. D., otology; W. H. Daly, M. D., laryngology; A. R. Robinson, M. D., dermatology and syphilography; Joseph Jones, M. D., public and international hygiene; A. L. Gihon, A. M., M. D., U. S. N., climatology and demography; J. B. Andrews, A. M., M. D., psychological medicine and diseases of the nervous system; Jonathan Taft, M. D., D. D. S., dental and oral surgery.

Secretary General Hamilton then read his report of the organization of the congress and Dr. Garnett announced the social entertainments arranged by the committee.

After this the opening session adjourned.

Second Day, Tuesday, September 6.

The second day of the Ninth International Medical Congress was devoted to scientific work exclusively. No ceremonial similar to that at the opening of the congress will be observed until the close of the session on Saturday. At 10 o'clock this morning Albaugh's Theatre, where the general meetings are held, was so crowded by delegates that many of them were unable to find seats. They were attracted by the fact that Professor Austin Flint, of the Bellevue Hospital Medical College, New York, was to read a paper on "Fever, its Causes, Mechanism and Rational Treatment."

Dr. Flint is a son of the physician of the same name who was elected president of the present congress, and whose death was referred to by President N. S. Davis yesterday. Dr. Flint's elocution is perfect, and his manner of emphasizing points was such as to entirely hold the attention of the audience. This is the more remarkable, as the address was philosophical in its character, following with exactness the chemistry of his subject, and touching upon a number of physiological experiments which must sorely have puzzled some of his hearers from the backwoods.

Dr. Flint began by quoting, "Feed a fever; do not let your patient die of starvation." He then went on to condemn the old plan of depletion and insist on free alimentation. He pointed out that the life of acute disease was usually short and self-limited, and the object of treatment should be to afford sufficient nutritive material to make up for wasted tissue, and so keep the patient alive until the disease had run its course. Dr. Flint entered into a profound discussion on the evolution of animal heat, and continuing his argument proved as the result of previous experiments on his own person that the body in health secreted more water than was ingested.

Professor Flint's Conclusions.

He then dwelt on the application of cold and the uses of antipyrin and antifebrin to cases of fever which might be regarded as typical of internal fevers, such as typhoid, as opposed to sunstroke, and concluded a paper, which seemed to be regarded as a masterly effort, by stating the following propositions:

1. Fever, especially in acute disease, is self-limited. 2. We are as yet unable to destroy directly the morbid organisms which give rise to the continued fevers; all that we can for the present undertake is to modify their action and their powers of development. 3. The production of animal heat

involves the oxidation of fat, resulting in the destruction of tissues and the formation of water. 4. As regards its relation to animal nutrition and the production of animal heat water is to be counted as an excrementitious principle. 5. Fever, as observed in the so-called essential fevers, may be defined as a condition involving an excessive production of heat, with the production and discharge of an excessive amount of carbon, and the production and discharge of excessive amounts of water. 6. The more prominent symptoms of fever are, for the most part, secondary to the high temperature, the increased oxidation, etc. 7. The destruction of excessive heat by the application of external cold and the reduction of temperature by antipyretics, while they do not affect the cause of the fever, are beneficial in their influence to the extent that they modify the symptoms secondary to the pyrexia. 8. During a fever the severity of the symptoms is, in a measure, diminished by the introduction into the system of water. 9. Severity of the symptoms of a fever is in a measure increased by the withholding of water from the system. 10. Alimentation during a fever is mainly difficult on account of the derangement of the digestive organs, and this difficulty is to be met by the introduction of articles easily digested and readily assimilated. 11. In the introduction of the hydro-carbons important factors in the reduction of animal heat are attained; alcohol is the best representative of these principles. 12. Precisely in so far as it produces oxidation in the body, alcohol furnishes matter which is consumed in the excessive production of heat in the body. 13. Alcohol diminishes rather than increases the production of pyrexia. 14. As the oxidation of alcohol necessitates the production of heat, it should be given in such quantity only as will meet the demand of the system for nutrition. The slightest degree of intoxication must be avoided. 15. The great object is to limit and reduce the pyrexia by direct and indirect means, and to place the system in the most favorable condition for recovery after the disease shall have run its course.

The conclusion of the address was greeted with loud applause. Professor Semmola was down on the programme to read the next paper on Bacteriology, but President Davis announced that in order to permit the delegates to give more attention to the work of sections, but one address would be given each day. This action was advisable from another cause—the probability that Dr. A. Luteaud, of Paris, who was to have read an address on

"The Influence of American Gynæcologists on the Development of Gynæcology in Europe," may not be present, while Dr. Neudorfer, of Vienna, whose address on "Military Medicine" was down for Thursday, has not yet put in an appearance.

Attendance on the Sections.

The various sections were fairly well attended in the afternoon, with the notable exception of the important section on medicine, which seems to have been poorly organized. It had no morning session, and several other sections were almost empty in the morning. The programme of the various sections was not arranged beforehand, and there is much consequent annoyance. Many of the delegates preferred sight-seeing during the afternoon, especially as the heat has been intense. The Army Medical Museum attracted many of the foreign delegates, to whom its custodian, Dr. John S. Billings, is well known personally or by reputation, but he has not been seen at any of the meetings of the congress, general or sectional. Dr. A. R. Robinson, of New York, chairman of the section of dermatology, invited some of the more prominent specialists in his section to dine with him at Willard's on Wednesday. This is the only entertainment by an officeholder which has come to notice so far.

Notes from the Sections.

The proceedings of very few sections of the Medical Congress will have greater professional interest than the section of gynæcology, over which Dr. Henry O. Marcy, of Boston, presides. In addition to reading papers in his own section Dr. Marcy contributes to the section of climatology and demography a paper entitled "Western North Carolina as a Health Resort."

Dr. Daly's Address.

Dr. W. H. Daly, of Pittsburg, president of the section of laryngology, in his opening address to his section, after greeting the foreign members, said among other things:

"We ought to congratulate ourselves as laryngologists, in this our second meeting, as an independent section of the International Medical Congress, and endeavor to have the work of this branch of medicine placed in every large medical body as an independent section, as the importance and growing excellence of its literature and valuable practical work deserves."

Some Remarks About Hay Fever.

"When one looks back to the state of laryngology in 1876, and makes a comparison with the present status of it, it becomes a

matter not only of utmost interest, but of satisfaction and pride, to those who have been engaged in its study and advancement, to note what alone its cognate branch, rhinology, has done for the successful and rational treatment of hay fever, which, before the appearance of a paper which I read before the American Laryngological Association in 1881, calling the attention of the profession to some observations I made during a few previous years upon the local predisposing intra-nasal causes of this disease, the sufferers therefrom had spent a rambling sort of life in seeking immunity from what they can now in a large percentage of cases easily get cured permanently and surely, at home, by a proper rational treatment. I desire to say, however, that the lamented Hack and some other able workers in the same field claimed more for the plan of treatment I then advised than I ever did, as I then, in 1880, assumed to postulate. I still find it, after seven years, strongly tenable, viz: 'Whether we are warranted in believing any case of hay asthma purely a neurosis without first eliminating the possible causation due to local, structural, or functional disease in the naso-pharynx.' Therein clearly admitting that a proportion of cases were of the character of neurosis, but a far greater proportion still depended on a chronic intra-nasal disease, upon which the exciting cause, viz, pollen, etc., and other agents act with effect, and, second, without this intrinsic nasal disease the exciting cause is innocuous."

Dr. Daly referred also to the advancement of laryngology and its cognate branches.

The Food of the Soldier.

Dr. Jos. R. Smith, lieutenant-colonel and surgeon, U. S. A., read an interesting paper yesterday afternoon before the section of military and naval surgery and medicine on the "Food of the Soldier." He endeavored to show the difficulties in determining exactly, the least amount of food that will suffice for the soldier in the exigencies of service, and gave the rations of different armies and the diets devised by various observers and experimentors, comparing them and discussing their bearings. He showed that in general they err on the side of amplitude; that soldiers, as regards their demand for food, are to be classed in the category of active laborers; that besides the nutriment the food contains we must also consider cost, facility of transportation, and personal preferences in fixing a diet. He concluded that the soldier's ration should contain about 293 grains of nitrogen and 4,576 grains of

carbon, and that considerable variation in the relative proportions of these elements, as well as in those of the food principles and in the bulk of the food ingested, are consistent with health. He suggested two rations for armies whose mean proportions of nitrogen and carbon are N. 300 grains and C. 4,964 grains. Finally he emphasized the fact that sale, barter, and interchange of food, in practice, always give the soldier suitable variety of food.

Dr. Robinson on American Specialists.

Dr. A. R. Robinson, of New York, President of the section of dermatology and syphilography, gave the opening address.

After referring to the fact that there is no particular centre for dermatological study in America and hence no representative American dermatologist, he said, "returning from his European travels—'speaking a foreign language just as well as his mother tongue'—the would-be specialist is beset by temptations to which he too frequently falls a victim. With more medical journals in the land than are necessary for the publication of papers that repay one for their perusal, there is on one hand a demand for an article on some subject, it matters not what it be, by the editor, and, on the other hand, a desire to publish a paper by the specialist anxious for reputation and notoriety. The medical world at large must know that he is devoting special attention to a particular branch of medical science, and what plan so good as to write an article for a journal and by means of reprints scattered broadcast let the world know your specialty, name and address. A few repetitions of this procedure will, without fail, bring patients to the office and reputation among the mass of general practitioners. Why this latter is a result is not difficult to understand. As already mentioned, the college graduates usually have no knowledge of the so-called special branches, consequently any reprint, although it be only a compilation of previous articles by real workers—and very often they are even very poor compilations—appears to the busy practitioner to contain valuable information, and the author thereof as one having special knowledge of his subject.

"This mode of action is a very serious evil, and must and does bring discredit upon the specialists in that branch as a body. It is to be hoped that the protest that I now enter against this evil will not be in vain, and that in the future only such articles will be published as represent real contributions to the existing knowledge of the subject discussed."

He closed by expressing the hope, in view of past events, "that another International Congress will not be held in America until the profession in this country have shown by their actions a change of heart, and that they are prepared to subject the desire for personal gain to the proper, nobler, and more honorable feeling for the advancement of medical science and the relief of human suffering."

Proposed International Vital Statistics.

Dr. A. L. Gihon, U. S. N., in his address, yesterday afternoon, as president of the section of climatology and demography, referring to the expansion of medical science, said: "The Rome that was built on the seven hills beside the Tiber was but the central sun of that great empire, whose limits were co-extensive with human progress. So the medicine, which rested on the foundations of the seven chairs of the schools of fifty years ago was only the nucleus of that broad realm of science which to-day makes tributary every branch of human knowledge. To the outside world medicine is yet only the mercenary art of healing at so much apiece the maimed, and the halt, and the blind of the human race. It is still an inscrutable mystery to the masses that men who in their eyes are only tinkers of human mechanisms, where sweet bells are jangled out of tune, can really be earnestly striving to prevent these very ills whose coming brings them profit. The recognition of the subjection of human organisms to external influences which sanitary considerations have induced has brought climatological questions into prominence as medical factors—not in the restricted therapeutic sense, which has been so long the only medium through which physicians were ever expected to look, but as active forces in man's economy.

"The effects of climate," he said, "are not to be looked for in the prevalence of specific diseases with well-defined geographic limits. The question of acclimation considered, the climate of the United States unjustly denounced as pernicious, when in fact the most heterogeneous race elements are here being welded on a vast scale into intimate union, as nowhere else on earth."

He submitted to the consideration of the section resolutions declaring that in the opinion of the section "it is important there should be established in every country a national department bureau or commission for the record of vital statistics upon a uniform basis, to include not only accurate returns of births and deaths, but the results of the attentive investigation by government officials

of facts bearing upon the natural history of disease as manifested among men, women, and children separately, especially with regard to climatic and other discoverable causes of the several forms of disease, that necessary preventive measures may be determined and enforced for the preservation of the public health." The Italian government, he said, has already made commendable progress in this direction.

HOSPITAL NOTES.

THORACIC ANEURISM — IMPROVEMENT BY REST AND POTASSIUM IODIDE.

REPORTED BY M. HOWARD FUSSELL, M. D.

In May, 1886, Michael E., 50 years old, carpenter, presented himself at the dispensary with the ready made diagnosis of rheumatism of the right chest and shoulder. Something about the man's appearance attracted my attention, and I stripped him, and found the following condition: Visible pulsation of all of the superficial arteries. Apex beat of the heart one-half inch outside nipple in sixth interspace, and at apex a loud double murmur was heard.

A very slight prominence was noted at the junction of right third rib and sternum, which plainly pulsated. There was dullness over the prominence with a very faint systolic whiff.

to put himself under care in the hospital. This he refused to do, saying he was compelled to work.

He was put on potassium iodide 15 gr. t. d. In a week he returned feeling much relieved from pain.

I did not see him again until the latter part of July, when he presented himself in response to urgent word sent him to call. He was still working, and taking the iodide with almost entire absence of pain. He said he was well. He was again warned and urged to rest, but without avail.

He paid no more visits to the dispensary until July, 1887, over a year from his first visit. He said he had been well all winter, until sometime in January, 1887. When, after a hard day's work, he had excruciating pain in region of the tumor above noted, and it had suddenly grown to almost double its size. It continued to enlarge for about two weeks at the end of which time it appeared to him as large as at present. He was now suffering from extreme dyspnoea, amounting indeed to orthopnoea. A severe distressing cough, of the character peculiar to pressure on the air passage, numbness of right arm and hand, with some loss of power. Severe *pain* in region of tumor. A great prominence could be seen through his clothing in the upper part of his chest.

Since May, 1887, unable to be about his work. The prominence extended from clavicle on right side downward to third rib, and from midsternum to the margin of ribs. It was of dumb bell shape, measuring 5 in. in

He complained of *pain* being in the region of this prominence, and radiating to arm and neck, and made worse by lying on left side. On questioning he acknowledged being short of breath on exertion. There was no oedema of feet, and no difference in pulses or pupils. Voice not changed. He was warned about violent exercise, advised

greatest diameter, $3\frac{1}{2}$ in. over each enlarged end, and 3 in. over the constricted portion. Pulsated markedly, the pulsation being expansile and isochronous with systole of heart. Apex beat of heart in sixth interspace outside nipple, with a double murmur at apex; voice not changed, pupils equal, pulse weaker on right side than left, as markedly shown

by the sphygmographic tracing taken at the time, and shown in the cut.

There was no thrill felt, nor bruit heard over the tumor.

Over the position of right bronchus posteriorly, the breathing both on expiration and inspiration was high-pitched and prolonged, showing evident constriction of that tube. Veins at root of neck much enlarged. As stated, his pain and dyspnoea were the most urgent symptoms. He was again told to rest, and has carried out the instructions fairly well. Was given Potass. Iod. in 20 gr. doses t. d., with result of relieving pain to marked extent.

He still refuses to enter the hospital. The rest, though by no means as absolute as desired, has had a good effect in markedly relieving his breathing. The action of the iodide in relieving the pain leaves nothing to be desired in that direction.

The sudden enlargement of the tumor was doubtless due to a rupture of one or more of the coats, and illustrates not only the danger of violent exercise in cases of suspected aneurism, but also shows that severe lesions of the arteries may take place without an immediately fatal issue.

189 Green Lane.

EDITORIAL DEPARTMENT.

PERISCOPE.

Remarks on Four Cases of Excision of the Tongue.

Dr. A. F. McGill made the following remarks which were suggested by the experience of four cases in which it has been necessary for him to excise the tongue.

These were all under my care in the Leeds Infirmary within a few weeks of one another. They illustrate the advantage that is gained by the performance of a preliminary laryngotomy, and the rapid recovery which follows excision by means of the scissors. The method of operating was the same, with slight modifications, in each case.

(1) Laryngotomy was performed, a tracheotomy tube introduced, and a sponge attached to a piece of tape pressed well back into the upper part of the pharynx. The advantages of a preliminary opening into the windpipe are so evident to any one who has operated in the cavity of the mouth with and without this procedure, that it is unnecessary to insist on it. It is however, I believe, more usual for surgeons to open the trachea than to perform laryngotomy. The latter operation has, in my opinion, the advantage that it is much more easily done, and that the resulting wound heals up much more quickly and leaves less scar. The sponge in the pharynx is in every way more satisfactory than the plugging of the trachea with Trendelenberg's tampon. It blocks up both the passage into the trachea and also into the œsophagus, and thus prevents the passage of blood into the stomach, and consequently the unpleasant and perhaps

serious vomiting which blood in the stomach is apt to cause. The anæsthetic can be as easily administered without as with the tampon.

(2) To secure a good illumination of the cavity of the mouth, the position of the patient is changed, the head being raised and flexed instead of depressed and extended as it was during the performance of laryngotomy. Two cheek retractors are placed in the angles of the mouth, and secured by tapes tied at the back of the head. A gag is next placed between the molar teeth on one side, and opened to the full extent. The cheek retractors are of great use, because if the gag is used without them the width of the mouth is diminished instead of being increased, as is required.

(3) The tongue is next secured by a stout ligature passed through it, and is removed with scissors, as recommended by Mr. Whitehead. The frænum and mucous membrane being first divided, the muscles attached to its under surface and the various arteries are cut through. The arteries can be secured with great ease, and this having been done, as much or as little of the tongue can be removed as the peculiarities of the case require. The operation is one of such extreme simplicity that it is hard to understand why many surgeons still recommend the use of the *ecraseur*. The amount of blood lost is usually trifling, and never excessive or dangerous. It is seldom necessary to pass a stitch through the stump of the tongue and tie it to the teeth, as recommended by many authors, for the simple reason that it is generally advisable to remove the organ so far back that no stump is left.

(4) The after treatment is of great importance. The wound is filled with iodoform, which is rubbed thoroughly into all its interstices; it is then plugged with carbolic gauze, the meshes of which are filled with iodoform. The sponge in the pharynx is not removed till all possible oozing has stopped—usually in six or eight hours. The tracheotomy tube is taken out in about twenty-four hours. The patient is, if necessary, fed with nutrient enemata and suppositories, but soon takes liquid nourishment out of a feeding cup, having a piece of india-rubber tubing attached to its mouth. The gauze in the mouth is changed twice daily for three or four days, when it is discontinued, and a gargle of permanganate of potash is kept by the side of the patient, who uses it as often as he feels inclined. He is usually sitting up out of bed within a week, and not unfrequently leaves the hospital in a fortnight. The following are short notes of the cases referred to above:

CASE I.—J. W., aged 69. Epithelioma, involving the right half of the tongue, but not extending over the floor of the mouth; duration of disease, three months. He has been a very great smoker, using clay pipes.

10th Feb.—Operation performed as described above.

4th March—Left the hospital with wound healed.

CASE II.—J. R., aged 57. Epithelioma of right side of the tongue, involving the floor of the mouth and the side of the lower jaw; disease first noticed two months ago, and is now rapidly spreading.

4th Feb.—It being necessary to remove a portion of the lower jaw and floor of the mouth in addition to the tongue, the operation was modified. An incision was made from the angle of the mouth outwards as far as the masseter muscle. The lower jaw was next divided in front and behind the molar teeth, and the included portion was removed with all diseased structures as far as the tongue. The tongue was then removed in the usual manner. During the operation there was considerable hemorrhage, and the advantage of the preliminary laryngotomy was well demonstrated.

On 15th Feb., a fortnight after operation, the patient was made an out-patient, with the wounds nearly closed.

CASE III.—W. J. S., aged 53; admitted with a deep epitheliomatous ulcer, involving the greater portion of the anterior part of the tongue, and localized to it. Disease first noticed four months ago. Has been a great

smoker, smoking more than half a pound of tobacco every week for many years past.

10th Feb.—Operation; stump of mucous membrane secured to teeth.

19th Feb.—Discharged, with the wound healed.

CASE IV.—J. S., aged 68. Extensive disease, involving the whole of the tongue, and extending almost to the epiglottis. There is much difficulty in swallowing, he being unable to take solids. Disease of four months' duration.

17th March—Operation; bleeding slight, only one vessel ligatured. Left the hospital with wound rapidly healing on 28th March. —*Edinburgh Med. Journal*, August, 1887.

Pachydermia Laryngis.

With reference to the case of the Crown Prince of Germany, Professor Virchow read a paper before the Berlin Medical Society, on July 27th, on the disease which he terms pachydermia laryngis. After pointing out the mode in which the squamous epithelium extends from the pharynx to the vocal cords and its distribution in the larynx, he refers to the two conditions which he groups under the term pachydermia, these conditions being more or less allied to chronic inflammation. In both a greater or less amount of squamous epithelium is formed, the result in the one case being a flat, diffuse swelling of a great part of the surface towards the posterior end of the vocal chords, and the other a formation of warty growths—what are commonly known as papillomata, and usually situated towards the anterior ends of the cords. In these the hypertrophy of the epithelium is the chief element, the elongation of the papillæ being, according to Professor Virchow, a secondary process. The latter he terms pachydermia verrucosa. The following is the point on which he lays stress, as distinguishing these affections from epithelioma. He looks on all the cases as simple, local, and only superficially hyperplastic, in which he finds a sharp line of distinction at the base of the epithelial growth, separating it from the fibrous tissue beneath. Where, however, there is any trace of epithelium in the fibrous tissue, he considers the case suspicious. Neither the sessile nor the papillary swellings must show anything of an epithelial character below the borderline between the epithelium and connective tissue. If there is no epithelium beneath this border line, then, whatever may have happened on the surface in the way of papillary outgrowths, fissures, etc., he considers that the disease is local and benign. Appa-

rently the disease in the case which has excited so much interest belongs to the class of pachydermia verrucosa. The possibility of recurrence is great, but experienced laryngologists are convinced that, by continued removal of the growths, it is ultimately possible to get rid of the disease completely.—*Brit. Med. Journ.*, Aug. 13, 1887.

Removal of Large Encysted "Wedgewood" Ball Pessary from Vagina.

Dr. W. J. Beatty read the following interesting account of this case before the Edinburgh Obstetrical Society, 25th of May, 1887:

I have the pleasure of showing you to-day a large ball pessary which had become encysted in the vagina of an old lady, and which I enucleated and removed.

The history is as follows:

Mrs. H., aged 68, consulted me for enlargement in left groin, with an offensive discharge from vagina. She informed me that about sixteen years ago she suffered from falling of the womb, when she was examined by her medical attendant, who advised her to wear a ball pessary to keep the womb in position, and for which purpose he inserted a large wood ball pessary, ordering her to take it out every week and wash it. This she was able to do for about twelve months, but at the end of this period she failed to remove it, as owing (she says) to its greasy condition, it kept slipping from her fingers, and as she had left the town where the doctor lived who inserted it, she felt a delicacy about consulting another medical man, and feeling no inconvenience, she simply syringed out the vagina two or three times a week. She was always able to move the pessary until about six years ago, and has never suffered any inconvenience, except troublesome constipation, and latterly a constant desire to go to stool, until a month ago, when she felt a little pain in the left groin, and found a slight enlargement there, and about a week later had an offensive discharge from the vagina.

On examination I found an enlarged gland in left groin, and in the vagina a large round tumour only slightly moveable, situated to the left and posterior to the wall of the vagina, over which I made an incision and removed the large ball pessary which I now have the pleasure of showing to the members of this Society.

Remarks.—As to the enucleation of the pessary there was little difficulty, but I had considerable difficulty in removing it from the vagina,—the same difficulty, in fact, as my patient herself had, *i. e.*, its greasy con-

dition, and being globular it kept slipping from my fingers, but at last by fixing it against the perineum with the fingers of my right hand. I succeeded in expelling it by external pressure on the perineum with the palm of my left hand.

In conclusion, I may add that since its removal the glandular enlargement has gone, constipation greatly relieved, and the constant desire to go to stool has quite disappeared.

The pessary had become quite soft, and I was able to make a section through it with an ordinary table-knife.—*Edin. Med. Journ.*, August, 1887.

Joint Diseases.

In the *Glasgow Med. Journal* for August 1887, Mr. Knox writes upon the treatment of the inflammatory diseases of joints, of which the following is an abstract:

The lines of treatment followed were, in brief, as follows:—

(1.) *Absolute rest* to the joint in every case. This was secured in most cases by the use of splints, in others by extension. At the same time any flexion or faulty position was remedied under chloroform.

(2.) If the disease was apparently advancing, but no great amount of degeneration had as yet taken place, *counter-irritation* over the joint was employed. For this purpose I used liniment of iodine, fly blisters, or the actual cautery.

(3.) If the disease was comparatively inactive or stationary, *sorbifacients*, especially Scott's dressing, with *pressure* over the joint and a *starch* or *plaster bandage* were used.

(4.) In all cases *cod liver oil* and *iron* were administered in appropriate doses.

(5.) *Nourishing food* of the best possible kinds, especially beef tea or meat soups, with milk. In some cases porter or malt extracts, and even whiskey, were of great benefit even to young children. I have not hesitated to give alcohol at times.

(6.) And, lastly, in suitable weather, I always try to get patients out into the open air and sunshine when they are able to walk, and if I had had little carriages or other conveniences I would have sent out some of those who could not walk, but might have been carried downstairs.

Under such a *regime* it is astonishing how many patients rapidly improve. The pain ceases, and the other symptoms begin to recede. It may take months or even years before a cure is effected, but given the time and the necessary attention, even in very bad cases, I would not despair of an ultimate cure.

Poisoning by Meat.

In May, 1885, about one hundred persons in Chemnitz were taken sick with similar symptoms after eating beef derived from the same source. The meat in question was undoubtedly eaten in a raw state, seasoned generally with salt and pepper, sometimes with the addition of onions and vinegar. In one case in which the meat was roasted, the persons eating it were not taken sick, though meat that was not completely roasted was still poisonous. The meat, as regards color, taste and smell, was not noteworthy, and moreover was completely consumed.

The symptoms took the form of diarrhoea and vomiting. In isolated cases, albuminuria was present. Convalescence was always tedious. One of the patients that died was a child in its first year, which had been well nourished, but by chance had received about a thimbleful of the meat. The pathological anatomy as seen at autopsies was that of beginning typhoid fever. The symptoms of the disease began generally in from ten to twelve hours. Nothing is known as to what the changes in the diseased meat were.—Flinzer, *Centralblatt f. d. med. Wissensch.*, July 23, 1887.

A New Method of Treatment of Erysipelas.

Ducrey remarked at the clinic of Prof. de Amicis, of Naples, upon the very successful treatment of erysipelas by means of injections of corrosive sublimate. Medicines were also employed. The strength used was one-hundredth of one per cent. and more, and injections were made some millimetres from the erysipelatous border and at a distance of three centimetres from each other. Externally, a one per cent. solution is employed upon absorbent cotton. Twice a day the dressings are changed and the injections are repeated, always in different places. By this method there is produced at once over the whole surface, a mild and slight eruption of blisters which mark the healing of the erysipelas, and which are to be treated with boric acid ointment or carron oil.—*Deutsche Med. Central-Zeitung*, July, 1887.

—Porous alum is prepared by evaporating the saturated solution of alum, freed from iron, and just before it is upon the point of crystallizing adding about one-fifth of one per cent. of sodium bicarbonate. The carbonic acid gas produced, when expelled by the heat, renders the mass porous.

BOOK REVIEWS.

“*Neuerungen und Verbesserungen in den Applicationen der Fracturenbehandlung.*” By Dr. Aug. Schreiber, Augsburg.

This monograph is a treatise upon the latest and most improved methods of treating fractures. The author declares that many of these improvements have been unknown to German readers, because original descriptive papers were published in other languages, or, if in German, without illustrative cuts. The author certainly deserves great credit for the completeness with which the subject is presented, and the copiousness with which the work is illustrated. The work is to be commended to any one desiring a complete and yet brief summary of the latest advances in this branch of surgery.

REVIEWS OF PAMPHLETS.

—“*Heredity in Tuberculosis*” was the title of a paper read before the American Climatological Association, May 31st, 1887, by Frank Donaldson, M. D., Baltimore. We are glad to have a reprint of this encouraging paper. We say encouraging, because of the author's belief that the influence of heredity in tuberculosis can be overcome by hygienic measures adapted to special needs. The paper must be read to be justly appreciated. The concluding sentence deserves to be quoted: “*If the prophylactic treatment is thoroughly carried out, the hereditary and the acquired proclivity to phthisis may remain latent and the individual never contract the disease.*”

—Dr. E. C. Seguin's name is well known in connection with keen and critical studies of nervous diseases. The paper before us is called “*A Third Contribution to the Study of Localized Central Lesions,*” and is a reprint of a paper originally printed in the *Journal of Nervous and Mental Disease*, Vol. xiv., June, 1887.

The author presents two cases, the first referring to the face-centre, the second to the leg-centre. Both of these are accompanied by cuts showing the location of the lesions, and by the notes of the autopsies. This paper should be read in connection with Dr. Hurd's article upon Cerebral Localizations in the *REPORTER* for August 27th, 1887.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium,	6.00
Physician's Daily Pocket Record,	1.50
Reporter and Pocket Record,	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut Streets.

P. O. Box, 843.

Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,000 copies.

SPECIAL NOTICE TO SUBSCRIBERS.

Subscribers to the MEDICAL AND SURGICAL REPORTER, who have remitted payments to the former editor, and who do not find upon the wrapper of their journal a correct statement of the time up to which they have paid, are requested to notify the present publishers as soon as convenient.

CHRONIC INCONTINENCE OF URINE OF CHILDHOOD.

The chronic eneuresis which occurs in childhood and early adolescence has not received the attention that it merits. This must be in part because parents are apt to think the child will outgrow the weakness, and in part also because the physician knows that treatment is often ineffectual, and therefore is not desirous of inviting failure by beginning treatment. In about half the cases, the disease is accompanied by some local pathological condition of the penis, or of the rectum. The most frequent local disorder is an adhesion between the glans and prepuce immediately in front of the corona. This varies in degree from a slight adhesion on one side of the glans, to one

encircling the entire glans for about one-eighth to one-quarter of an inch in front of the corona. A greater degree than this is rarely seen. Other less frequent local disturbances, which may also co-exist with the first named, are phimosis, a long pendulous fore-skin, hypospadias, and a rectum impacted with fæces. Boys have been known to go two weeks, and longer, without defecating, and to be constipated to this extent quite regularly.

While local disturbances, varying in kind and degree, are to be met with in most patients, there are a number of cases which present no local manifestation of disease. In some of these the cause must be sought in the urine, and in others in organic or functional disease of the nervous system. Except in those patients who urinate at night under the influence of a dream, which makes them seem to be in the water-closet—except when, in other words, the trouble seems to be psychical—cases of eneuresis of nervous origin are very rebellious to treatment. On the contrary, where there exists a local tangible lesion of the penis or adjacent organs, the prognosis is much better.

In a recent paper before the Medical Society of the District of Columbia, Dr. Adams apparently recommended circumcision in all cases of redundant prepuce, whether this was associated with phimosis or not. Doubtless, his experience has been a large one, or he would not speak so positively. He states that he has only known one instance in which eneuresis persisted after circumcision, and in that case there was reason to suspect stricture of the urethra as a sequel of gonorrhœa. In the course of the past year in a large institution for boys in Philadelphia the result of treatment in twenty-five cases was reported. One of these was a boy (9 years old) who had been circumcised, but, as far as could be determined, without improvement of the eneuresis; while those due to phimosis, or, to speak more exactly, those accompanied by phimosis and adhesions, sometimes with priapism, showed the best results. The adhesions were broken up painlessly by the

previous local application of cocaine, and then the parts were anointed with olive oil. The best internal remedies were belladonna, the bromides, cannabis indica, ergot, strychnia and digitalis. In cases in which constipation was a prominent symptom, cascara sagrada with belladonna proved of greatest service. Their relative merit is fairly indicated by the order given. Suitable combinations of these drugs for special indications will readily suggest themselves to the practitioner.

PNEUMOTHORAX.

Dr. Samuel West, in the Bradshawe lecture delivered before the Royal College of Physicians, August 18, 1887, has given the profession a highly instructive paper, which is manifestly the result of much painstaking labor. He finds that phthisis is the cause of at least 90 per cent. of all cases of pneumothorax. If from the remaining 10 per cent. we exclude cases of gangrene and acute inflammatory, or traumatic lesions of the lungs or pleura, only 2 or 3 per cent. of all the cases are to be accounted for by causes not referable to the lungs. About one case of tracheotomy in every fourteen is followed by pneumothorax.

After insisting upon the fact at which he has arrived as the result of experimental researches, and which he has confirmed by clinical observation, that the lungs can resist a pressure represented by nine inches of mercury, and therefore a pressure greater than can be exerted by voluntary inspiratory efforts or by coughing, he concludes that the occurrence of pneumothorax is presumptive evidence of unsound lungs.

The author then proceeds to study the mechanism of the production of pneumothorax. He accepts as correct the statement that the elastic lung tissue has a tendency to pull the pulmonary pleura away from the parietal pleura, but then asks, why does not collapse of the lung always occur when air enters the pleural cavity? That it does not, is proved by ample clinical and *post-mortem* evidence. Rejecting, then, as untenable the supposition that pneumothorax occurs, but that the air is

promptly re-absorbed, he details an elaborate series of experiments as a result of which he concludes that moist serous surfaces, when accurately approximated, offer a resistance to being pulled asunder considerably greater than the calculated equivalent for the normal elasticity of the lung. "Therefore, pneumothorax can be no longer regarded as a condition to which there is an inherent tendency in the healthy body, but, on the contrary, as a condition brought about by the forcible separation of the pleural surfaces, and in this respect exactly analogous to the distension of the subcutaneous tissue, which occurs in surgical emphysema; and, considering the frequency of subcutaneous emphysema, and the rarity of pneumothorax in simple fracture of the ribs, it would seem to follow as a corollary that the force required to distend the subcutaneous tissue must be less than that required to separate the layers of the pleura. Pneumothorax, therefore, so far from being, as it is commonly regarded, a passive process, and inspiratory in origin, is really expiratory in its initial stage, and requires an active force to produce it; and surgical emphysema, so far from implying, as Fagge asserts, the necessary antecedence of pneumothorax, may in reality be a protection against it, the air making its way in the direction of least resistance beneath the skin rather than between the pleural surfaces."

It is manifest, that when compression of the lung has once taken place, a certain force will be requisite to produce expansion again. How is this brought about? If fluid is contained in the pleural cavities, it may be removed by the pump-like action of respiration upon the lymphatics of the pleura; by being squeezed through the lung, and then removed by expectoration or absorption; or by absorption from the pleural cavity itself.

With reference to the removal of gases from the pleural cavity, there are three forces to be considered: diffusion, simple absorption, and absorption aided by chemical combination. As the rapidity of interchange of gases is great, it is probable that the force exercised may be far greater than is required for the expansion of the lung.

The prognosis of pneumothorax is unfavorable; about 90 per cent. of the author's cases died in the first month. When recovery takes place, it is in one of two ways: either by the gradual conversion of the pneumothorax into hydrothorax, or by the simple disappearance of the air. The mechanism of these processes is indicated above.

PYREXIA AND FEVER.

Before the thermometer came into use as an instrument for detecting changes of bodily temperature, fever was commonly looked upon by clinical observers as a complex of symptoms, among which quickened pulse and respiration held the most important places. Since clinical thermometry has come into general use, there has been an increasing disposition to regard pyrexia as the chief, and, according to some, the only evidence of fever, while acceleration of pulse and respiration are looked upon as results. There is danger of going too far in this matter. In some diseases, such as peritonitis, diphtheria, and meningitis (according to Fagge), there may be severe, and even fatal inflammation without pyrexia, though the pulse is often quickened. If we allow ourselves to believe absence of pyrexia to be evidence of the absence of severe disease, we will in a few cases fall into dangerous error. On the other hand, it is a matter of common observation, that children and those of an impressionable or neurotic disposition may have great pyrexia without serious disease.

With reference to the latter point, some recent experiments of Dr. Ott, of Easton, are of great interest. He has found that puncture of the brain in three points will cause fever. These points are respectively: the parts of the brain about the corpus striatum, the anterior inner end of the thalamus, and the point between the optic thalamus and the corpus striatum, near the median line, puncture of which, according to Schiff, induces a peculiar cry. Dr. Ott regards the function of this heat centre as inhibitory. It has long been noticed that there is in some diseases a sudden and un-

controllable rise of temperature, and the existence of a heat controlling centre, paralysis of which permitted this hyperpyrexia, was therefore inferred. It is not likely that pyrexia of nervous origin will be found accompanied by such emaciation as results from inflammatory fever.

Another point that it is well to bear in mind is that there is a disposition on the part of some writers to return to the old Hippocratic idea of pyrexia, and regard it, in septic and inflammatory diseases, as a conservative process by which nature gets rid of noxious matters in the blood. Fagge, who is an exponent of this view, refers to the fact that micro-organisms cannot survive when the temperature is raised above a certain point. Fagge is probably correct, at least in part. Certainly one cannot fail to be impressed with the occurrence of an apyretic crisis in pneumonia, sometime before the pulmonary consolidation has cleared up.

NOTES AND COMMENTS.

Stenocarpine.

Dr. Knapp sums up the results of experiments with the new local anæsthetic, Stenocarpine, as follows:

From the preceding and Dr. Claiborne's observations, it follows that Drs. Goodman and Seward have presented us with a new local anæsthetic that is very similar to cocaine, chiefly differing from it by its more powerful and lasting mydriatic property. This difference determines its range of applicability.

1. Everywhere, when dilatation of the pupil is desirable—*i. e.*, in all conditions that have a tendency to *congestion and inflammation of the iris*—stenocarpine, either alone or in combination with atropine, is beneficial, and preferable to cocaine.

2. Though its mydriatic effect be less persistent than that of sulphate of atropine, stenocarpine may be used with more advantage when in iritis there is increase of eyeball-tension, a *tendency to glaucoma*, and *when there is great pain*. Further observations have to show whether or not stenocarpine, as other mydriatics, leads to granulations of the conjunctiva. If it does not, it will be very valuable in cases of chronic iritis.

3. Stenocarpine is *inferior to cocaine* when we want anæsthesia without mydriasis, as is the case in the majority of operations—removal of foreign bodies, paracentesis and incision of the cornea, iridectomy, extraction of cataract—more especially when in this operation the iris is spared—operations on the conjunctiva, the lachrymal apparatus, and the eyelids. For an ophthalmoscopic examination, homatropine will be preferable.

4. If we want to be certain of a *complete paralysis of accommodation*, for which stenocarpine is as reliable as sulphate of atropia, stenocarpine deserves preference because its action lasts only half as long.

5. Applied *externally to an unbroken cutis, it produces no anæsthesia*. Observations to the contrary mentioned by Goodman and Claiborne must be owing to peculiar conditions which further experience has to determine.

6. *Small doses* (four drops) *rapidly absorbed* may produce *transient general symptoms*—pallor of the skin, cold perspiration, dizziness, stupor, fainting, nausea, and weakness. The same symptoms are produced by cocaine.

7. Larger doses cause the most *alarming general symptoms*—violent tetanoid convulsions, opisthotonus, dilatation of the pupils, excessive acceleration of pulse and respiration and prostration.

8. *Introduced into the veins*, stenocarpine is the *strongest poison*, causing death almost instantly by arrest of respiration and pulsation.

9. It is certainly dangerous to inject even small quantities into vascular tissues, such as the orbit, for instance; it appears even unsafe to inject it under the skin in quantities exceeding ten minims of a two per cent. solution—*i.e.*, about 0.01 ($\frac{1}{10}$ grain). We should also be on our guard if we apply it to an open wound during the progress of an operation.

10. *The symptoms of poisoning*, as has been seen from the above description, are like those from strychnine. The affinity of the two substances should be further investigated. The chemical tests for the detection of strychnine applied to stenocarpine have proved negative. The reflex excitability from stenocarpine is less than from strychnine, also its toxic effect is considerably less. I instilled into the eyes of a rabbit four drops, and into one eye of another two drops of a two per cent. solution of nitrate of strychnine. Both animals died from tetanoid convulsions in ten minutes. Ten and fifteen minims of a two per cent. solu-

tion of cocaine injected into the orbits of rabbits had no general effect.

The alkaloid stenocarpine was separated by Dr. Seward from the leaves of a tree growing in Louisiana, called the "Tear Blanket Tree." From its likeness to the *Acacia stenocarpa* he dubbed it stenocarpine.—*The Med. Record*, August 13, 1887.

Removal of Right Half of Lower Jaw by Slow Enucleation.

DR. JOSEPH W. HOWE sent a patient to the meeting of the N. Y. Path. Soc. (June 8, 1887), with the following history: Thomas R., 23 years of age, was admitted to St. Francis Hospital with the following symptoms: On October 4 he received a severe blow on the under surface of the chin, which exposed the bone. The wound was sewed up at St. Luke's Hospital, but failed to unite. The jaw afterward became very much swollen and painful, and he sought admission to St. Francis Hospital. Dr. Howe made an examination in the early part of November, and found an extensive swelling extending from the symphysis to the posterior part of the ramus of the jaw on the right side, and a small hole running up under the chin behind the jaw, which led to the dead bone. The teeth on the affected side were loosened, and the alveolar process stripped bare and rough and bathed in pus. Pressure on the outside, over the jaw, forced a quantity of pus out, both from between the periosteum and bone and external to the periosteum. The periosteum was separated along the upper line of the jaw back to the ramus, and in some parts had been completely destroyed. The lower teeth were removed from the jaw the following day, and a portion of the periosteum separated. This process of separating the periosteum from the bone was repeated at intervals for several weeks, while the parts were thoroughly cleaned and the patient's general health was kept up by tonics and stimulants. With the stripping of the bone, the periosteum gradually thickened so as to increase the swelling on the affected side. Three weeks previous to the first operation, he made a careful examination under ether, and separated the greater portion of the periosteum and other tissues from the bone. Pieces of lint steeped in carbolic acid and glycerine were placed on each side of the dead jaw, and the patient was allowed to return to the ward. More swelling and fever followed the operation. On the following Monday he completed the operation, removing the last attachment at the symphysis and pulling out the diseased jaw, leaving be-

hind a good basis for a new jaw in the ossifying periosteum. The slow enucleation of a diseased jaw is a comparatively simple process; very little force and very little cutting are required to remove it. The patient has now a new jaw, which has grown from the old periosteum.—*Med. Record*, Aug. 20, 1887.

Methods of Treatment of Prostatitis, with Especial Reference to Hypertrophy of the Prostate.

Among the different forms of prostatitis, Dr. Fischer of Munich (*Centralblatt für Chirurgie*, No. 3, 1887,) distinguishes that of youth, in which the genitals are over-used (*i. e.*, misused) from that of older individuals. The first always appears as an acute affection, and at times violent in its onset, with high fever, rigors, and even sopor, until the abscess in the urethra bursts, either spontaneously or from attempts at catheterization. Its cyclical course lasts about eight days, and repeats itself after a time. Often for many years one attack follows another in the same way, and finally ends in a cure. Occasionally, however, it passes into a chronic inflammation, with hypertrophy. The more chronic form in older people begins usually with catarrh of the gland, prostatorrhœa, and leads slowly to hypertrophy. According to Nussbaum, it is very characteristic of the affection that when the catheter can not be used, the bladder may only be emptied when the body is placed in a peculiar position, and indeed the position of the body which renders this possible, does not remain the same, but must be changed from time to time to effect the same result. We pass over here the well-known resulting conditions, and point out only the not infrequent occurrence of abscesses. During the treatment of prostatitis in its acute stage, after the regular course of treatment and along with the ordinary after-treatment with iodine and bromine mineral waters, Nussbaum has used the cold ascending douche with great success; a treatment which, in chronic prostatitis and hypertrophy of the prostate, even in cases of long standing, is followed by the best results. Occasionally, among the better class of patients, this treatment may be advantageously combined with brine and sea baths either as full or sitz baths. He disapproves of all methods of treatment which have for their object the forcible dilatation of the narrowed portion of the urethra or the destruction of the gland, as well as all operations for extirpating the prostate through the rectum. Bottini's galvano-caustic treatment is, on the other hand, approved by

Nussbaum, although the difficulties of the operation do not favor its employment. Notwithstanding the untoward results of parenchymatous iodine injections, Iverson's subcutaneous injections of ergotine are thought to deserve careful attention. It is not advised to make an opening of a prostatic abscess from the urethra because of the danger of making a false passage in catheterizing. The incision through the rectum or the perinæum deserves also the preference over puncture with a trocar. Maas's recommendation to divide the sphincter ani in severe cases is worthy of attention because of the opportunity thus given of applying antiseptic washes.

When there is retention of urine in consequence of hypertrophy of the prostate and the various methods of catheterization have been tried without success, the author recommends, according to Nussbaum's method, the puncture above the symphysis pubis, with the subsequent introduction of a Nélaton's catheter, and with antiseptic washing out in preference to the puncture for aspiration, in which latter washing out is not possible—a very important procedure, and one which ought frequently to be done. According to the author's observations, he has often succeeded, directly after the first operation, in introducing the catheter through the urethra; when, after the cure of the cystitis and the removal of the resulting inflammatory products, the prostate rapidly decreases in size, and the fistulæ are also soon cured.—*Journal of Cutaneous and Genito-urinary Dis.*, Aug. 1887.

Mud Poisoning on the Legs of Cattle Like the Western Black Leg.

The mud from creeks and pond holes gets in between the toes and irritates the skin, and also on the legs and inflames the skin. In a short time the skin will crack and then the mud and flies will cause the inflammation to become very severe and the cattle can hardly walk. The mud in the bottom of water holes and quagmires becomes poisonous with the decay of vegetation and the presence of the gases which fill the earth. The cattle should be kept out of the holes and their legs be washed with soap suds and smeared with salted grease. When the trouble has gone so far that the poison has been absorbed into the system then the animal should have doses of physic for a week or two and be fed oil meal or some other mucilaginous food. The physic should not purge but should keep the bowels loose.—*Farm. J.*, Sept. 1, 1887.

On the Treatment of Gout.

I have seen patients with albuminous urine and heavily loaded blood, apparently groaning under the weight of accumulated waste, die quickly and directly after the withdrawal or reduction of an accustomed supply of food and stimulants, although presumably both were in excess. I make it a rule, therefore, never to cut off any food or drink until the blood has been unloaded by elimination, and it is shown by clear and conclusive evidence that the food and stimulants habitually taken are not necessary in the particular case under observation, after a free outlet of nitrogenous waste and excess has been established. Meanwhile direct chemical treatment is adopted with a view to rid the blood of its nitrogenous burden.

The principal of this treatment is the elimination of uric acid. I venture to differ, though with much respect, from the received authorities on the treatment of gout. I do not give alkalies to neutralize the acidity of the urine, nor do I offer the uric acid in the blood a base such as soda or potash with which to combine. It is, I think, preferable to break it away from the combinations into which it has already entered, and while providing a large quantity of fluid to wash it out of the blood, and through the kidney in solution, to avoid increasing, but on the contrary try rather to diminish the deposits of urate of sodium with which the attack of gout is associated. With this view I give iodine in the form of a tincture with glycerine; an infusion of serpentaria, or pure water, being employed to dilute it. The clinical effects of this treatment are almost uniformly these: the strength is maintained, while the irritative fever is lessened, the pain is relieved, and the swelling is reduced. These happy results are, I believe, brought about by the simple process of rapidly ridding the blood of the uric acid, together with other products of imperfect metabolism. The urine becomes increasingly acid by reason chiefly of the elimination of oxalic acid with the uric, and it is either increased in quantity, or is more dense, without being increased, rapidly throwing down a shower of uric crystals. Under the most favorable conditions the total quantity of urine passed is simply immense, and its burden of uric acid is *proportionally* (i. e., to the total quantity excreted,) increased. The primary effect of its increasing the acidity of the urine lasts four or five hours only, and side by side with it there is an amelioration of the symptoms. I have in no instance, for some years past, in fact since I have treated gout

by this directly chemical method, had occasion to use colchicum or any sedative. The relief afforded has been immediate and effective. The only cases which have baffled my endeavor have been those in which morphia had been largely used previously to the attack or exhibited in it. I cannot tell why this effect should be produced by morphia, but it undoubtedly seems to antagonize the treatment and render it useless. The *rational* of the use of iodine in gout is, I believe, as above stated, in the main a separation of the uric acid from its bases, but I am not sure that there is not also some destruction of the uric acid affected by its agency. As these are simply notes on treatment, I will not attempt the discussion of the chemical question this conjecture would raise. Suffice it to say that the practical results gained by the method in my experience, at least, surpass those attainable by other procedure, and, which is of considerable moment, the patient not only suffers less than usual during his attack, but his convalescence is shorter and the paroxysm is not so soon followed by another, when it is thus treated. Moreover in the interval, he is not compelled to live the life of an invalid, and by the occasional use of the same remedies the deposits in and around his joints—which must, I think, be always regarded as unexploded shells left from previous wars—are progressively broken up and removed by the action of the iodine circulating in the blood. By a careful examination of the urine from time to time for quantity, specific gravity, acidity, urea, and uric acid, a fairly precise knowledge of the progress of the case may be obtained; and after watching a considerable number of cases for some years, I cannot doubt that the method of treatment adopted is, on the whole, the most satisfactory.—DR. MORTIMER GRANVILLE, *Braithwaite's Retrospect*, July, 1887.

—Owing to the transference of Prof. G. Baumgarten from the chair of Physiology in the St. Louis Medical College to that of special Pathology and Therapeutics, the duties of the former position will be fulfilled by Dr. Wm. Townsend Porter, with the title of assistant professor. Dr. Porter is a most meritorious man and conscientious worker, and will undoubtedly perform the duties of the chair with diligence. During the last year he has been pursuing physiological studies in the laboratories of the University of Pennsylvania and the Johns Hopkins University.—*Weekly Med. Rev.*, August 20, 1887.

Spontaneous Absorption in the Empyema of Children; the Relative Advantages of Aspiration and Early Incision in Children.

Dr. L. Emmett Holt read a paper upon this subject before the N. Y. Academy of Medicine, May 19, 1887, in which he discussed these two points. The prognosis was much better in children than in adults. This depended upon the fact that the ætiology differed at the earlier and later ages. In adults empyema occurred commonly in tuberculosis, which was not the case in children. Spontaneous absorption took place very rarely; he had been able to find but two recorded cases in which the diagnosis had been proved by the withdrawal of some of the pus. It was evident that in children the chances of recovery from empyema by nature's unaided effort was not great. One of the conditions of cure of an abscess, wherever located, was that the walls should come in contact. This was accomplished in the chest by expansion of the lung, for the outer wall was unyielding. The more rapidly and completely the expansion took place, the quicker the recovery. The indications for treatment were to get rid of the pus by the easiest, safest, and most thorough means as early as possible. He would discuss only aspiration and incision with drainage. Puncture with the trocar and siphon drainage was an incomplete form of drainage, and could not easily be carried out in children. The advantages of aspiration were: its simplicity; with ordinary skill and clean needles, its freedom from danger; the fact that the fluid was not removed rapidly, so that gradual expansion of the compressed lung was favored; the absence of any necessity of confinement to bed or of general anæsthesia; and the cure of many cases by it alone, the fluid after one or two aspirations becoming serous and then being absorbed rapidly. But there were some very obvious objections. Not all the fluid could be removed. One sac might be emptied when another was not touched, whereas by incision and insertion of the finger the septa could be broken down. There were also certain cases in which aspiration was not applicable, as where the pus was of a septic nature, or associated with gangrene of the lung, or contained much clot.

The advantages of incision and drainage were pointed out, and then the use of general anæsthetics was considered. The author had twice known rupture to take place in a bronchus while the patient was unconscious, and death to result from suffocation. Both these cases were in adults. But local anæ-

sthesia could be relied upon. It seemed that cocaine would suffice. The results of incision and drainage had been much improved in the recent statistics. He had collected eighty cases treated by antiseptic incision in which the duration of the discharge had been given. In five cases it was four months or over; in the remainder it averaged six weeks. In twenty-one cases, mostly cases of early operation, the duration was a month or less.

The author drew the following conclusions: 1. All methods of treatment of empyema in children yielded better results than in adults. 2. It was never justifiable to leave a case to nature. 3. Aspiration held out a reasonable prospect of success in cases of localized empyema, but a very slender one when the exudation was general. 4. If, after two aspirations at the most, pus accumulated again, showing no tendency to change to serous effusion, aspiration should not be persisted in. 5. In a case of large effusion, one aspiration might be done as a preliminary to a cutting operation. In all other cases a free incision should be made as early as possible.

In the discussion which followed the reading of the paper, Dr. A. L. Loomis said that he had been accustomed to regard the pleurisy of children as a very different affair from that of adults. Acute suppurative pleurisy in children was of a very common occurrence. In fact, whenever he found fluid in the chest of a child, the chest becoming pretty rapidly filled, he was pretty certain that it was purulent, not sero-fibrinous. According to his observation, suppurative pleurisy in the adult was in the majority of cases a dangerous thing, and rather rapidly dangerous. He had come to recognize it as infectious pleurisy in almost all instances. He had rarely found acute suppurative pleurisy in the adult without also finding some acute pneumonic disease in the opposite lung. He had seen the pleural cavity become filled with pus to its utmost capacity within twenty-four hours. And it seemed that the constitutional disturbance and fever went on in the same degree after removal of the fluid as before. We had to contend at this time with an acute disease which could not be removed simply by withdrawing the products of inflammation. But after the subsidence of the acute process, when the case became one of simple empyema, the chances of effecting a cure were decidedly in favor of treatment by incision. He thought the incision was of no benefit at the beginning of an acute suppurative pleurisy. He believed the cases were at the start fibrinous pleurisy, but with-

in twenty-four hours afterward the chest cavity might be filled with pus.—*N. Y. Med. J.*, Aug. 27, 1887.

Dr. Kraske's Method of Treating Erysipelas.

Dr. Classen describes the plan of treatment which was found to be so successful in a recent epidemic of erysipelas. A number of incisions were made into the affected part, so that one-half their length passed beyond the inflammatory region into the surrounding healthy skin. These were crossed very acutely at $\frac{1}{2}$ cm.'s distance by another series of incisions, so that the points of crossing were close to the edge of the erysipelas. If a part of the trunk, as, for example, the mamma, was affected, the whole portion was encircled by radiating incisions, crossed very obliquely by others. If the disease attacked an extremity, it was surrounded by a ring of incisions, because experience taught that if a bridge of intact skin were left between the cuts, the inflammation quickly crept along this, and spread extensively about the limb until it was limited by other and more carefully made incisions. The author thinks that although the treatment was applied in his own cases to superficial erysipelas, it is undoubtedly applicable to the deeper parts, the scarifications being then made into the subcutaneous tissue.—*The Med. Chronicle*, Aug., 1887.

Parson's Local Anæsthetic.

Chloroform.....	12 Parts.
Tr. aconite.....	12 "
" capsicum.....	4 "
" pyrethrum.....	2 "
Oil cloves.....	2 "
Camphor.....	2 "

Dissolve the camphor in the chloroform, then add oil of cloves, and then the tinctures.

The venerable Dr. Parsons, in sending this formula for publication, says: "I cannot expect to remain much longer in this world, and I want the profession to know the value of this local anæsthetic."—*The Southern Dental Journal*, July, 1887.

The Question of Consciousness after Decapitation.

Not long ago we referred to certain investigations of this question in France, in the case of the lower animals. In a recent issue of the "*Progrès médical*," M. Paul Regnard and M. Paul Loye give an account of their observations in the case of a criminal be-

headed at Amiens. They concluded that there was no sign of conscious life at the end of two seconds, but, by irritating the cornea, they were able to evoke reflex movements up to the sixth second. The contractions of the cardiac ventricles continued for twenty-five minutes, and those of the auricles for an hour. The death was calm and without agony, contrary to what one of the authors has observed in the lower animals, and was due not to asphyxia, but to an inhibition analogous to that studied by Brown-Séquard in animals that died of the effects of certain irritations of the nervous system.—*N. Y. Med. J.*, July 30, 1887.

CORRESPONDENCE.

A Formula for Lithuria.

EDS. MED. AND SURG. REPORTER:

R	Liq. ammoniæ citrat.....	3	jss
	Sodæ phosphatis.....	3	jss
	Acidi salicylic.....	3	jss
	Ferri pyrophosphati.....	3	ij
	Glycerini.....	3	ij
	Elixir aurantii.....	3	vj
	Aquæ q. s. ad.....	3	vij

S.—Mix in the order of the formula, shake well, and give a tablespoonful every 3 or 4 hours.

I have found no prescription superior to this in cases of lithuria, and in uric acid diatheses attended with gouty and rheumatic symptoms; and under such circumstances, the mixture is much improved by the addition, to each dose, of twenty drops of wine of colchicum. In combination with drachm doses of either of the fluid extracts of pariera brava, or dog grass, it has served me well in chronic cystitis, gonorrhœa and leucorrhœa. The fluid ext. of pichi, in suitable doses, has also, proved an excellent addition to the formula in the treatment of mucus discharges from the urinary organs.

J. B. JOHNSON, M. D.

Washington City, D. C.

—A complimentary dinner was given, under the auspices of the German Medical Society, of Philadelphia, to Dr. Carl Seiler upon his return from Europe, at the St. George hotel, on Friday evening, Sept. 2.

—It is asserted by an exchange that many thousand tons of pea-nuts are imported into the ports of France annually for the manufacture of oil, and the residue, after the oil is expressed, is used for adulterating cocoa in the preparation of chocolate confections.

NEWS AND MISCELLANY.

A Move in the Right Direction.

The announcement recently made by the College of Physicians and Surgeons of New York to the effect that, beginning with the session of 1888-9, and thereafter, it will require preliminary examination of matriculants who do not hold diplomas or certificates from recognized colleges or schools of science, should be hailed with satisfaction by the profession.

If anything is needed at the present time it is a reform in our present system of medical education. Under the exercise of old custom students of any and every grade of preliminary training have been freely admitted to courses of medical instruction by nearly every medical school in this country. With absolutely no safeguards thrown around the study of medicine, it is not a matter of surprise that the ranks of the profession of medicine are filled with ignorant, illiterate and incompetent men. The extent of this ignorance and illiteracy can only be appreciated by those who have the means of coming into contact with large numbers of medical practitioners. To the medical editor these revelations of incompetency are frequent and appalling. We are frequently in receipt of communications from medical practitioners which display such illiteracy and ignorance that we cannot but regret that their prior general training was so utterly deficient as to defeat their usefulness in professional work to a very great extent. Whilst we admit that an occasional man may make an excellent practitioner with a very small knowledge of the language he speaks, this argument will only hold good in such exceptional cases as make it a dangerous precedent. Other things being equal the better preliminary education the medical student has the better is he equipped for the study and practice of his profession. He should at least have a good knowledge of his own language and some acquaintance with Latin and Greek, but especially the former. He should know something of elementary mathematics, including arithmetic, algebra and plain geometry, and should have some acquaintance with general history and modern literature. Those young men who have not enjoyed the advantages of preliminary instruction to the extent here indicated should be discouraged by their preceptors from studying medicine and should be refused admission to our medical schools until they have passed a satisfactory examination on these branches.

The action of the College of Physicians and Surgeons of New York in requiring a preliminary examination is a move in the right direction and we trust that their example will be the means of inducing other schools to adopt this course.—*Maryland Med. Journ.*, August 13, 1887.

An Epidemic of Convulsions.

A curious outbreak of convulsionist's mania, analogous to those which occurred from time to time during the Middle Ages, is reported by a foreign contemporary to have shown itself at Agosta, in the province of Rome. For some weeks past the country people have been laboring under the delusion that the district is under the immediate government of the Evil One, and before retiring to rest they carefully place on the threshold the broom and the salt, which are credited with the power of keeping off evil spirits. Many of the younger women have epileptiform attacks, during which they utter piercing shrieks, and are violently convulsed. So serious had the condition of things become, that the syndic of Agosta found it necessary to inform the Prefect, who sent detachments of soldiers into the district in order to calm the apprehensions of the inhabitants. The contrast between this strictly physical way of dealing with the disease and the more imposing but less effectual religious ceremonies formerly employed must be interesting to historical students. As a natural consequence of this condition of mental perturbation, the country is overrun with quacks who claim to possess the only infallible remedy for the seizures. One of these nostrums, the vendor of which was making a rich harvest from its sale, was found on analysis to consist of earth, snuff and borax. Three medical men who were commissioned to investigate the cause and nature of this extraordinary affection, came to the conclusion that it was an epidemic of hysteria. They examined a number of the sufferers, mostly young women, some of whom were alleged to have vomited nails, horse-shoes, and other equally indigestible substances, while others barked like dogs. Several of them were removed to Rome for treatment in the hospitals there, and measures have been taken to check the spread of the mischief. In a milder degree, this contagious form of hysteria is not infrequent, especially in places where ignorance and superstition favor manifestations of nervous disorder. The worst excesses of popular outbreaks, like

the French Revolution, have been attributed to similar influences, and with every appearance of justice.—*Boston Med. and Surg. Journal*, August 18, 1887.

Female Medical Students.

A humorous piece of versification recently published in a contemporary, describes the pitiable condition of a north country "coach" on being applied to by a female student to give her private lessons in anatomy. The gist of the humor resides in the bashfulness of the grinder, who was eminently desirous of restricting his lessons to things which in his estimation were "consistent wi' propriety." As a joke, the sentiment is commendable, but when it is brought into real life it becomes ridiculous. Men who have studied abroad can bear witness to the fact that it is at least as easy to study anatomy, or any other department of medical education, in the society of female students, with the most perfect propriety, as it is to perform gynæcological or obstetrical operations in an operating theatre with the assistance of the nurses, without any mental qualms. So long as separate courses of study are insisted upon for the two sexes, so long necessarily will a certain amount of diffidence mark the manner of both when they come together in after life. We are, however, ready, to confess that so far as our experience goes, the diffidence has generally been more marked on the part of the male than on that of the female student, and this fact is explained by the latter having schooled themselves to ignore everything not having a scientific bearing. Female medical students do not belong to that category of young ladies, one of whom is reported to have fainted on being told that a man was looking at her with a naked eye.—*Med. Press and Circular*, July 20, 1887.

The Mummy of Sesostris.

The following particulars of the examination of the remains of Ramses II., made by Dr. Maspero at Boula possess a certain interest: "When the bandages were removed, after the lapse of some three thousand years, the body was exposed to view. The summit of the cranium was denuded. The hair, scanty on the temples, was plentiful over the occiput, and was stained of a yellow color. The forehead was low and narrow, the eyebrows prominent, the eyelashes white and thick, the eyes were small and near together, the nose long and thin, and flattened from the pressure of the wrappers. The temples were depressed, and the cheek-bones well

marked; the ears stood out from the side of the head, and were pierced like those of a woman. The mouth was small, the lips thick and fleshy. It was filled with a dark-colored paste, on removing which some friable teeth were visible, which, though worn, were white and well preserved. The beard and moustache appeared to have been allowed to grow only during the last illness or after death, the hairs being about an eighth of an inch long. The skin was of an ochre color, with black stains. Nevertheless the face gave a very fair impression of what it must have been during life, not too intelligent, even rather vulgar, but indicative of pride, obstinacy, and domination. The other parts of the body were not less well preserved than the head, but the desiccation of the soft parts had materially affected their outline. The neck was reduced to the diameter of the vertebral column; the chest was broad and the shoulders high. The arms were crossed over the chest, and the hands were delicate and stained. The wound through which the embalmers had removed the viscera was extensive, and was situated on the left side. The genital organs had been removed with a cutting instrument. The thighs and legs were emaciated; the feet long, thin, and flat. The corpse was evidently that of a robust and vigorous old man."—*Med. Press and Circ*, Aug. 17, 1887.

Counter Prescribing.

If Health Commissioner Dudley finds the time hanging heavy on his hands during these piping days of health and freedom from epidemic and endemic diseases in the city, we sincerely hope he turn his attention to an evil that has been steadily growing in St. Louis and which has become almost universal with a certain class of local druggists. We allude to the habit of counter prescribing, which is indulged in to an extent that is scarcely credible to those who have not examined into the matter. We do not, of course, refer to the administration of well-known remedies in the simpler ailments of life, the recommendation of a cough mixture, diarrhoea remedy or tooth-ache drops; but to the custom of diagnosing and prescribing for almost any and every ailment that is brought to their notice by prospective patients. From long immunity these fellows have, some of them, become so bold that it would seem like an easy matter to fix the offence upon them sufficiently clearly to bring them under the penalties of the law concerning unregistered physicians.—*St. Louis Med. and Surg. Journ.*, Aug., 1887.

Read Medical Journals.

Dr. T. L. Brown writes as follows to the *Med. Advance*, August, 1887: I secured a very important case, many years ago, and through this one case a number of others were brought to me. I never knew until months afterwards how I happened to be selected. It was in this way: One night, at quite a late hour, I was called to see the family of a prominent New Hampshire official, temporarily staying in our town, to whom I was a perfect stranger. After I had discharged myself, and quite a while afterwards, I learned that as soon as this gentleman found that he required a physician, instead of asking the landlord of his hotel, or appealing at some drug store for the name of a doctor, he took a carriage and drove to the house of the postmaster. "I want a doctor," said he. "Tell me which one of the doctors of this city takes the largest number of journals?" The postmaster referred him to me. As the gentleman was leaving the house he said to the postmaster: "A man who takes the journals of his profession is well read and up with the time, and that is the doctor I want to treat me and my family."

Physical Condition of the St. Louis Police Force.

Dr. George Homan, whose eminent capacity to judge and absolute impartiality no one who knows him will doubt for an instant, declared in a paper read before the Medico-Chirurgical Society of this city a few days since, that out of the entire police force of St. Louis, numbering 482 men, rank and file, less than one hundred are physically qualified to stand the strain of emergency duty should they suddenly be called into service. He classifies the force as follows: Superior to good, 3; good, 82; good to fair, 181; fair, 116; fair to doubtful, 40; doubtful, 17; doubtful to unsound, 19; unsound, 12; unsound to bad, 1; bad, 2. Of the nature of the maladies and disabilities found to exist, Dr. Homan says: "While in certain of these affections and conditions the consequences of hard, honest police service were to be seen, in others their occurrence pointed to medical examinations not sufficiently strict, to heedless appointments by those in power, or to intemperance or licentiousness on the part of the person affected." The importance of this subject justifies the publication of this report in full in the secular papers of the city, and the

thanks of the citizens are due to Dr. Homan for the exposé thus made.—*St. Louis Med. and Surg. Journal*, August, 1887.

An Unhappy Mistake.

An occurrence is reported from Paris as deplorable in its way as any of which we have heard of late. Two children were sent to a hospital suffering from variola, both of whom were called Georges. For obvious reasons the parents were forbidden to see them pending treatment and convalescence. One of the children died soon after admission, and the decease having been duly notified to the parents, the interment was proceeded with. After the lapse of some weeks the parents of the survivor were informed that they could fetch their child, but on a messenger being dispatched for this purpose, the identity was disputed, and after some delay it was discovered that the bed-cards had, by some mishap, been changed, and that the child really belonged to the other parents who had been informed that their infant was dead. It is needless to dwell upon the gravity of such a mistake, which could not fail to have caused great and needless pain to both parents. It is greatly to the credit of the hospital administration that this is really the first time that such a case has presented itself, for the system lays itself open to such errors. It has been suggested that in view of the disfigurement caused by diseases such as variola, it would be eminently desirable to provide each patient with a bracelet duly numbered by means of which the identity might be assured. An unworthy attempt has been made to throw the discredit of this regrettable accident on the institution of lay nurses, but it is evidently the fault of the system rather than that of individuals.—*The Med. Press and Circular*, Aug. 17, 1887.

Poison Fangs and Glands of the Mosquito.

The general arrangement of the mouth of the female mosquito is well described by Dimmock on "the mouth-parts of the *Diptera*." The under lip is a large hairy tube, 2 millimetres long, open above, and serving as a sheaf for the piercing apparatus, whilst it is itself terminated by two sensitive labellæ, and by a central lancet like ligule. Within the structure of the sheaf are a large nerve, a pair of longitudinal muscles, and many oblique muscles, two large tracheæ by which air can be admitted (so as to distend the organ as in *Musca*), and long filiform tendons which arise at the base of the sheaf and support the terminal labellæ.

The piercing apparatus is enclosed during rest in a strong-pointed upper-lip (*labrum*) which is grooved inferiorly for their reception, and which along with them is received into the sheath-like under-lip. Within this labrum are the two maxillæ, very sharp and barbed near the tip, and able to play back and forward like saws; also two mandibles, a fine styliform hypopharynx, a delicate sheath for the front segment of the œsophagus, and œsophagus itself. The last named organ is received within the head into a strong box-like pharynx, which is well supplied with muscles and is a suction organ. The pharynx draws in blood (and probably vegetable plasm), which it transmits by the long post-pharyngeal part of the œsophagus to the stomach lying in the abdomen of the insect.

The poison apparatus, which hitherto has been an unknown quantity, is connected with two mandibles. Each mandible has a large funnel-shaped base, into which is inserted the end of a poison-duct. The thickened axis of the mandible is pierced by a fine canal, which opens just below the sharp apex. The structure reminds one of a bee's sting, saving that it is duplicated. We can by pressure drive out some of the contents and observe them issuing at the sub terminal orifice. It is probable that when the lancets pierce an object this fang-like mechanism may, by pressing on its base, automatically discharge a portion of the poison. The poison seems by inflaming the tissues to determine a flow of blood, and also to prevent the coagulation of blood or other proteid. (The blood subsequently coagulates in the mosquito's stomach.)

The poison duct resembles a trachea in being transversely striated, but differs by the uniform diameter of its tubule of about 6 micromillimetres, by the absence of fine ramifications, and by the great thickness of its wall. The two ducts, proceeding one to each mandible, arise by the bifurcation of a common duct in the region of the neck below the œsophagus. Behind this the difficulty of dissection is considerable, as the parts are so small that they cannot be followed with low microscopic power; they are greatly entangled among the large muscles, trachææ, and other furniture of the prothorax, and they are easily torn so as to be lost to the search. I have succeeded, however, by working back from the neck, in spreading out the entire system. The common duct arises from three prothoracic glands all sessile on its lower extremity like the leaves of a trefoil, each supplied with a pre-

current ductlet, the three ductlets meeting at a point so as to form the common duct. The glands are each about one-third of a millimetre in length and one-twenty-fifth in diameter. The two lateral glands are of the usual salivary kind common to insects. The central or azygos gland is entirely different, scarcely lobed, but being a mass of brown evenly distributed granules, with oil-like globules intermingled, its ductule having finer walls than the lateral glands. We may regard this as emphatically the poison gland, but the intermingled products of all three have their only outlet by the common duct, and thence by its two branches to the mandibles, which therefore play the part of "poison-fangs."

Some tentative notes recently given before the American Association involved inaccuracies, which are here rectified and the work completed. Measurements given above are from a small species which may perhaps be identified by its maxillary palps being as long as the maxillæ themselves. They seem to be the same for all the common species.—G. MACLOSKIE, in *Science*, Aug. 26, 1887.

Increasing Danger of Tape-Worm.

In the Texas grazing region, from which has sprung, within the last two decades, the entire stock of range cattle of the western states and territories, the beef tape-worm is a most common occurrence. In fact I do not believe I exaggerate when I say that at least every fifth person is afflicted. The cause of this is that on open ranges the eggs of tape-worm are most easily and widely distributed, and hence the cattle more frequently become infested with cysts. Stall-fed cattle, on the other hand, where the water is usually less subject to contamination, and the food cleaner, are only seldom infected, and hence tape-worm was not so prevalent in regions where the latter were used.

In the last few years, however, the shipment of range-cattle, by means of refrigerator cars, has become the chief beef supply of the East, and the danger and frequency of tape-worm greatly increased. Of course, no one should stop the use of well-cooked meat on this account, but rare and half-cooked meats can easily be avoided.—R. T. H., in *Science*, Aug. 26, 1887.

Almen's Test for Sugar.

Professor Almen, of Upsala, has improved the old bismuth test for sugar. He prepares a solution which is said to have the advantage of remaining unchanged for years, and being at the same time extremely delicate.

It is made by dissolving 8 parts of caustic soda in 100 parts (by weight) of water and adding 4 parts of sodio-potassic tartrate, and two parts of bismuth subnitrate. In testing for sugar in urine any albumen present must be first removed by precipitation by heat and acid. One part of the solution is treated with ten of the urine, when, if sugar is present, the bismuth will be deposited in the metallic state.—*Druggist's Circular and Chemical Gazette*, August, 1887.

Items.

—BLUE INK FOR STAMPS AND PADS.—Dissolve 2 parts of borax in 20 parts of water, heat to boiling, and dissolve in it 2 parts of bleached shellac; separately dissolve 2 parts of gum arabic in 5 parts of water; with the latter solution mix intimately 1 to 2 parts of best ultramarine and add to the shellac solution. Finally, add enough water and a little glycerine, if necessary, to make 25 parts.—*Chem. and Drug.*, July 30, 1887.

A young lady went into a store to purchase a diary, and had about concluded to secure one shown her, when she changed her mind, and said: "I guess I'll take a purse for the diary." An old lady standing near, and who only partially heard the foregoing announcement, went over and said in a loud whisper: "Miss, don't you do it; take blackberry cordial."

LIVING WITH HER HEART SPLIT.—Jane Berry, a colored servant of Dr. Holmes, living between New Brunswick and Cranberry, N. J., died on Thursday, and a post-mortem examination, made by the county physician, is said to show that she had lived eighteen hours after her heart had been severed, to the depth of three quarters of an inch, by the rupture of a blood vessel. The woman was taken suddenly ill on Tuesday.

OBITUARIES.

NATHANIEL ARCHER RANDOLPH, M. D.

Nathaniel Archer Randolph, was born in Philadelphia in 1858; he was tutored by his able mother until he entered Swarthmore College where he prepared for Cornell University. After graduating here he completed his literary studies abroad, and returned to enter upon his medical studies in the University of Pennsylvania. He received his medical degree with honor in 1882, and again visited Europe to engage in professional

study in physiology, therapeutics and the relation of foods to nutrition, a subject in which he made valuable experimental researches. Returning to America he soon became Instructor in Physiology in the Biological Department of the University, and a member of the editorial staff of the *Medical News* and the *American Journal of the Medical Sciences*. His abilities as a teacher were recognized at once, and his able and facile pen made him a valued writer. He became a Fellow of the College of Physicians, a member of the County Medical Society, of the American Philosophical Society, and of the Academy of Natural Sciences, where his attainments in medicine and its allied sciences won the respect of all his colleagues, while his genial nature and his sincere and kindly interest in his fellow-men gained for him the affectionate esteem of all with whom he came in contact. In 1887 he was elected Professor of Hygiene in the University, where his lectures were highly prized and were largely attended by the students, with whom he was a favorite. In May 1887 he assumed, with Dr. Charles W. Dulles, the editorial and general management of the *MEDICAL AND SURGICAL REPORTER* and its allied publications. Here his varied gifts, good judgment and kindly nature had established relations between the readers of the *REPORTER* and himself which promised to increase largely his already large circle of friends. Dr. Randolph, as a writer, more than do many, dipped his pen, not only in ink, but in his own personality; and the place and influence of the personal element in journalism was a subject of great interest to him.

His last scientific research was a study of the irradiation of motor impulses, contributed to the College of Physicians in March, 1887. He had in mind the establishment at the University of a laboratory for hygiene, and had labored faithfully for the accomplishment of this project. During the winter preceding his death he had made a careful study of house sanitation, visiting for this purpose the best appointed new buildings in the city; and his opinion had been sought on matters of practical hygiene.

To his intimate friends, Dr. Randolph had mentioned the existence of a heart trouble which had annoyed him at times, but he never relaxed his performance of duty, and the heated term saw him faithful in his office. It is supposed that anxieties of various kinds, his unremitting labors, and the heat of the terrible season just passed had rendered heart failure possible in one who was ordinarily in the best health. On the

day of his death, Dr. Randolph and his wife were bathing in the sea at Longport, N. J., when a wave larger than its fellows broke over them, and carried them off their feet. Dr. Randolph made an attempt to support and rescue his wife from danger, and while thus engaged suddenly threw up his hands, and sank. His wife was now helpless, and had to be rescued by others; and when Dr. Randolph's body was brought to shore, his life was found to be extinct. It is believed that the shock and strain had led to immediate death from heart failure.

The value of an active mind in the world is inestimable. Its worth is but partly appreciated when the relationships which bound it to others are suddenly severed. There exist a favored few whose evolution is so perfectly co-ordinated that the intellectual life moves on with all the beauty of the seasons and the stars. To such the environment of circumstances is not a boundary, a limitation, but the line which marks the blending of personality into the lives of others through the sympathy occasioned by contact. Such men are not self contained, but possessing self they have the interest and sympathy of others, the better part. To such, the law of being is the thread of harmony on which their natures find a varied growth; true to this law they can be false to none. Such was he of whom we write, whose day of life was one long morning, whose task was so well done before the noon that the reward of finished labor and felicity was his.

E. P. D.

NATHAN LEWIS HATFIELD. M. D.

Nathan Lewis Hatfield, M. D., said to have been the oldest living graduate of Jefferson Medical College, died of old age at his residence August 29, 1887. He was born in Montgomery county on August 2, 1804, and began his education in the public schools of Trappe, then taught by F. R. Shunk, afterwards Governor of the State, and subsequently studied in the classical department of the University of Pennsylvania. He took two courses of lectures in the medical department of the same college and one at Jefferson College, being a member of the first graduating class—that of 1826—of the latter institution. He was engaged in the practice of his profession in this city for many years, though, owing to his advanced age, he had been leading a retired life for a number of years past.

At one time he was President of the Board of Health. He was a fellow of the College of Physicians; a member of the Philadelphia County Medical Society; of the North-

ern Medical Society of Philadelphia, of which he was once President; of the State Medical Society of Pennsylvania, of which he was Vice-President in 1865; of the American Medical Association; of the Jefferson College Alumni Association, of which he was President in 1874, and an honorary member of the California State Medical Association. He was also a member of the Rocky Mountains Medical Association.

Dr. Hatfield was twice married and was the father of five children.

JOHN R. HANEY, M. D.

John R. Haney, M. D., a well-known physician of South Camden, died at his residence on August 27, after a lingering illness, of Bright's disease. The deceased was born in Riegelsville, Pa., and commenced the study of medicine at an early age with Dr. Rosenberger, of Fredericktown, N. J. He graduated from the University of Pennsylvania in 1861. He served as a surgeon in the late war, and at its close practiced medicine at Erwinna, Pa. He located in Camden in 1867, and followed his profession in addition to conducting a drug store.

He was President of the Camden County Medical Society in 1883, and was also a member of the State Medical Society, the American Medical Association and the Camden City Medical Society.

Changes in the Medical Corps of the Navy for the week ending Sept. 3, 1887.

Med. Dir., Richard C. Dean, detached from duty as member of Examining and Retiring Boards and to Hosp., Chelsea, Mass.

Med. Dir., George Peck, orders as Delegate to International Medical Congress revoked.

Surgeon, M. H. Simons, detached from "Constellation" and to the Naval Academy.

Surgeon, B. F. Rogers, detached from Mar. Rendezvous, New York, and to the "Alliance."

Asst. Surgeon, James G. Field, detached from the "Vermont" and Mar. Rendezvous, N. Y.

Asst. Surgeon, C. P. Henry, ordered to the "Ossipee."

Pd. Asst. Surgeon, G. P. Iamsden, to the "Boston."

Asst. Surgeon, Louis W. Atlee, restored to duty.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from August 28, 1887, to September 3, 1887:

Lt. Col., Joseph R. Smith, Surgeon, ordered to report in person to the Surgeon General of the Army, on Sept. 2, 1887, on business connected with the public service, and on completion thereof to return to his proper station. Par. 9, S. O., 198, A. G. O., Aug. 26, 1887.

No. 1594. PHILADELPHIA, SEPTEMBER 17, 1887. VOL. LVII.—No. 12.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

SEVEN CASES OF GANGRENOUS STOMATITIS.

BY H. R. WHARTON, M. D.

Surgeon to the Children's Hospital, Instructor in
Clinical Surgery, University of Penna., Assistant
Surgeon to the Hospital of the University
of Pennsylvania.

During the month of July of this year there were brought to the Children's Hospital of Philadelphia from an Orphanage in this city, seven cases of gangrenous stomatitis. The disease had developed in these cases, after an epidemic of measles, which had existed in the institution from which they came, and they all presented the well-marked symptoms of this affection, gangrene of the mucous membrane and gums, with loosening of the teeth, and necrosis of the periosteum and jaws, to a greater or less extent, and, in several of the most severe cases, gangrene involving the thickness of the cheeks. These cases at the same time presented the marked constitutional symptoms of the disease.

Case I.—Mary McC., aged $4\frac{1}{2}$ years, was admitted to the Children's Hospital, July 5th, 1887. This patient was attacked with measles on June 4th, and apparently made a good recovery, but about July 1st it was noticed that a dark ulcerated spot had appeared over the second right incisor tooth, and this spot increased rapidly in size.

When examined at the hospital, the mucous membrane and gum of the alveolar portion of the right upper jaw were found to be in

a gangrenous condition, the alveolus was blackened and necrosed, the teeth were black and quite loosely held in their sockets, and the gangrene had to some extent involved the mucous membrane of the cheek upon the corresponding side.

The child was much emaciated, and had a very offensive discharge from the mouth, and a temperature which varied from 103° to 104° .

The patient was etherized and the loosened teeth were removed, the sloughing tissue was scraped away, and the whole of the gangrenous surfaces were swabbed with fuming nitric acid.

The patient was then ordered a mouth-wash composed of chlorate of potassium, tincture of myrrh, glycerine and water, which the nurse was directed to apply at frequent intervals. The patient was also put upon quinine and iron, and stimulants.

Upon the following day it was observed that the gangrenous process had attacked the lower jaw upon the same side, and had involved the soft parts adjacent. The loose teeth were removed, and the parts were thoroughly cauterized with nitric acid.

At this time the patient was conscious and took nourishment well, but suffered from pneumonia of the right lung, and had a very profuse diarrhœa, the temperature being 104° .

Upon the third day after its admission to the hospital, the child developed perforating gangrene of the cheek, and from the exposed alveolar sockets of the lower jaw, had a very profuse hemorrhage, which was only controlled by packing with dry lint.

The patient, after the hemorrhage, was in a state of collapse from which it only partly re-acted, and died some eight hours subsequently.

Case II.—Annie L., aged 2½ years, was admitted to the Children's Hospital on July 4th, 1887, having suffered from measles on June 12th. It was observed in this case that after the rash had disappeared the fever continued for some time; and that there appeared about July 1st a soft reddish spot over the second right incisor.

Upon examination, after admission to the hospital, it was found that a considerable portion of the alveolus of the right upper jaw was black and necrosed, the gum near the necrosed alveolus was gangrenous, and the adjacent mucous membrane of the cheek was also involved to some extent. The gangrenous tissues were scraped away, and the surfaces touched with nitric acid. The patient was put upon the same treatment as in the previous case.

This patient had a temperature of 101.3°, and suffered from a profuse diarrhœa, but took its nourishment well, and continued to improve for ten days, when the temperature again became elevated, and it was noticed that gangrene had again appeared at its former situation.

The same local treatment was again adopted, namely, the use of nitric acid, and after this time the patient made a good recovery. After the removal of the necrosed alveolus, which had become loose, she was discharged from the hospital in good condition.

Case III.—James S., aged 4½ years, was admitted to the Children's Hospital, July 8, 1887, having been attacked with measles, June 14th. On June 20th, there were noticed ulcerated spots upon the mucous membrane of the gum of the left upper jaw, and of the right lower jaw. Examination at the time of his admission showed extensive necrosis of the alveolus of the left upper jaw, and a greyish sloughing condition of the gums and mucous membrane of the left cheek; the alveolus of the right lower jaw and the soft parts adjacent thereto were also involved.

The loose teeth were removed and the parts thoroughly touched with nitric acid, and the same local and constitutional treatment was applied as in the other cases. This patient also suffered from a profuse diarrhœa, and had a temperature ranging from 102° to 104°.

In spite of treatment this patient became rapidly worse, the discoloration of the cheeks extending, and spots of gangrene appearing

over the left cheek and lower portion of the right cheek; the patient died of exhaustion on July 11th.

A post-mortem examination was made in this case by my colleague, Dr. G. E. de Schweinitz, who has furnished the following notes:

Autopsy six hours after death: body of an emaciated male child; spots of gangrene in the left cheek, over the body of the inferior maxilla, and over the mastoid process of the right side; very slight post-mortem rigidity and posterior ecchymoses.

Thorax: The entire contents of the thorax appeared perfectly natural.

Abdomen: Position of viscera about normal; no fluid. *Liver:* Enlarged, its tissue firm and congested; some recent adhesions between its under surface and the hepatic flexure of the colon. The gall bladder distended with bile of a pale-yellow color; the ducts pervious. *Spleen:* Normal in size and consistence. *Kidneys and supra-renal capsules:* These showed no gross changes; some few adhesions existed between the anterior surfaces of the kidneys and the ascending and descending colon respectively; these adhesions were most marked upon the right side. *Stomach and intestines:* In the stomach and small intestines no gross lesions were discovered. The mucous membrane of the head of the colon and appendix was thickened and congested, but not ulcerated. The mucosa of the ascending and transverse colon was spotted over with round oval patches of grayish false membrane, separated from each other by areas of swollen and congested mucous membrane. This condition became more marked as the descending colon was reached, and just above the sigmoid flexure these deposits became confluent, so that the entire inner surface of the gut was completely covered over with a dense, gray-white, granular false membrane. This state of affairs continued to the end of the rectum. The walls of the large intestine were everywhere thickened and in the region just described measured 1.5 cm. in thickness.

The mesenteric and retroperitoneal glands were enlarged and soft. The rest of the abdominal organs were normal. The brain and spinal cord were not examined. *Microscopical examination* of the large intestine showed very well the lesions of *diphtheritic dysentery*. The necrosis of the mucous membrane was in places superficial, but in the lower portions of the gut the entire mucosa had been substituted by a granular mass in which structural elements were no longer recognizable. The sub-mucosa was infiltrated

with small cells. No such infiltration existed in the muscular layers, and hence the thickening of the walls depended upon this deposit of false membrane and the swelling and infiltration of the sub-mucosa.

Case IV.—James F., aged 4 years, was admitted to the Children's Hospital, July 9th, 1887, having suffered from measles during the month of June. Examination of the patient at the time of his admission to the hospital showed that the alveolus of the upper jaw corresponding to the four incisors was blackened and necrosed; the hard palate was also extensively necrosed and exposed, while the gum and mucous membrane of the upper lip and a portion of the soft palate were in a gangrenous condition. The same local and constitutional treatment was instituted in this case as in the others.

This patient suffered from diarrhœa, which at times was profuse, and had a temperature of 102° , but gradually improved until the tenth day, when his temperature suddenly became elevated, and examination showed that the gangrene had again begun to spread and that a portion of the lower jaw and gum were also involved.

The affected parts were again cauterized with nitric acid, and after this time his improvement was continuous, and at the time of this report he is in good condition although the necrosed bone has not yet separated.

The following cases were not admitted to the hospital, but were treated in the surgical out-patient department by the surgeon on duty. Dr. Edward Martin:

Case V.—John S., aged 4 years, was brought to the out-patient department of the hospital, July 5th, 1887, having had measles during the month of June. He suffered from necrosis of the alveolus and gangrene of the gum of the upper jaw about the location of the right upper canine tooth. The gangrenous tissue was scraped away and the surface was touched with nitric acid, the loose teeth being removed. The same local and constitutional treatment was instituted as in the previously reported cases and the patient made a good recovery.

Case VI.—Katie R., aged $5\frac{1}{2}$ years, was brought to the out-patient department of the hospital, July 5th 1887, having suffered from measles in June. This patient presented a patch of gangrenous tissue and necrosed alveolus corresponding to the position of the lower left canine tooth. The loose teeth were removed and the same treatment was applied as in the other cases; and the patient made a good recovery.

Case VII.—Mamie C., aged 4 years, was brought to the out-patient department of the hospital, July 5th, 1887, having suffered from measles during the month of June. She presented necrosis of the alveolus and gangrene upon the left side of the lower jaw. The same treatment was instituted, and the patient made a good recovery.

REMARKS.—Gangrenous stomatitis is comparatively a rare disease and is only seen among the ill nourished children of the very poor classes, or in homes or asylums for children where the inmates are often overcrowded and poorly fed, and where there are naturally many cases whose constitutional condition predisposes them to poor nutrition.

The disease is usually developed in such subjects after some acute disease, such as measles, scarlet or typhoid fever, and is also said to have been observed after pneumonia, bronchitis and dysentery. As sequelæ of the latter diseases I have never seen the affection, and in the cases which have come under my personal observation I have generally been able to trace its origin to an attack of measles. I think all authorities are agreed that measles is the disease upon which this affection, in suitable cases, is most apt to follow, and in this country it is certainly very unusual to see gangrenous stomatitis develop after the exhausting intestinal diseases of children which are so common during the summer months.

There has recently been described a special form of micrococcus which is supposed to be directly concerned in the production of gangrenous stomatitis, and further investigation may establish its pathological significance.

It is still a mooted point whether or not the administration of mercury in the treatment of the acute diseases of children has any causative relation to the development of gangrenous stomatitis. In the previously reported cases I have ascertained that this drug was not administered, and indeed I am inclined to agree with Mr. Heath, who thinks that the extensive necrosis of the jaws and destruction of the soft parts of the mouths of children, which were formerly so generally attributed to the administration of this drug, were really sequelæ of the exanthemata.

The disease generally first appears as a spot of ulceration upon the mucous membrane of the gums and rapidly extends to the jaw and cheek.

Gangrenous stomatitis, when well developed, cannot well be confounded with any other disease, and it is only in the very

early stage of this affection that it is possible to confuse it with the much less grave affection, ulcerative stomatitis.

If one examines carefully the mouth of a patient suffering from gangrenous stomatitis, he will see upon the gums or upon the mucous membrane of the swollen cheek an ulcerated surface covered with a brownish or greenish or dirty gray colored slough surrounded by cedematous mucous membrane. If the disease is well advanced, the bone of the jaw and soft palate may be seen blackened and dead, and the discolored teeth are found to be loosely held in their sockets and may be shed or can be easily drawn. There is also a profuse discharge of fetid saliva, and the sub-maxillary lymphatic glands are generally enlarged.

In severe cases the gangrenous process extends rapidly to the cheek where a black slough appears, and this may drop out leaving the cavity of the mouth exposed, causing the patient to present a most horrible deformity.

The seat of perforation of the cheek is generally continuous with the most extensive seat of disease in the jaw; the cheek corresponding to either the upper or the lower jaw may be involved. I remember a case which was under my care at the Children's Hospital a few years ago, in which a portion of the lower lip and chin was destroyed by a slough; in this patient recovery took place and the deformity was very well relieved by a plastic operation. If patients survive after extensive destruction of the cheek it is often impossible to obtain sufficient flaps to cover the gap in the cheek, and there is often so much cicatricial contraction that the motion of the lower jaw is impaired or it may be completely locked; in either of these events the patient presents a most miserable condition.

During the time that these local conditions exist in the mouth the patient has a more or less elevated temperature, but generally rests well and rarely refuses nourishment; it is often remarkable to see these patients continue to take nourishment with apparent relish almost up to the time of the fatal termination.

The principal complications occurring in the course of the disease are diarrhoea, broncho-pneumonia and hemorrhage. The former of the-e is I think one of the most constant complications and is probably due to the ingestion of gangrenous or septic matter with the food, and the exhaustion following it is a very frequent cause of death. In Case III, in which a post-mortem examination was made, the causation of the diarrhoea is ex-

plained by the condition of the mucous membrane of the large intestine.

Broncho-pneumonia is another complication of comparative frequency and is probably produced by the aspiration of gangrenous fluids and gases into the air passage.

Hemorrhage occurring at the time of the separation of the sloughs, may be a serious complication, and in Case I. the exhaustion following this accident was an important factor in the fatal issue.

In the treatment of this disease, it is most important that the patient be given a nutritious and early assimilated diet together with stimulants; and at the same time the administration of quinine and iron with the mineral acids is often followed by the best results. The administration of opium has been recommended in this affection by reason of the influence it seems to exert in controlling the spread of gangrenous diseases; but with its use in this disease I have had no personal experience. The local treatment which I have found most satisfactory is the removal of the gangrenous tissue as far as possible by scraping, and the thorough application of nitric acid to the affected parts. The application of the actual cautery to the diseased surfaces (and the most convenient form for its use is by means of Pacquelin's cautery,) has also been highly recommended and it has the advantage over the use of nitric acid, that its action is more readily controlled.

The mouth should be kept constantly washed with some form of disinfectant solution, and I have used with advantage a solution of chlorate of potassium with glycerine and tr. myrrh, or an infusion of sumac with chlorate of potassium.

In cases which terminate favorably, the sloughs separate and the ulcerated surfaces are covered with healthy granulations; the necrosed bone becomes loose, and is either thrown off or can be easily removed; and with the improvement in the local condition there is a corresponding change in the patient's constitutional state.

—“It is my painful duty, madam,” he said, “to inform you that lightning has just struck your husband.”

“Did it strike him more than once?” she asked anxiously.

“No, ma'am.”

“Thank Heaven it's no worse!” she said, with a sigh of relief; “If lightning only struck John once, he'll pull through.”—*Puck*.

CHOLERA IN SOUTH AMERICA.

LIEUT. A. B. WYCKOFF, U. S. N.,
U. S. Flagship "Lancaster."

A study of the development of cholera, during the past summer in the Argentine Republic, Uruguay and Chili, should convey some useful lessons to the people of the United States. Not being a physician, I cannot speak with any authority regarding the causes of its appearance in the various localities; nor as to the efficiency of the measures used in its treatment. I have found it exceedingly difficult to get correct information as to the dates of its first appearance, the number of cases, and number of deaths, in the different towns. But the approximate data, which I give, convey an adequate idea of the severity of the epidemic, and the remarkable rapidity with which the disease traveled.

Cholera was undoubtedly brought to the Rio de la Plata by the Italian emigrant steamer "Perseo." This vessel anchored off Buenos Ayres on October 12th, 1886; and rumors of the existence of cholera on board had been telegraphed from Montevideo two days previously. One of the leading daily papers of Buenos Ayres contains the following in its issue of October 13th, 1886: "The 'caso sospechoso' steamer Perseo is in the roads in quarantine. All the alarm about her is moonshine. The deaths on board were of babies a few months old, and of an old fellow of 70, who is, we hope, better off in the next world."

This ill-fated steamer was intended to carry about 1000 passengers, whereas 2017 had been packed on board on this trip. Unfortunately for all the populous towns and fair villages, afterwards devastated by the dread disease, the "Perseo" arrived at Buenos Ayres just at the time when the inaugural festivities of the new President of the Republic, Dr. Celman, were taking place. And a still greater misfortune than the crowded condition of her steerages was the presence in the cabin of the "Perseo," of a prominent Argentine politician, who had been to Italy upon some diplomatic mission. This gentleman could not conceive that 22 deaths from cholera in the steerage during the passage was any reason why he should be deprived of the pleasure of being present at the inaugural ceremonies. It seems as necessary for politicians to keep an eye to windward, with regard to future advantages, in the Argentine Republic, as in the United States. The gentleman's political friends pulled the

proper wires, and the great man was relieved from quarantine, and allowed to land and dance at the inaugural ball. Immediately, the other cabin passengers, with great reason, urged that they had been no more exposed to the cholera than the politician, and should, therefore, also be allowed to go on shore. Their request was no sooner granted than the passengers in the second cabin advanced the same arguments. The final result was, that at the end of three days, a large number of the passengers from the "Perseo" were wandering through the streets of Buenos Ayres. On October 15th, the paper previously quoted, remarked: "There is considerable uneasiness in the public mind about the 'Perseo's' passengers being allowed to land after three days' quarantine."

On October 20th, two sailors died on board a Government vessel anchored in the Riachuelo, and while it was quite certain that these were cases of cholera, the attempt was made to attribute their deaths to other causes. The Riachuelo is an anchorage, which has been made by dredging the mouth of the river of that name. The part of the city, extending along this water front, is termed the "Boca;" and is a low, swampy place, without drainage and with numerous pools of stagnant water. The filthy residents of the Boca are principally Italian and Spanish sailors' families, and the usual human birds of prey who live at the expense of ignorant sea-faring people. They are crowded together in miserable huts, without ventilation; and their drinking water is full of putrescent animal and vegetable matter. The water of the Riachuelo is, in fact, so bad that it kills all the fish that enter this river which, does not, however, prevent the poorer classes from using them as food.

A large number of the steerage passengers of the "Perseo" naturally drifted at once to the Boca; and there is little doubt but that suspicious cases began to appear there immediately afterwards. The facts were suppressed, however, until about November 3d, when several cases daily began to be reported. The attending physicians still insisted that it was not Asiatic cholera, but only "colera nostra" or English cholera.

On November 6th, twelve suspicious cases were reported at Rosario, a city of 50,000 inhabitants some 200 miles up the Parana river. As there are numerous steamers plying constantly between Buenos Ayres and Rosario, it is probable that many of the "Perseo's" passengers were carried to that place. On November 7th, ten deaths occurred at Rosario, and a number of fatal cases in the

Boca at Buenos Ayres. The city authorities now began to awake to a realizing sense of the danger; and a large force of men was employed to cleanse the Boca and other offensive districts. All of the vessels were ordered from the Riachuelo to the outer anchorage, some miles distant. When a case of cholera was reported, the house was at once isolated, and no one but the physicians either allowed to enter or depart. Disinfectants were lavishly used, and finally many of the huts in the Boca, with their contents, were burned. During the remainder of the month of November, there was a daily average of 7 or 8 deaths. The wealthier inhabitants fled in all directions, and, as a consequence, the epidemic was soon reported at distant points, and invariably on the direct line of travel.

By December 10th, twelve or fifteen cases daily were reported at Cordoba, a city of 40,000 inhabitants on the Central Argentine R. R., 246 miles from Rosario and 430 miles from Buenos Ayres. The same day it made its appearance at Mendoza, on the Andine R. R., some 650 miles west of Buenos Ayres. By December 13th, it had traveled southward along the Great Southern R. R., 450 miles to Bahia Blanca, and northward along the Great Northern R. R., 800 miles to Tucuman.

When the cholera was first reported at Buenos Ayres, the Republic of Uruguay shut off all intercourse with the Argentine, and established a military cordon along the frontier, while numerous boats were kept patrolling on the river. No persons, merchandise or even letters were permitted to enter. But notwithstanding the most vigilant precautions, by means of small boats on dark nights, some individuals from Buenos Ayres undoubtedly managed to reach Montevideo. On December 5th, the authorities of the city gathered up all the vagrants about the streets, and placed them in the poor-house at La Union, four miles distant. On December 8th, six cases of cholera were reported at this institution, and the disease gradually spread throughout the city in defiance of the most rigid precautionary measures. As Montevideo has an excellent situation, and is well paved and drained, with a healthful water supply brought from a distance of some thirty miles, the energetic government managed to curtail the ravages of the disease. In a population of over 100,000, there were not more than seven hundred deaths, and the disease disappeared by March 1st, 1887.

Thus we find, that in about one month after cholera was acknowledged to exist at

Buenos Ayres, and in less than two months after the arrival of the emigrant steamer "Perseo," the epidemic had spread along the existing lines of travel to the limits of the Argentine Republic, viz.: 450 miles to the southward; 800 miles to the northward; 650 to the westward, and had reached Montevideo, 100 miles to the eastward.

During the month of December, the cholera was raging in almost every town in the Argentine. The freaks of the epidemic were apparently very strange. A low-lying city of 400,000 inhabitants, like Buenos Ayres, with exceedingly unhealthy wards, where the population was crowded together in miserable hovels, and no sanitary laws were observed, should have been a congenial locality for the disease. But there had been only five hundred deaths from cholera in this city up to January 1st, 1887; while in Rosario, with one-eighth the number of inhabitants, over one thousand fatal cases had occurred. Tucuman, with its 30,000 people, has an admirable situation on a table land, near the Sierra Aconquija, in the northern part of the Republic. Yet within about two weeks after the first appearance of the disease there, over two hundred people died in a single day. This terrible result may be partly charged to inefficient measures of treatment, and to the ignorance and bigotry of the people. When the health authorities made an attempt to destroy the fruit in the place, they were attacked by a mob and four of them killed. The ignorant "gauchos" even believed that the physicians would poison any one taken sick with choleraic symptoms. It is related that one virago, from sheer bravado, in the presence of the doctors, broke open and ate a watermelon and drank copiously of the water against which they were being warned. In four hours she was a corpse.

At Mendoza even more frightful scenes were enacted. This city has about 25,000 inhabitants; is delightfully situated at the foot of the Andes, some twenty-five hundred feet above sea-level, and is reputed to have the healthiest and most enjoyable climate in the world. In 1861 the town was entirely destroyed by an earthquake, when 13,000 people perished. The new Mendoza is built quite near the site of its ill-fated predecessor. It is regularly planned, with wide well-paved streets, and numerous shade trees. The city is kept very clean, and the houses are substantial and well built, while even the peasantry reside in neat, vine-clad cottages. The people are comfortably clad, and healthful food is cheap and abundant. A canal drawn from the river Mendoza traverses the city

and irrigates the vineyards and gardens. The average death-rate in this model city has been only 15 per 1000. Yet, within a week after the appearance of the dread disease, the people were dying at the rate of fifty per day. Its existence was first reported December 13th, and on Christmas day there were over one hundred deaths. The inhabitants were panic stricken, and fled in all directions. It was estimated that more than one-half the houses were vacated. The dead were left unburied and the sick unattended, until, at last, the convicts in the prisons were given their liberty for assisting in throwing in and covering the bodies in a huge ditch constructed for the purpose. The dead were found everywhere scattered over the hills and plains, wherever the dread disease had attacked them. During the height of the epidemic, almost every case was fatal. This same result was noticed in many of the smaller towns, where the medical assistance was insufficient. Locomotives were finally sent to Mendoza, and all the water used was boiled. This seemed to have a good effect in checking the ravages of the disease, as was also found the case at Tucuman.

During the month of December the temperature at Buenos Ayres ranged above 90° Fahrenheit on many days.

When cholera was first reported at Buenos Ayers, the Government of Chili adopted a rigid non-intercourse policy against the Argentine and Uruguay. A military blockade was established at all the passes of the Andes, and steamers that had touched at Montevideo or Buenos Ayres were not even allowed to communicate with the shore upon arrival at Valparaiso.

The cholera was at its worst stage in Mendoza during the last week of 1886. This city is situated near the entrance of the two passes in the Andes generally used in the intercourse between the Argentine Republic and Chili. By the Uspalatta Pass it is two hundred and fifteen miles from Mendoza to Santa Rosa, the end of the railroad in Chili. It usually requires six days' travel on mule-back to accomplish this journey. By the more difficult Portillo pass it is less than two hundred miles from Mendoza to Maypu.

Christmas Day the epidemic culminated in Mendoza, and the following day there were four cases and one death at San Felipe, over two hundred and fifty miles distant in Chili; and December 27th, there were twelve cases and eight deaths. On these same days a heavy rain storm had passed over Mendoza and the Uspallata Pass, and spread over the province of Aconcagua, in which

San Felipe is situated. The cholera rapidly spread throughout this province, and on January 12th, seventy-seven deaths were reported.

At the first appearance of cholera in the province of Aconcagua, a close military cordon was formed around Santiago, the capital city of Chili, and all ingress was practically stopped. Santiago has about 175,000 inhabitants, and a better site for a city could hardly have been chosen. It is situated at a considerable elevation above the sea, in the centre of a plain surrounded by hills. The air is pure and dry, and a large mountain stream flows through the city. The streets are broad, well paved, and are kept very clean. The wealthier inhabitants of Chili have congregated there; and have magnificent houses and grounds and live regardless of expense. Notwithstanding all these conditions apparently unfavorable to it, the cholera appeared in the suburbs on January 21st and soon spread throughout the city. It also appeared almost simultaneously in the small villages of the surrounding province. On February 18th, there were one hundred and eleven deaths in Santiago, and by April 1st, there had been about twenty-five hundred victims to the disease. Valparaiso also attempted, by a cordon, to prevent the entrance of cholera on the land side. But although this and other precautions may have delayed its march, it no less surely appeared about the middle of February.

By March 1st, 1887, the cholera had apparently run its course in the Argentine and Uruguyan Republics, and at the beginning of April no more cases were reported. A few cases daily still continued to occur in April, at Santiago and Valparaiso, Chili; but the disease has practically suspended operations, until the hot weather of next December may cause it to break out again with renewed activity.

The useful lessons, from the cause of this dreadful epidemic in South America, are readily gathered. Because of the neglect of proper quarantine regulations at Buenos Ayres, these countries have lost thousands of their inhabitants, and all business was completely paralyzed for several months. The development of the Argentine Republic has been delayed at least one year, and great fear exists as to the future; for their experience of epidemics has led them to believe that the second season is worse than the first.

After Asiatic cholera has once obtained a foot-hold in any populous country, it seems quite impossible to prevent its spreading. If any Italian emigrant ship should introduce it into New York, it would speedily appear at

Chicago and St. Louis. The cholera germs can be carried in a thousand unsuspected ways, and it is even probable that the atmosphere may be the medium of conveyance for considerable distances.

It is quite evident, then, that the National Government should institute a strict quarantine, if not positive non-intercourse against those countries where the disease is epidemic; for all the seaboard cities of the United States cannot be trusted to observe the rigid precautions which are absolutely necessary. Let a single city neglect its duty, and the inhabitants of the entire country will surely be the sufferers. And even if the quarantine laws of the United States prove effectual as to the coasts, there remains the positive danger from Canada and Mexico.

The precautions observed in the Argentine, Uruguay and Chili, to check the ravages of the disease after it had appeared, were very much the same as have been used in other countries, viz.: special hospitals, rigid isolation of houses where there have been cases, profusion of disinfectants, destruction of all articles that have been in contact with patients, boiling of all water used for drinking, abstention from all fruits, especially watermelons, and careful inspection of all other food.

THE EYE OF THE ADULT IMBECILE.

BY CHARLES A. OLIVER, M. D.,

Ophthalmic Surgeon to St. Mary's Hospital and to the Maternity Hospital, Philadelphia.¹

The following observations and conclusions are based upon the examination of the eyes of twenty young adult male imbeciles seen at the State Hospital for the Insane at Norristown, Pa., and are given as a contribution to the subject of the significance of the local conditions so generally found in adolescent and young adult eyes which are the victims of asthenopia, and are undergoing changes in refraction.

During the examination the following precautions were observed:

First. Care was taken to exclude all but the proper class of subjects.

Second. Subjects chosen whose eyes were free from extraneous disease or inflammation.

Third. Young adults were used.

Fourth. Males were taken.

Fifth. Every subject was submitted to the same routine examination.

Observations.

Subjective.

First. Direct vision for form, as a rule, normal.

Second. Accommodative action: impossible to obtain any reliable result.

Third. Visual fields: nothing could be gotten

Fourth. Color perception probably normal.

Objective.

Fifth. Pupils generally relatively equal in size, but frequently opposed to each other in their long diameters.

Sixth. Irides equally, though sometimes sluggishly mobile to light-stimulus, convergence and accommodation.

Seventh. Extra-ocular motion intact in all directions; slight insufficiency of the interni found in one-half of the cases.

Eighth. Optic disc seemingly healthy; more so than would be expected for age.

Ninth. Physiological excavation frequent; usually small, shallow, oval in outline, and occupying a position slightly to the temporal side of the centre of the disc.

Tenth. Scleral ring as a rule visible all around disc, and slightly broader to the outer side.

Eleventh. Pigment massings beyond scleral ring generally limited to narrow concentric splotchings and double loops, with undisturbed areas beyond and between.

Twelfth. Entire absence of the so-called absorbed *conus*.

Thirteenth. Fibre-layer of the retina but very slightly increased in thickness.

Fourteenth. Very few lymph reflexes and opacities of vascular sheaths.

Fifteenth. Retinal vessels about normal in comparative size, and in a few instances carrying impoverished blood.

Sixteenth. No change in the choroid, except a somewhat granular condition, more pronounced in macular region; this sometimes being accompanied by a slight absorption of epithelium (especially amongst the most intelligent).

Seventeenth. Almost equal degrees of H., with slight amount of As. present in every case.

Eighteenth. Absence of any congenital external or internal gross local malformation.

Nineteenth. The less imbecile the subject, the more common were the ordinary conditions seen in the used eyes of the mentally healthy.

¹ Abstract of a paper read before the American Ophthalmological Society, July 21st, 1887.

It must be remembered that these observations do not hold absolutely good as written in every individual case, each subject presenting different degrees of the main features expressed in seemingly due proportion to amount of intelligence and consequent use of eyes for continued near-work. They merely show what should be expected in an average case, and thus serve to express the type.

Conclusions.

First. The present study tends to show that the adult eye of the imbecile is an organ which is capable of proper functional activity, and that the want of action is in the main due to what may be termed intellectual hebetude.

Second. By reason of mental incapacity which has supervened in such subjects before the eye has been brought into continued and constant action as an instrument of accurate and delicate use, the ordinary appearances seen in the used eyes of the mentally healthy are lessened in due proportion to the amount of work given to the organ.

Third. The want of these physical changes, presenting a picture almost identical to the one seen during infantile existence, may be considered as typical of an unused, healthy, adult, human eye.

Fourth. The healthy eye of the adult imbecile, therefore, serves to teach us that the various conditions known as insufficiency of the interni, dirty red-gray appearance of the optic-disc, irregularity of physiological excavation, non-visibility of the superior and inferior portion of the scleral ring, absorbing conuses in all of their varieties, increase in density and thickness of the retinal fibres, opacities of vascular lymph-sheaths, disturbed states of the choroid, and gross errors in astigmatism with changes in indices of refraction, which are so frequent in the used eye of the mentally healthy, must be considered as pathological changes, expressive of low inflammatory action, with stretching and distortion from increased intraocular and extraocular pressure; these being representative not only of general want of tone so often seen amongst those of sedentary life, but of constant and frequent abuse of a delicate organ.

1507 Locust Street.

—A colored man who had been bitten by a rattlesnake claimed to have been cured by whiskey and an application of raw chicken-flesh. It is hard to tell which had the power to effect a cure; but the colored race and the chicken draw pretty well together.—*Puck.*

HELONIAS IN UTERINE HEMORRHAGE.

BY A. NOEL SMITH, M. D., OF DOVER, N. H.

In the evening of the 26th of February of the present year, Mr. H. called at my office to consult me in regard to the condition of his wife, and gave me the following history:

Three weeks previous she had miscarried, between three and four months, this, having been her fourth pregnancy, but first miscarriage. The foetus alone was said to have come away at that time—nothing like a placenta, and very little hemorrhage. Indeed, the next evening she attended a concert, and for several days moved about quite a little, both walking and riding. Soon, however, hemorrhage came on, at times being quite profuse. And up to the date of the husband's coming to me there had been nothing which they were at all sure was placental in appearance. Without seeing the patient, I prescribed ext. ergot fld. gr. xx. t. i. d., and enjoined quiet.

March 1st, no better; made a visit; constant flow from uterus, but quantity not large; os very slightly dilated; no presentation of membranes; there being no rise in temperature, no chill, and no symptoms of septic poisoning, thought it not advisable to open up uterus.

Gave the following, continuing ergot:

R Acidi gallici..... $\overline{5}$ j
Syr. simp..... $\overline{f}$ $\overline{3}$ j
M. deinde adde
Aque cinnamom..... $\overline{f}$ $\overline{3}$ iv
Aque pure..... $\overline{f}$ $\overline{3}$ iij
M. S.—Tablespoonful every four hours.

Ordered, also, vaginal injections of hot water, nightly; after this, until April 11th, some little improvement, but still constant drain.

May 2d, patient discouraged, and nearly as bad as ever, yet not confined to bed. All former treatment was suspended, and she was given pil. quin. sulph. (gr. ij), one three times daily. As the result of this there was very slight improvement for four days, but not a day passed without considerable hemorrhage.

May 22d, prescribed Mist. Helonin Co. (Schlotterbeck), one teaspoonful four times daily. This mixture is composed of the resinoids, helonin, senecin and avenin. My patient had been taking this preparation four days, when I was summoned to the house to attend another member of the family; and I was both surprised and glad to be informed

that with the administration of the helonias there had been a marked improvement, until now, there was no flow whatever. Continued the same remedy daily, and, June 19th, the patient menstruated regularly for the first time since before impregnation. Flow continued five or six days, ceased, and at this writing there has been no recurrence of hemorrhage.

Now, although there was no *positive* evidence of placenta coming away in this case, yet I am inclined to the opinion that the uterus was emptied before I saw the patient, there remaining an intractable case of menorrhagia to deal with. The hemorrhage ceasing as it did does not seem to me a mere coincidence, as the agents usually depended upon to control it were faithfully tried, with little or no effect. Then the helonias mixture came to the rescue, the result being only what has from time to time been claimed for it.

SOCIETY REPORTS.

NINTH INTERNATIONAL MEDICAL CONGRESS, WASHINGTON, 1887.

TUESDAY, SEPTEMBER 6TH (*continued*).

Section on Anatomy.

Dr. L. H. Dunning read a paper at the morning session upon "The Anatomy and Surgical Importance of the Peri-renal Cellulo-adipose Tissue and Renal Capsule." He found this to lie in the fact that these tissues are subject to inflammation and morbid changes. He thought all loose portions of fat should be removed, and, in general, every tissue that is too vascular.

Dr. Oppenheimer, of Richmond, Va., read a paper upon "An Apparatus for the Treatment of Fractures of the Surgical and Anatomical Neck of the Humerus." This apparatus was a sort of iron cage which was to be fastened around the chest with plaster of Paris.

At the afternoon session, the address of the President, Dr. Wm. H. Pancoast, was delivered. He spoke of the great advances which had been made in microscopical anatomy, and then referred to the anatomy of the joints. He also mentioned some anomalies of muscles that he had observed, and declared his opinion that deep fasciæ were ligaments as well as protectives.

Dr. Albert B. Strong, of Chicago, Ill., then read a paper upon "Frozen Sections of the Male Pelvis, and the Anatomical Relationship of the Pelvic Organs with Especial Reference to Supra-public Cystotomy."

Following this paper was one by Dr. F. C. Schaefer, also from Chicago. His paper was upon "Anatomical Points Involved in the Complete Loss of Scalp, Including One Ear and the Greater Portion of the Eyelids." This paper was descriptive of a case in which a girl had been caught by the hair in a factory, and had her scalp torn off. Skin grafting gave him the best results in the way of cure, which he illustrated by photographs. Small grafts seemed better than large, and should be placed close together.

Section on Dental and Oral Surgery.

Dr. Wm. Carr, of New York city, gave a clinical demonstration of the treatment of fractures of the maxillæ with a modified interdental splint. He recommended that an impression in wax be taken, after bringing the parts into as close apposition as possible, and removing loose teeth and splinters of bone. From the wax model, an interdental splint should be made of hard rubber. A space is left in the splint in front of the incisors of the upper jaw through which to give nourishment. The mouth should be disinfected; for this purpose, the author prefers a three per cent. solution of peroxide of hydrogen, or a solution of bisulphate of soda, in the proportion of one drachm to the ounce. The splint, in ordinary cases, should be kept on from three to four weeks.

Dr. E. Brasseur, of Paris, France, then read a paper upon "The Use of Air in Dental Therapeutics," in which he recommended hot air as a germicide.

At the afternoon session, Dr. Junius E. Cravens, of Indianapolis, Ind., read a paper entitled, "The Management of Pulpless Teeth."

After stating that pulpless teeth were not dead, he entered his protest against the use of escharotics, and urged that the pulp-canal should be thoroughly cleaned, and then hermetically sealed with tin-foil.

The paper was discussed by Dr. Thos. Fillebrown, of Maine; Dr. A. W. Harlan, of Chicago, Ill., and Dr. W. C. Barrett, of Buffalo, N. Y., all of whom differed more or less emphatically from the author of the paper.

The next paper was by Dr. T. E. Weeks, of Minneapolis, Minn., upon "Matrices as

Adjuncts in Filling Teeth." He urged simplicity in construction, cheapness and adaptability as the points to be aimed at.

Section on Climatology and Demography.

The address of the President of the section was given in our last issue.

The second paper was by Dr. Charles Denison, of Denver, Colorado, upon "The Preferable Climate for Phthisis." The author recommended a climate found in the United States at an altitude of from fifteen hundred feet in the North in winter, to ten thousand feet in the South in summer. Contra-indications to such a climate are an excitable nervous temperament; valvular lesions, with rapid action of the heart; marked and extensive emphysema; pneumothorax and hydro-pneumothorax; active pneumonia or hæmoptysis; high bodily temperature; extensive involvement of lung-tissue, and similar conditions.

Dr. Jno. Wm. Moore, of Dublin, Ireland, read the next paper on "The Seasonal Prevalence of Pneumonia." The author argued for the belief that pneumonia is an infectious disease, basing his conviction upon its occasional epidemic prevalence, and upon the character of the symptoms, their mode of onset, etc.

Dr. Henry B. Baker, of Lansing, Mich., also read a paper, entitled "The Relations of Certain Meteorological Conditions to Acute Diseases of the Lungs and Air-passages." The author stated that cold air is always dry air, and that diseases of the air passages are caused by this cold dry air abstracting moisture from the tissues over which it passes.

Section on Therapeutics.

Dr. Hugh Hamilton, of Harrisburg, read a paper upon "The Chemical Philosophy of Remedy." He quoted Jaksch as saying that "remedy may be defined as the use of means to restore the body to healthy condition by prophylaxis"—repair of injury and the correction of nutrition. He argued for the employment of antiseptics in modified form in internal medication.

Dr. Ralph Stockman, of Edinburgh, stated that a ptomaine was obtainable from phthisical sputum which was capable, when injected into mammals, of producing progressive emaciation; but that opium and belladonna, administered after this alkaloid had been injected, had power to stay the disease, so that the animal recovered.

The next paper was by Dr. J. S. Sinclair Coghill, of Ventnor, Isle of Wight, England.

Its title was "Chlorate of Potash." The speaker claimed that this salt liberated its oxygen to the blood. He also claimed for it tonic and stimulating powers.

Dr. D. F. Phillips, of London, England, then read a paper upon "The Action of Certain Drugs on the Circulation and Secretion of the Kidney." As the result of his experiments, he concluded that the flow of urine was determined not so much by blood-pressure as by the rate of flow of the blood through the renal vessels.

The next paper by S. S. Wallian, of New York, on "The Neglect of Non-Medicinal Therapeutics," was a plea for the abandonment of drugs in favor of baths, massage, electricity and hygiene.

Section on Diseases of Children.

Dr. Moncarvo's paper on "Hereditary Syphilis and Rickets in Brazil," was read. The former furnished sixty per cent. of the cases of infantile disease. Rickets was present in forty-five per cent. of the cases that came under his observation. More than two-thirds of the rickety children show signs of syphilis. He therefore regards hereditary syphilis as an important factor in the production of syphilis.

The next paper was by Dr. Wm. Stephenson, of Aberdeen, Scotland, on the "Rate of Growth of Children." The maximum growth occurs in girls from the eleventh to the thirteenth year, and in boys from the fourteenth to the sixteenth year. He attributes the fact that puberty is a critical and trying time not to the development of the reproductive organs, but to the great activity of growth which then occurs.

Dr. Victor C. Vaughan read a paper on "The Use of Cow's Milk in the Artificial Feeding of Infants." The writer was opposed to the practice of giving milk during cholera infantum. In the discussion that followed the reading of this paper, all of the speakers were alive to the danger that might result from the use of milk, but most of them were accustomed to rely upon some preparation of the milk to render it innocuous.

At the afternoon session, the first paper read was by Dr. Wm. P. Northrup, of New York, upon "The Pathological Anatomy of Laryngeal Diphtheria as Related to Intubation."

In autopsies of children who had died after having worn the O'Dwyer tube from three to seven days, there was found only an abrasion of the superficial epithelium, until the occurrence of an epidemic of measles, in which many deaths occurred from complications. He found the cause of death had been mostly

extension of pseudo-membrane to the bronchi, and pneumonia.

Three papers followed upon Intubation of the Larynx. The first was by Dr. E. Bouchut, Paris, France; the second by Dr. Joseph O'Dwyer, of New York; the third by Dr. F. E. Waxham, of Chicago, Ill.

Dr. O'Dwyer concluded that intubation was only a simple operation in an easy case, and when done with dexterity and coolness. Intubation, even when perfected, can never be considered a satisfactory remedy, in view of the complications and nature of membranous croup.

Dr. Waxham was a strong advocate of intubation, but was not blind to its disadvantages; the operation is difficult of performance; the soft tissues may be wounded or the trachea perforated. It is more difficult to withdraw than to insert the tube. The author stated that the operation had been performed one thousand times in two years, and that two hundred and sixty-nine lives had been saved from certain death.

Dr. Jennings, in the discussion that followed, expressed his preference for tracheotomy.

Dr. Pitner questioned the correctness of saying, as Dr. Waxham did, that 249 recoveries meant 249 lives saved, as it is impossible always to tell whether a child will die or not.

Dr. Northrup declared that he had never experienced any difficulty in performing intubation. The only drawback to the operation lay in subsequent feeding of the patient.

In concluding the discussion, Dr. O'Dwyer expressed the opinion that no conclusion of value as to the relative merits of tracheotomy and intubation was possible with the present statistics.

Section in Military and Naval Surgery and Medicine.

The first paper read was by Dr. Robert Reyburn, of Washington, D. C., upon the question, "Are Wounds from Explosive Balls of such a Character as to Justify International Laws Against their Use?" The general conclusion of both the writer and those who spoke upon the question seemed to be that they were. Dr. H. H. Smith, of Philadelphia, mentioned the fact that President Lincoln had suggested that their use be discontinued in the war of the Rebellion.

Dr. Jeffrey A. Marston read an interesting paper upon "Age and Acclimatization of Soldiers in Reference to Service."

The best age for service, at least in India, was between twenty seven and thirty years. He stated that in India mortality was greatest from typhoid fever. It is most frequently fatal during the hot and cold seasons.

During the first year of a soldier's life he is likely to be attacked with a fatal form of pneumonia. The diseases, in their order of prevalence, are typhoid fever, hepatitis and heart disease.

The discussion which followed the reading of this paper fully endorsed its statements.

Several papers, in the absence of their authors, were read by title.

A very able paper was then read by Dr. Jno. Anderson, of London, on "Heat-Stroke in India."

The speaker referred to the labors of Dr. H. C. Wood, and then proceeded to divide his subject, in accordance with the severity of the disease, into ardent fever, heat apoplexy, and sunstroke. After describing the symptoms of each form, the author spoke emphatically against the use of alcohol, and gave his preference for a drink for soldiers to cold tea with lime juice. For medical treatment, the author highly recommends the hypodermic injection of a neutral salt of quinine. Perfect clearness of the solution is a point to be insisted upon. He had never seen tetanus result from these punctures. The reduction of temperature was difficult to explain. Possibly it arose from the action of the drug upon the cardiac ganglia.

Section in Laryngology.

The first paper was read by Dr. J. P. Klingensmith, of Blairsville, Pa., on "Hay Asthma."

The speaker was inclined to make local irritation, hypertrophies, deflected septum, etc., the starting point, and pollen, etc., exciting causes.

At the afternoon session, Dr. N. Rankin read a paper on "Some Remarks upon the History of Rhinology."

Section in Psychological Medicine.

The opening paper was on "Miliary Aneurisms," by Dr. E. C. Spitzka, of New York. The speaker reported a case in point, and also one of deformity of the brain.

The next paper was upon "Remissions and Intermissions in Insanity," by Dr. Daniel Clark, of Toronto. This paper provoked considerable discussion, for the most part adverse to the author's views.

Dr. Bower, of Bedford, presented the next paper, upon "Occupation for the Insane in Asylums for the Private Class in England." All sorts of general house, garden and farm work were done by the patients. The most suitable work has been copying of legal documents.

At the afternoon session the first paper was read by Dr. Theo. W. Fisher, of Boston, Mass., on "Monomania and Modern Equivalents."

Two papers were then read upon "Classification of Insanity," and one upon "The True Nature and Definition of Insanity." The latter by Dr. Hughes.

Section in Surgery.

Dr. John Homans read the first paper. It was entitled "Three Hundred and Eighty-four Laparotomies for Various Diseases." Among other good results he reported the cure of a case of tubercular peritonitis.

A paper on the question "When is Colotomy justifiable," was read by Dr. I. M. Matthews, of Louisville, Ky. The writer did not consider the operation justifiable when there was cancer three inches from the anus, nor in stricture not in reach of the finger, nor in aneurism, nor in cases of specific origin.

Section in Gynecology.

Thos. More-Madden, M. D., F. R. C. S. Ed., of Dublin, Ireland, presented the first paper, on "The Causes and Treatment of Barrenness." He presented a tabular statement of the causes of barrenness in five hundred and twenty-eight cases of sterility. The most frequent cause was found to be stenosis of the cervical canal. Of those due to this cause he reports the best results in three hundred and eighty cases. He advised cutting and simultaneous forcible expansion of the affected parts, followed by dilatation during the period of cicatrization. He then described the instruments he used for this purpose.

Dr. A. Reeves Jackson then read a paper upon "The Modern Treatment of Uterine Cancer."

The next paper was by Prof. Graily Hewitt, of London, England, upon "The Relations between the Changes in the Tissues and Changes in the Shape of the Uterus." In young women who have been inadequately nourished, there sometimes occurs about puberty a non-inflammatory softening of the uterus. This produces an abnormal flexibility, which in turn permits flexion. When subsequent hardening occurs the flexion is persistent.

At the afternoon session Dr. W. H. Wathen read a paper entitled "Rapid Dilatation of the Cervix Uteri." The writer presented instruments which he considered an improvement upon Goodell's modification of Ellinger's. He is in the habit of using this instrument in his office and dilating the cervix without general or local anæsthetic, to the extent of half an inch, and allows his patient to walk or ride home a few minutes afterwards.

Section in Dermatology and Syphilography.

The papers presented in this section were "Studies in Hirsuties," by G. H. Rohé, of Baltimore, Md.; "A New Method of Treating Diseases of the Skin Locally," by Dr. Valentine Knaggs, of London, England; "A New Method of Treating the Vegetable Parasitic Diseases of the Skin," by Dr. J. H. Reynolds, of Chicago, Ill. Dr. Knaggs's paper was a plea for the substitution of emulsions for ointments in the treatment of skin diseases. The former make films and are adhesive and protective. The following is a good base:

R	Paraffin molle.....	3 j
	Pulv. gum. acac.....	gr. clx
	Acid. borici.....	gr. xvi
	Aquæ.....	ad. f 3 j.

Stir until emulsified.

Bismuth, zinc and sulphur may be added to this when desired. All lint, etc., should be dispensed with.

Dr. Reynolds's paper gave a very interesting account of the author's method of applying parasiticide lotions by means of a sponge electrode wet in bichloride solution and applied to a diseased area, as in favus or ringworm of the scalp. A one per cent. solution of bichloride of mercury was used. Only three cases had been treated, but the result was encouraging.

Section in General Medicine.

Dr. Josef Koercsi, Director of Commercial Statistics of Budapest, Hungary, read a paper on "The Preventive Power of Vaccination." The paper is a critical study of statistics of vaccination. After very careful analysis, the author finds that the *mortality* of small-pox as distinguished from the *lethality* (by the latter term meaning the liability of those already sick to die) was greater in the non-vaccinated than in the vaccinated by *five hundred per cent.*, and this was due exclusively to the lack of vaccination. No influence of vaccination upon syphilis or tuberculosis was found. In a population like that of the United States, vaccina-

tion would annually save 120,000 lives, while the number of children dying of cutaneous diseases as the result of vaccination, etc., might make 300.

Dr. Whitmarsh, of London, read papers on "Vaccination and Pasteur's Treatment." The first was a plea for vaccination, coupled with an assertion of its dangers, and a statement that sufficient caution was not exercised by the Government of England in procuring proper virus. The second paper was a criticism upon Pasteur's method. He suggested trying Pasteur's method upon convicts, as was done with small-pox fifty years ago, allowing them the choice between their sentence and becoming the subject of experimentation.

Dr. Leale remarked that he had never seen or had reported to him a single case of hydrophobia, though he annually saw many thousand children, hundreds of whom had been at different times bitten by dogs.

Section in Obstetrics.

The first paper was by Dr. J. C. Cameron, of Montreal, Canada, upon "The Influence of Leukæmia on Pregnancy."

The author's case showed an hereditary tendency in the disease. The disease was apt to begin in the latter part of pregnancy. Successive pregnancies occurred during the progress of the disease. An interesting fact was the determination that red blood corpuscles were lost in the placenta, being in the normal quantity in the placental artery of the child, but diminished in the placental vein.

Professor A. Charpentier read the next paper, upon "Experimental Uræmia." By injecting urea into the blood of gravid animals, he found that death of the fetus occurred before death of the mother.

Dr. W. T. Lusk read a paper upon "The Prognosis of the Cæsarean Section." He thought that the brilliant results obtained abroad were due to the fact that they recognized better the proper time for doing the operation. The author was strongly in favor of Cæsarian section as opposed to craniotomy, even in pelves with a conjugate of three inches.

Dr. M. Säger, of Leipsic, Germany, followed with a paper, which was read in abstract, upon "The Cæsarean Operation." His operation was to be preferred to Porro's when the child was living, and could not be delivered by any other operation; or, when the child was dead, and could not be delivered by craniotomy or embryotomy, or only with extreme danger to the mother.

He attributes the mortality obtained in America to delay.

Dr. W. H. Wathen, of Louisville, Ky., read the next paper, upon "Abdominal Section for Removal of the Fœtus." He favored section as opposed to craniotomy.

Section in Otology.

The first paper was read by Dr. T. E. Murrell, of Little Rock, Ark., on "The Peculiarities in Structure and Diseases of the Ear of the Negro." He referred to true negroes, not mixed races. He finds that negroes are less affected by ear troubles than the white races, and that there are marked anatomical peculiarities belonging to their ears. The subject gave rise to quite a diversity of opinion in the discussion.

The next paper was read by Dr. Jno. F. Fulton, of St. Paul, Minn., upon "Primary Inflammatory Disease of the Mastoid Antrum." The disease is extremely difficult of diagnosis, but pain of a stinging, throbbing, tearing character, is apt to be constant. The diagnosis is rendered almost certain if a swelling occurs behind the ear *late* in the attack.

Other interesting papers presented and read were, "Indications for Artificial Opening of the Mastoid Process, and Best Methods for Closing the Same," by Dr. G. E. Frothingham, of Ann Arbor, Mich.; "Inherited Syphilis as a Factor in Suppurative Inflammation of the Middle Ear," by Dr. Robert Tilley, of Chicago; "Cerebro-Spinal Fever as a Cause of Deafness," by C. M. Hobby, of Iowa City.

Section in Physiology.

Dr. W. D. Halliburton, B. Sc., of London, England, read the opening paper, upon "Comparison of the Coagulation of the Blood with Rigor Mortis," in which he pointed out the resemblances between the formation of fibrin and the production of myosin. There were, however, important differences.

The second paper was read by Dr. T. W. Poole, of Lindsay, Ontario, whose subject was "The Necessity for a Modification of Certain Physiological Doctrines Regarding the Inter-Relations of Nerve and Muscle." The author held that spasm or contraction of involuntary muscles occurred not when their motor nerves were stimulated, but when they were cut, paralyzed or dead.

Section in Ophthalmology.

At the Afternoon Session, Dr. A. Mooren, of Düsseldorf, Germany, read a highly interesting and instructive paper upon "The

Simplest Method of Cataract Extraction," based upon an experience of 5,019 extractions since he began practice in 1855. He used boric acid as an antiseptic wash, and cocaine as a local anæsthetic. The cut is made with a Graefe knife downwards, the eyeball being fixed with simple forceps. Abandon friction if the patient is restless, and deliver the lens by gently stroking the eyeball. Subsequent treatment consists of a light dressing fastened with adhesive plaster.

Dr. N. Manolescu, of Bucharest, followed with a paper on "Cataract Extraction without, as Compared with Extraction with, Iridectomy," in which he expressed the opinion that the combined operation was more trustworthy.

In the discussion that followed a good deal was said with regard to the propriety of the simple or combined operation. The general opinion seemed to be that no rule in regard to the matter could be laid down.

Surgical Section.

At the afternoon session, abdominal surgery was first under discussion. Subsequently, Dr. Donald Maclean, of Detroit, Mich., read a paper on "Three Cases of Surgical Disease of the Kidney with an account of Operations performed for their relief, the Complications which arose, and the Results." He reports these cases with two recoveries and one death, the latter a baby 22 months old.

A paper by Sir Thomas Longmore, on "The Advisability of Providing Soldiers in Service in the Field, with some Form of Preliminary Dressing for Wounds," was read in abstract by Dr. Marston.

The author stated that a preliminary dressing for wounds was supplied now to the German soldiers, and had been in use in the British army since the Crimean war. He recommended a dressing of his own device as compact and complete.

A paper on the same subject by Esmarch was read by Dr. Stern, of Philadelphia.

Dr. Neudörfer's paper on "The Present Standpoint of Antisepsis and the Best Mode of its Application in War," was read by title.

Next on the list came a paper by Dr. B. A. Watson, of Jersey City, on "Primary Treatment of Gunshot Wounds." The writer advised the removal of all foreign matter from the wound, and then the occlusion of the wounds of entrance and exit with aseptic bandages.

The following papers were also read :

"The Importance of the Government Securing and Preserving Vital Statistics in the Army and Navy for the Benefit of Subsequent Applicants for Pensions," by Eli A. Wood, Pittsburg, Pa.; and the "Importance of International Regulations for the Medical Treatment of Prisoners of War," by D. S. Lamb, Washington, D. C.

Section on Laryngology.

Dr. Lennox Browne, of London, read the first paper upon "Recent Views as to the Pathology and Treatment of Tuberculosis of the Larynx."

In the early stages of the disease high attitudes by the sea or in a piny region are of the greatest importance. Inhalations of turpentine (vaporized), oil of eucalyptus and menthol are useful.

At the Afternoon Session, a paper for special discussion was read upon "Recurrent Hemorrhages of the Upper Air-Passages," by Dr. Wm. Porter, of St. Louis, Mo.

The next paper was one by Dr. W. E. Casselberry, of Chicago, on "Treatment of Laryngeal Papillomata." If the tumor is small, forceps are best. For large tumors, curette followed by cautery is used.

Dr. E. L. Shurley, Detroit, Mich., gave an abstract of his paper on "The Diagnostic Differentiation of Recent Tuberculous, Specific and Rheumatic Laryngeal Diseases."

The next paper was one upon "Chronic Rheumatic Laryngitis," by Dr. E. F. Ingals, Chicago, Ill. Treatment is by astringent and cleansing sprays, and internal use of alkalies or aromatic oils.

The last paper was read by Dr. A. B. Thrasher, of Cincinnati, Ohio, upon "Resorcin in the Treatment of Nasal Catarrh." He claimed for resorcin the same results as for cocaine, but without loss of the normal functions.

—A citizen of Gainesville, Ga., whose pet cow suddenly showed symptoms of going dry, consulted a cow doctor, who decided that she had the "hollow tail," and split the tail, inserted a quantity of salt and turpentine and bound it up. Going out the next day to see how the cow was getting along the owner caught a half-grown pig, which he had kept in the same lot, busily engaged in sucking the cow, and this accounted for the falling off of milk. He at once took the bandage off the unfortunate cow's tail.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Initial Symptoms of Tabes Dorsalis.

On account of the extraordinarily great importance that is accorded to the diagnosis of tabes dorsalis in its earliest possible state, Karger (Inaug. dissert. Berlin, 1887) has set himself the task of studying with particular diligence the initial symptoms of the disease. For this purpose he made use of the rich material of Mendel's polyclinic, and investigated 117 cases which he observed there, of which number he communicates 70 of the most characteristic in a table at the conclusion of his thesis.

The following are the author's results in detail:

1. The diagnosis of tabes offers but few and uncertain persistent points; although a very frequent etiological connection exists between tabes and syphilis. The author could establish with certainty the previous existence of syphilis in 53 per cent. of the cases.

2. *Disturbances of sensibility* are characteristic of the incipient stage. These are lancinating pains, next paresthesias of all kinds, such as the feeling of numbness, especially in the lower extremities, and the girdle-sensation; further, slowness of perceiving sensations and Romberg's symptom, which is of especial significance and can be pretty constantly demonstrated. This, however, the author marks as an anomaly of sensibility, not as a symptom of ataxia.

3. *Disturbances of vision.* Diminution of the sharpness of vision, concentric contraction of the field of vision, amblyopia, amaurosis, depending upon atrophy of the optic nerve (35 per cent. of the cases); further, slight transient but returning paralysis of the ocular muscles, which, according to the muscles concerned—oculo motor, abducens, trochlear (rarely)—lead to different anomalous positions of the eye. Very characteristic is the reflex rigidity of the pupil in 66 per cent. of the cases, conditioned in part by paralysis of the sphincter and in part by

4. *Reflex disturbances.* The author comes to the remarkable result that the patellar reflex, which has been noted as absent pretty nearly without exception, was preserved eight times in his one hundred and seventeen cases and therefore preserved oftener than other statistics show. Of other reflex disturbances there are to be noted: Diminution of the

bladder reflex—chronic disease of the bladder without palpable local disease should awaken suspicion of tabes—diminution of the sexual reflex (impotence), while the abnormal increase of these visceral reflexes belong to the rarities. Other rare symptoms are gastric and cephalic crises, tabetic diseases of joints.

The author comes to the conclusion that complaints of a vague kind, such as nervous pains, troubles on the part of the visual apparatus or of the bladder, in no way justify the physician in making the diagnosis of tabes; but that they must continually challenge him to an accurate investigation of other tabetic symptoms, inasmuch as the characteristic objective symptoms, such as loss of the patellar reflex, Romberg's symptom, reflex rigidity of the pupil, cause no subjective troubles. In conclusion, the author cherishes the proper belief that in an early diagnosis, the chances for rational medical treatment and its successful result, are much more favorable.—*Allgemeine med. Central-Zeitung*, August 3, 1887.

Affections of the Heart in Tabes Dorsalis.

Among the manifold visceral complications which not rarely attend typical tabes dorsalis, and which seize upon nearly all parts of the viscera with peculiar nervous attacks (crises), Leyden of Berlin thinks those that effect the heart are ordinarily the least studied and described. Nevertheless the heart and its nerves remain by no means unaffected.

In spite of the relatively frequent association of valvular affections with tabes dorsalis, according to the author it is not quite possible to assume an intimate connection between the two, and to regard the first as an atrophic shrinking process affecting the valve. Both diseases are of themselves much too frequent to permit such a conclusion. Of greater interest according to the author, are the heart affections hitherto only rarely observed, which Leyden has already mentioned in his article upon tabes dorsalis in Eulenberg's *Real Encyclopaedia*, and in addition to which he has since had opportunity to make some further observations.

These attacks are characterized by oppression in breathing, and pain, and a feeling of anxiety that arise and disappear suddenly. They bear an indisputable resemblance to angina pectoris; they can therefore be referred to a neuralgic participation of

the vagus nerve. As in general all paroxysms arising in tabes affect sensitive and sympathetic nerves, so also these attacks of the heart-nerves have a different intensity and duration. These attacks in question are extraordinarily violent and can even be accompanied with such danger as to threaten life.

Basing his conclusions upon reported observations (for which see the original), the author holds that in the course of tabes dorsalis the heart is affected by attacks which are analogous to the gastric, laryngeal, and bronchial crises. They arise with painful paroxysms of changing violence. The complex of symptoms evidently corresponds with angina pectoris. The sufferers go about with pain in the neighborhood of the heart which not rarely radiates into the left arm. With this is joined a feeling of oppression in the breathing, at times a high degree of anxiety, suffocation, a feeling of annihilation, as well as vertigo, faintness, and often irregularity of the pulse during the attack.

From its connection with tabes dorsalis, it is to be concluded, according to the author, that we have to do with neuralgic attacks within the sphere of the heart-nerves, and therefore with nervous angina pectoris, which with Romberg, can be called neuralgia of the heart. Although the symptoms are not very violent they can connect themselves with threatening failure of the heart. Leyden thinks it cannot be easily explained how this arises, inasmuch as sufficient findings of autopsies are not yet in existence. In a case of Vulpian's (*Revue de Méd.*, 1885, page 60) there were no striking post mortem phenomena recognizable in the heart. But that the vagus nerve can be attacked by the degenerative process, is proved particularly by the investigations of Oppenheim, who found this nerve markedly atrophied in a case attended by violent gastric crises. But according to the author, it could be suspected that such a profound degeneration of nerve fibres must call forth not only gastric crises but also cardiac attacks, especially since Oppenheim mentions that gastric crises are attended by severe pain in the præcordium and pains radiating into the left arm. In Vulpian's case, the attacks connected themselves with angina pectoris just as gastric crises do. Also other symptoms that are concerned with the cardiac nerves in gastric crises are observed, even the sensation of præcordial pain, and acceleration and irregularity of the pulse. In the author's cases, cardiac attacks are proved to occur independently of gastric crises.—LEYDEN. *All gemeine med. Central-Zeitung*, July 30, 1887.

The Curability of Tabes Dorsalis.

Babinski, chief of one of Charcot's wards, has made a communication to the *Société de Biologie*, which apparently shows recovery from tabes. Most neurologists, among whom we may mention Leyden, Rosenthal and Hammond, seem to be very sceptical in regard to the possibility of recovery, or even improvement, in this disease. On the other hand, Strümpell and others admit, at least, that pauses may occur in its development. Brown-Séquard shares this opinion, and goes still further, for he admits the possibility of a cure. Babinski rests his opinion on three observations, one of them with an autopsy.

The first case was that of a male of 39, who came under Charcot's care in 1875. Charcot made out typical tabes, and sent him to a bath (Lamalon). The patient took the cure for ten successive years, with an evident improvement after each season. In 1885, the patient had as remaining symptoms only very mild and infrequent attacks of pain, and has continued to the present time in this condition. In the second case the patient, a physician, began at the age of 35 to notice shooting pains in the legs, which increased in severity, and made it necessary for him to give up practice. In 1871, three years after the first symptoms appeared, he consulted Duchenne and Charcot. Both pronounced the disease tabes. The condition became worse until 1881, from which time an improvement made itself manifest, and in May, 1887, he had as remaining symptoms only infrequent radiating pains, absence of tendon reflex and a small hyperæsthetic spot.

The third patient, in 1852, at the age of 38, was affected by diplopia, lasting several weeks. Then weakness appeared, and the patient suddenly went blind six months later. At the same time lancinating pains appeared. In 1869 the patient, a female, was admitted to the Salpêtrière. Atrophy of the optic nerves, severe gastric crises and pains in the upper and lower limbs were made out, but no incoordination of the gait. In 1876, the presence of Westphal's phenomenon was recognized. In 1878 the lancinating pains and gastric crises had disappeared, but the blindness persisted. In 1886 the patient died of pneumonia.

Examination of the nervous system showed that in the lumbar region the posterior columns were sclerosed, especially the parts lying nearest the meninges. The medullary fibres were much less numerous than normal. The pia mater was thickened in the neighborhood of the posterior columns. In the dorsal

region sclerosis affected the columns of Burdach and Goll. In the cervical cord sclerosis predominated in the column of Goll, but spread to some extent in the adjoining tissue. In the posterior columns the number of medullary fibres was much reduced, and in the optic nerves they had almost disappeared, there being little left besides connective tissue and blood vessels. The autopsy, therefore, proves the diagnosis of Charcot, who had repeatedly demonstrated the case as one of recovery from tabes ("extinguished tabes").—*Deutsche med. Wochenschr.*, No. 28, 1887.

Ointment for Impetigo.

Liebreich recommends the following:

R	Acid. salicyl.....	gr. xv
	Pulv. zinci oxidl.....	gr. clxxx
	Pulv. amyli.....	gr. clxxx
	Lanolin.....	3 vj

M. For local use.

L'Union Médicale du Canada, July, 1887.

Typhus Bacilli in the Blood.

The results of investigations of the blood for typhus bacilli have been contradictory, but Ruetimeyer approaches the question with the employment of all necessary caution. The blood was taken from the spots of the eruption. Of six typhus cases, one in the first week and five in the second, sixteen original cultures were made from thirteen different spots by about fifty-five punctures, and were put into test tubes; fifteen of the original cultures remained sterile and only in one culture from two punctures there developed itself in the course of some days, a small grayish spot, which the microscope showed to consist of bacilli, showing the character of typhus bacilli. The results are of general interest, but for diagnostic purposes can only apply to a few cases.—*Deutsche Medizinisch-Zeitung*, August 8, 1887.

The Bark of Condurango in Diseases of the Stomach.

Condurango has been considered for some time as endowed with remarkable properties in cancer of the stomach. A work by Dr. Riess, in the *Berlin. Klin. Woch.*, tends to relieve this remedy from the discredit into which it had fallen.

Supported by a great number of observations, the author declares that both the painful symptoms in diseases in which cancer of the stomach had been positively diagnosed, and even confirmed later by autopsy, have been removed by the use of condurango, and

that other affections of the stomach with a train of symptoms proper to cancer have been sensibly relieved, indeed even frequently cured. By the daily employment of 150 grs. of condurango continued for some months the appetite is seen very shortly to be improved, nausea and vomiting diminished or even cured, pain notably relieved or gone altogether, the strength and weight of the patient increased.

In all the cases the duration of life has been lengthened and in some the improvement has been so marked that the patients have been able to leave the hospital, considered as cured.

The changes which have been produced under the influence of the remedy upon the tumors in the stomach which have been accessible to palpation, have been especially remarkable. In a total of sixty-four cases, a sensible diminution of the tumor could be demonstrated seventeen times; in eight other cases these disappeared completely or nearly so, and in the other cases the tumor ceased to increase in the same proportions as formerly.

The use of the bark of condurango seems worthy of commendation in these cases. The author prescribes the decoction—150 grs.—f3 vj, to which five drachms of syrup are added.—*Revue Médicale*, June 1887.

Book Reviews.

Bar's Antiseptic Methods in Obstetrics. Translated by Henry D. Fry, M.D. Published by P. Blakiston, Son & Co., Philadelphia. Price, \$1.75.

Dr. Paul Bar is accoucheur to and was formerly interne in the Maternity Hospital, Paris.

While antiseptic midwifery has been much written about in the last few years, it is probable that the greater portion of general practitioners do not yet realize its importance. The primary object of the physician is to save and prolong life. Manifestly, any method of practice that will tend to insure life to the life giving mother is a great blessing to the nation.

The author devotes the first few chapters to a discussion of the germ theory in its relations to the puerperium, and to the most effective agents in combatting sepsis. The rest of the book is taken up with a discussion of the proper procedures in different obstetric operations. The chapter devoted to antisepsis in catheterization seems particularly good, though the whole book is readable throughout, and is full of useful information.

THE
Medical and Surgical Reporter.

A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

N. A. RANDOLPH, M. D.,
CHARLES W. DULLES, M. D., } EDITORS.

All contributions to the Original Department will be paid for when published; or 100 reprints will be furnished in place of payment, if a request is sent with the manuscript. Contributors should ALWAYS state which form of remuneration they desire: reprints, extra copies of the REPORTER, or cash.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Compendium and Pocket Record,	7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,

N. E. Cor. 13th and Walnut streets,
P. O. Box, 843. Philadelphia, Pa.

A correct statement of the circulation of THE MEDICAL AND SURGICAL REPORTER is published in each number. The edition for this week is 6,000 copies.

SPECIAL NOTICE TO SUBSCRIBERS.

Subscribers to the MEDICAL AND SURGICAL REPORTER, who have remitted payments to the former editor, and who do not find upon the wrapper of their journal a correct statement of the time up to which they have paid, are requested to notify the present publishers as soon as convenient.

ACCIDENTS IN PRESCRIBING.

In another part of this number of THE REPORTER we mention the case of a physician who has been, and perhaps is yet suffering distress and anxiety from the suspicion that he has made a mistake in prescribing which led to the death of his patient.

As the story is told, he gave a grain of morphine to a young man, with directions how it should be taken. The patient took the whole at a dose, and died. The doctor, who is now the sole survivor of the interview, says he charged the patient to put the powder in twelve spoonfuls of water and to take one spoonful of the mixture at intervals until he felt drowsy.

So far as this case is concerned we do not for a moment doubt the statement made by the physician. It is incredible that any medical man should give a comparative stranger a whole grain of morphine at a dose; and the method of repeated moderate doses is in such general use that the physician's account of the directions is the only one which seems probable.

None the less—it may be because of facts which we have not learned—the doctor we refer to is believed by some in his community to have made a mistake in directing how the morphia was to be taken, and the death of the patient is charged to him.

This unfortunate circumstance illustrates one of the perils to which medical men are exposed. Engaged in one of the most arduous occupations to which men can be devoted, with risks to their health, risks to their families, and risks to their property, they are continually subject to grave risks to their reputation. Suspicion and accusation of mistake and even of wrong doing is no uncommon portion of their lot. Doubtless physicians do make mistakes. Doubtless sometimes a weary man, worn with the laborious duties of his profession and exhausted with loss of sleep, perhaps anxious about the care of his family, does order one drug when he intends another, or a large quantity when he means a small one. But how rarely does this happen. The wonder is that it does not happen oftener, and that, if it happens, it should be regarded with so little charity.

There are, however, mistakes made through carelessness, and when this occurs to a physician he is no more to be excused for the consequences of his act than is any other careless man.

A third class of mistakes is due to misunderstanding. These mistakes are not hard to prevent, and ought not to occur. A few prudential measures, if practiced habitually, would probably secure this result. We will call attention to three simple rules which may prove useful if habitually followed:

1. Always inform a patient when it would be dangerous to take the entire quantity of a prescription at a dose.
2. Have the word

"POISON!" marked on the label of every prescription which would be dangerous if the whole were taken at a dose. 3. When drugs which may be dangerous are given or ordered, *write* directions instead of giving them verbally.

We recommend these precautions to our readers, and would be glad to give publicity to any others which their ingenuity may suggest.

THE UTILITY OF INTESTINAL ANTISEPSIS.

Dr. D. N. Kinsman has published an interesting paper in the *Journal of the American Medical Association* in which, on scientific grounds, he urges the utility of antiseptics in various intestinal complaints. Summing up the results of the researches of Bouchard and Damaschino, he attaches great importance in the pathology of intestinal affections to the phenomena of fermentation and putrefaction of which the intestinal canal is the seat, and of which the principal agents are certain micro-organisms. Products such as indol, skatol, phenol, divers ptomaines, are the result of the action of bacteria. The meconium of new born babes does not contain them, nor are they met in the normal discharges of nurslings. The urine of the newly born, and of infants nursed exclusively at the breast contains no indican; but as soon as the babe is fed on a mixed diet, then the numerous bacilli appear in their stools, and indol and indican in their urine. These bacilli, which are the cause of putrefaction, engender poisons which are normally destroyed, or stored up in the liver, excreted by the kidneys, and even by the intestines. When from any cause the functions of the liver are interrupted, the bile no longer being poured into the intestine and exerting its antiseptic action, these toxic products of bacillary elaboration (ptomaines) augment in the alimentary canal and poison the blood. The action of mercurials, which heretofore has not been well understood, is now made plainer in the light of these facts; they evidently play an antiseptic rôle, in arresting morbid fermentations and destroying bacteria. They also neutralize the ptomaines, and thus prevent self-poisoning, and by their

cholagogue effect on the liver they indirectly have the same result. In answer to the question: "How may one determine the necessity for intestinal antiseptics?" the writer remarks, that one indication is the presence of indican in the urine.

Dr. Kinsman in pursuance of his inquiries in this direction has made a series of experiments on the discharges of patients affected with cholera nostras and cholera infantum. He has invariably found in these stools enormous masses of bacilli, and the examination of the urine revealed the presence of indican. The green discharges of infantile catarrh of the intestines also contain bacteria in abundance, and here Dr. Kinsman's observations agree with those of Professor Hayem, who however claims to have isolated the specific bacterium which causes the green discharges.

It is worthy of note that the success which attends the antiseptic treatment of these intestinal affections—and the markedly bactericide agents such as creosote, resorcin salicylate of soda, corrosive sublimate seem to be more and more coming to the front in the therapeutics of intestinal ailments—confirms the views which have above been stated.

—A Health Department wagon, carrying a barrel filled with a solution of bromine, was driven along the excavations, and the chemical was sprinkled upon the upturned earth from large sprinkling cans. Mr. Bayles, President of the Board of Health, was present at 9 o'clock yesterday morning when the operation was in progress, and expressed himself as much pleased with the result. The odor of the mixture is rather pleasant, and it at once neutralized the bad smell from the dirt. At Twenty-seventh Street and Broadway, where some particularly foul earth lay exposed, a double dose of the disinfectant was applied, with the result that the offensiveness was wholly removed. The smell from the dirt is simply that of the gas which has escaped from the pipes, and which the pavement held imprisoned in the ground. Although several people complained of headache from inhaling it all day, it is not considered as very unhealthy. Several applications of the chemical were made during the day, and everybody was gratified at the marked change for the better.—*New York Sun*, August 18th.

NOTES AND COMMENTS.

Pachydermia Laryngis.

[The deep interest which has been aroused in the disease affecting the throat of the Crown Prince of Germany, must be our excuse for giving to the readers of the *REPORTER* a more extended description of the affection than that contained in the last issue.]

In opening his paper (read before the Berlin Medical Society) Professor Virchow remarked that it would ill become him to omit mention of the fact that his discourse was occasioned by the serious illness of the Crown Prince, which had so largely engaged public attention during the past few months. After alluding to his early studies of the anatomy of laryngeal growths, he described the boundaries of the pavement epithelium of the pharynx, as it extended upon the laryngeal structures; referring especially to the broad strip of pavement epithelium which passed over the region between the two arytenoid cartilages, and is thence continuous without interruption upon the vocal cords to their anterior extremities. He remarked that these sections of the larynx covered with pavement epithelium, when compared with portions of the digestive tract, showed a type approaching the cutaneous cells; that their characteristics were more or less cutaneous or dermoid. This was especially shown in the continuity of the flat epithelium of the skin, as it extended through the mouth into the respiratory and digestive tract.

The processes which form the objects of interest in this epithelial tissue partake largely of the character of chronic inflammation, in the course of which two morbid processes are especially noticeable, viz., *a.* localized swelling, generally limited to a single point; *b.* diffuse swelling. Both are excessive epithelial proliferation; in the first the cells do not change their type, but greatly increase as dermoid cells; in the second a diffuse proliferation of the superficial connective tissue, rather than of the epithelium, takes place. Both processes Virchow names pachydermia; the limited or localized form he terms "wart" pachydermia, or pachydermia verrucosa.

As a characteristic appearance on examination he finds at the posterior extremity of the vocal cord, where the processus vocalis of the arytenoid cartilage passes beneath the mucous membrane, at its emergence, a flat, oval swelling, which extends generally ob-

liquely from behind and above downward and forward beneath the border of the vocal cord. These bodies are symmetrical, and are not the scars of former ulcers, but epithelial layers closely adherent to the subjacent cartilage, and probably undergoing an erosive-like process. In addition to this there is a diffuse process which extends over the entire surface of the vocal cords, and consists of a superficial layer of grayish, thick material, which is made up of epithelial cells. Microscopic examination reveals a papillary structure covered with epithelia. A further extension of the disease is found in the inter-arytenoid spaces; this occurs, however, infrequently. In this condition an important feature is the occurrence of masses of hardened fissured tissue called rhagades, resembling the hardened portions of cutaneous callus. By the movements of the parts these masses wound the surrounding tissues, producing the appearances of cancrioid ulcers. He does not believe that an actual change into cancrioid occurs.

The most salient point of warty growths upon ordinary examination, is found at the middle and anterior portion of the vocal cords, and in the anterior angle where the vocal cords meet.

The best described form of pachydermia is that in which the papillary element is least well marked, the growth consisting of epithelia only. Such growths are generally called papilloma, a name which Virchow considers an absurdity; he shows how it is equally applicable to various tumors, and wishes that it was rejected from the literature as meaningless.

The essential characteristic of papillary proliferation in the larynx he considers to be the proliferation and hardening of the epithelial elements. Epithelioma is a much more appropriate name for the growth, which should be subdivided into hyperplastic and heteroplastic.

The diagnosis is difficult, and it can only be determined by anatomical examination whether the growth is heteroplastic or cancerous, or only superficial epithelial proliferation. The latter consists of a growth of the epidermal epithelium, amidst which the papilla grows. Such symmetrical growths are often found in connection with nests of epithelial cells. According to Virchow, the verrucosities of the larynx are of epithelial nature, and were formerly called condylomata, but this name is now reserved for another form of tumor. Another gross error in the classification of these growths has been in calling them fibromata; when sections are

properly made it will be found that in no instance does the connective tissue proliferate into the epithelium, but the growth is an epithelial proliferation. It is not difficult, by proper section, to study carefully the development of these tissues from nuclei, and from such observations the conclusion is reached that the disease pertains to the epithelium as such. Polyps may possess some of the characteristics of these growths, but not their combined peculiarities.

Virchow sums up his description as follows: In a certain portion of the larynx, caused by irritation similar to that which exists on the external skin, two kinds of proliferation may occur which resemble chronic inflammation; one produces a warty growth, and one a diffuse, even swelling, which attacks the entire superficies. These resemble markedly the warts and diffuse swellings produced by irritation of various sorts upon the integument, causing a local increase of tissue. (In illustration of the differential diagnosis of these growths, specimens of lupus and papillary cancer were exhibited.)

Virchow's criterion of distinction between the papillary wart and the papillary cancer is the absence or presence of epithelial elements in the connective tissue. He considers all growths benign in which the normal demarcation remains at the base of the epithelial layer. Every trace of epithelium in the connective tissue he considers suspicious. When he finds beneath the boundary line of epithelium spaces filled with epithelial masses, then he recognizes the distinctive characteristic which stamps the formation as cancerous.

Betol—A New Anti-rheumatic Remedy.

The substitutes for salicylic acid and its salts, which are continually increasing in number, appear to have received an important addition in the introduction of a salicylic ether of naphthol, which has been recommended by Sahli, who, our readers will remember, likewise introduced salol into the therapeutics of rheumatic affections. To this substance Sahli gives the name of betol, and like salol, which divides into salicylic acid and phenol, it splits up in the organism into salicylic acid and naphthol.

Betol appears to possess the advantage over salol in freedom from odor and taste. It contains, however, ten per cent. less salicylic acid than salol, and has likewise the disadvantage of possessing a much higher melting-point (203°F. , instead of 109°F.),

a point which is of importance, since the readiness with which such compound ethers split up into their component parts is dependent upon the lowness of their melting-point.

The conditions under which this remedy may be applied do not yet seem to be clearly established, since Sahli states that while he has in numerous cases of articular rheumatism, neuralgia, etc., employed betol with most successful results, in other cases its use has been followed by no improvement. In the latter instances, examination of the urine has shown, by the absence or faintness of the salicylic acid reaction, that the preparation did not become decomposed, as it must do to produce any therapeutic effects. Betol is readily soluble in fluid fats, and Sahli recommends the administration of this substance in solution in oils, with the hope of facilitating its decomposition, since it is known that the melting-point, and therefore the point of decomposition, is lowered by the presence of certain organic bodies.

Kobert, in the preceding number of the same journal, has likewise published a paper on this subject, in which he, almost without qualification, gives the preference to betol over salol, especially in its freedom from disagreeable after effects. Sahli regards this position as, however, not yet proved. He has given betol in amounts varying from 15 to 180 grains in the twenty-four hours, the latter in a six year-old child. In some instances he has found the most marked effects from the smaller dose, while in other cases the larger amounts have appeared entirely inert. He therefore thinks that in our present imperfect knowledge regarding this substance, betol cannot yet take the precedence over salol on account of its smaller percentage of salicylic acid and its more difficult decomposition; so, also, the substitution of the inactive naphthol for phenol is to be regarded as a disadvantage, since the action of salol is not to be attributed solely to the salicylic acid but also to the phenol, which especially appears to be of value in the treatment of neuralgia. Nevertheless, on account of the freedom from disagreeable odor and taste, betol appears to be well worth further study to establish the conditions in which it is of value and to determine the correct method of its administration.

Kobert, who describes this preparation under the name of naphthalol, found it very useful, and at least as valuable as other medicaments, in various forms of catarrh of the bladder, especially in gonorrhœal cystitis,

with alkaline decomposition of the urine. The urine soon became clear and acid, the formed elements in it were diminished in number, and the pains of the patients became easy.—*The Therapeutic Gaz.*, Aug. 15, 1887.

Glioma of the Retina, Convulsions, Extirpation of the Eye, Death.

Dr. Wood gives the following account of this case in the *North Carolina Med. Jour.*, August, 1887.

Mistakes in diagnosis, if thoroughly recognized and investigated, are capable of yielding valuable lessons to the practitioner. I have overcome my hesitation in making this case public, because I believe its narration may serve to teach the important lesson in diagnosis which I learned by it:

O. S., a boy not quite 3½ years of age, was brought to me for an eye trouble. The cursory examination I was permitted to make of the little patient, who had become peevish by frequent attempts to see his eye, revealed what I took to be glaucoma. The upper lid was prominent and slightly red, having the appearance of ptosis, but still under control of the patient. The globe was hard, but not stony hard, as described in absolute glaucoma. The interior chamber had the reflex of a glaucomatous eye. There was a great amount of constitutional disturbance and the patient was anæmic, and his appetite exceedingly capricious.

The history of the case as obtained from the mother was that when the child was eighteen months old, while at play, it was seized with a sudden pain in its eye, and came running to her saying he had "got some snuff in his eye." She examined it, but did not discover any snuff. The pain passed off in a short time, or at least he was easily pacified. It was not long after this occurrence that a relative visiting the house remarked upon the peculiar appearance of the child's left eye. As he said he "could look deep down into the eye — there was a small clear spot in it." This was about August, 1883, two years after the first symptoms were noticed.

The father of the child was not willing to have an examination made at the first visit, and he returned to his home leaving the impression on my mind that I had absolute glaucoma to deal with, and that nothing better could be promised than an iridectomy of the remaining eye.

On Tuesday, 5th February, 1884, seven months after he was first seen by me, the patient was brought again to me, a dis-

tance of ten miles. Shortly after his arrival he was taken with convulsions of a most violent character, as described by the friends present. I saw him two hours later, and, learning the condition of the patient from the messenger, I secured the assistance of my friend Dr. W. J. H. Bellamey, who kindly visited him with me. We found him in a state of coma. His lips were cyanotic and covered with frothy saliva; his complexion was cadaveric; his pulse was small and very rapid; his breathing labored. Temperature in the mouth was found to be 99° F. The left upper lid was perceptibly prominent; there was a hemorrhagic stain of the lower edge of the sclerotic; death seemed imminent. A hasty examination led us to the conclusion that the life of the child was threatened by the pressure of the globe, and extirpation was decided upon.

Chloroform anaesthesia was attempted, but the breathing was so irregular that it was found impossible and unnecessary. Artificial respiration had to be kept up during the operation. There was the usual amount of hemorrhage, which was encouraged. After the extirpation was completed the breathing improved and so continued until it became normal in a few hours. The justice of the operation on therapeutic grounds was thus demonstrated.

A few months after, the orbit refilled, and the growth was removed, the cavity being well filled with chloride of zinc paste, and treated for several days. The fatal ending was thus delayed only a few months, the parents of the child declining any further efforts to destroy the growth.

The history of this case covers a period of about three years.

Vaginal Hysterectomy.

The *N. Y. Med. J.* (July 30, 1887), publishes the following correspondence, which explains itself:

In an article on "Vaginal Hysterectomy." by Dr. A. P. Dudley, published in your journal for July 9th and 16th, credit is given me for three operations of complete removal of the cancerous uterus *per vaginam*, with one recovery. I desire to add to this number two cases in which I operated on February 2d and 23d, 1887, with recovery; also a third, in which I operated on the 19th inst., which has thus far progressed so favorably that I have no reason to doubt that the patient will recover. I am induced to ask you to publish this note partly because I wish to

place my improved results on record (six cases with four recoveries), and partly because I feel compelled to differ with Dr. Dudley in his recommendation of the lateral posture with Sims's speculum as the best for the operation. My last three operations were performed with the patient in the dorsal posture, the uterus being removed *in situ*, according to the methods of Fritsch and Leopold, with modifications to suit the case, perineal and lateral retractors being used only at the beginning of the operation, and occasionally later on. The duration of the operations did not exceed an hour and a half, and the recoveries were uninterrupted. I am convinced that increased familiarity with the technical details of this operation will enable us to achieve as good results, so far as immediate recovery is concerned, as are reported by Fritsch (60 cases with 7 deaths) and Leopold (48 cases with 3 deaths). Had I then been as familiar with the details of the operation as I am now, and had I performed it then in the dorsal posture, I am confident that I should not have lost my second and third patients, who died of shock from concealed hemorrhage, the Sims's speculum having hidden the bleeding points.

PAUL F. MUNDE.

In a paper read by Dr. A. Palmer Dudley at the third meeting of the Alumni Association of the Woman's Hospital, and published in your Journal for July 9th and 16th, entitled "Vaginal Hysterectomy in America," there is one statement that is misleading. In speaking of the extirpation of the uterus by abdominal section, Dr. Dudley says: "As early as July 25th, 1853, Dr. Walter Burnham, of Lowell, Mass., operated by this method, and was followed in August of the same year by Dr. Gilman Kimball, of the same city." This naturally conveys the idea that Burnham was the first successful operator and entitled to the credit of the same. This is contrary to fact. To Dr. Gilman Kimball belongs, and has been given, the credit of having been the first to operate with success after a correct and clearly determined diagnosis had been made. The case occurred in Vernon, Conn., and the operation was performed on September 1st, 1853, for the removal of a uterine fibroid. It was in every way a success, the patient being fully restored to health. A full history of the case was published in the "Boston Medical and Surgical Journal" in May, 1855. The case reported by Burnham and one reported by another operator in a neighboring city were cases of *mistaken diagnoses*. An operation

was undertaken in each case for the removal of an ovarian tumor, but resulted in the removal of a uterine fibroid, and in one case the operator did not know he had removed a fibroid until he was told so by a pathologist to whom it had been sent for examination. The accounts of the cases were published and widely distributed, but for some mysterious reason the error in diagnosis was not mentioned.

I will mention a few of the leading men who give the full credit of the operation to him to whom it belongs. Koeberlé, of Strassburg, in a pamphlet on "Extirpation of the Uterus," describes the case of Dr. Kimball as the first successful one on record. Bantock, of London, in an exhaustive article in the *British Medical Journal*, after reviewing the whole subject, unhesitatingly gives the credit of having been the first to operate successfully in this line of surgery to Dr. Gilman Kimball, of Lowell. Baron von Langenbeck, of Berlin, speaks of this case as having no precedent in surgical literature. Keith, of Edinburgh, also ascribes to him the full credit for priority in the operation. In a paper by Dr. T. G. Thomas, of New York, published in the *American Journal of Medical Sciences*, in 1876, reviewing the progress made in gynecology in this century in America, in speaking of the procedure, the author says: "In 1853 the first operation was performed in this country for this purpose by Kimball, of Lowell, the tumor weighing six pounds, and the patient recovering. Kimball has, thus far, performed ten operations, with four recoveries and six deaths." It is thus seen that the most eminent authorities, both at home and abroad, place the credit where it rightfully belongs, and it does not seem as if any one who knows the true history of the operation will presume to question the correctness of what is now acknowledged by the highest authorities on the subject.

IRA J. PROUTY.

Legal Responsibility for the Use of Forceps.

The following case tried before Mr. Justice Cave, at Guilford, England, July 21st, 1887 (*British Medical Journal*, August 13, 1887), is of striking interest in this connection since it explains an important medico-legal question and shows the difficulties which must attend this character of medical litigation.

In the case in question action was brought to recover \$2500 damages for alleged negligence, unskillfulness, and misconduct of the defendants in their treatment of the plaintiff's wife in and about her confinement.

The plaintiff, one Gibson, alleged that he engaged the defendant, Jeffries, to attend his wife in her confinement and that Jeffries negligently directed the defendant, Hills, to attend her; that Hills did not exercise a reasonable degree of skill or care and was guilty of gross neglect and unskillfulness in conducting the delivery, whereby the plaintiff's wife was seriously hurt, wounded and mutilated.

Hills alleged that the labor was difficult and that after waiting a reasonable time, and finding the pains ineffectual and the head jammed in the pelvis, he, having obtained the husband's sanction, proceeded to deliver by the forceps. He did so, considering her condition was one requiring such assistance to effect delivery. The perineal rupture was unavoidable and was not caused by any neglect on his part. To repair the wound he had inserted three or four catgut sutures and had given proper directions to the nurse to keep the patient quiet afterwards. On the fourth day after delivery Hills handed the case over to one Chapman, another assistant of Mr. Jeffries. Chapman gave evidence to the effect that he assumed charge on the fourth day; that he found the perineum deeply lacerated and the wound in a very bad state. He considered the forceps had been used too early in the case and too continuously, without giving the parts time to recover themselves, and that during the delivery the perineum ought to have been supported by the hand.

Mr. Jeffries witnessed that he had frequently engaged Hills before as his *locum tenens*, and that he had always given satisfaction.

Dr. Graily Hewitt stated that the plaintiff's wife had consulted him about the injury to her perineum four months subsequent to the birth of her child. He found the perineum had been torn, the injury extending into the rectum. Dr. Hewitt refused to operate upon the case when he learned that an action for damages had been commenced by the patient and her husband. Dr. Hewitt expressed the opinion that as to the forceps being used at the proper time, no opinion could be given unless after examination of the condition at the time; it was for the practitioner to judge of that. His further testimony was corroborated as to the correctness and skill of Mr. Hills' management of the case. The learned judge in summing up the case observed that medical practitioners were expected to bring to bear a reasonable degree of skill and care, otherwise they became liable.

The evidence showed that Chapman had quarreled with the defendant, Jeffries, and

his testimony was impeached. Three medical men, witnesses for the defence, alleged that it was impossible for them to say, unless present at the time of labor, whether instruments were properly used or not; and that to form a judgment on this point the state of the patient must be known and considered. The judge virtually instructed the jury to bring in a verdict for the defendants, which was accordingly rendered as follows: "For the defendants, but we think there was not sufficient medical supervision over the nurse in the after treatment."

It was shown by the evidence that Mr. Hills had failed to inspect the perineal wound and had left its attention to a nurse. As he resigned the case on the fourth day into Chapman's hands one may question whether the subsequent neglect was not as much attributable to Chapman as to Hills.

The case is instructive from several standpoints. *First.* The plaintiff denied Mr. Jeffries' right to employ a substitute in the management of the case, especially one less skilled than himself. *Second.* Whether the careless use of the forceps is not just ground for legal action. We think it is. *Third.* Mr. Hills was somewhat remiss in duty in not carefully closing the perineal tear.

Is it not incumbent upon the obstetrician to promptly discover the extent of this lesion, to confess the same and to attempt its repair by primary union? We think so. It was shown that the plaintiff had greatly suffered in health and in loss of money in consequence of this perineal wound. She was permitted to bear the results of a lesion which might have been corrected if not prevented by skillful treatment. According to the evidence the jury could not do justly otherwise than find for the defendants, but it seems to us at this distance from the case that the plaintiff had good ground for instituting a suit for damages.—*Maryland Med. Jour.*, Sept. 3d, 1887.

—How to cut glass with a pair of scissors is not new, but may be of interest to our readers. According to the "Pottery Gazette," glass may be cut under water with great ease, to almost any shape, by observing the following directions: The glass must be kept quite level in the water while the scissors are applied; and, to avoid risk, it is better to perform the cutting by taking off small pieces at the corners and along the edges, and to reduce the shape gradually to that required. The softer glasses cut the best, and the scissors need not be very sharp.—*The Western Druggist*, August, 1887.

CORRESPONDENCE.

Dentistry for the Country Practitioner.

EDS. MED. AND SURG. REPORTER :

Dear Sirs : In reply to the question which you have asked, how great a knowledge of dentistry a country practitioner should have, I cheerfully write the following, which seems to me to cover the most essential points :

The doctor, in either the city or country, should know when to lance a child's gums. This knowledge is by no means as easily mastered as is generally supposed.

In the first place, the time at which the teeth normally appear should be perfectly known. Then, when a child begins to drink and cries without any obvious cause, or has its bowels or stomach obstinately deranged in such a way as to defy treatment, the practitioner should lance thoroughly over the position of the expected tooth. The moment the enamel emerges from its bony bed and begins to press the gum upward, the stretched tissues should be severed at once in order to relieve the tension. The gum will grow together, but should be cut again as soon as the child shows any tendency to relapse into the condition marked by the symptoms previously stated. If this be done frequently, the gums will not become inflamed, and the operation will be attended with almost no pain. The mother of the child, who is with it constantly, with a little education will be able to tell when the time for lancing has come much better than the doctor. And what is more, she will be one of the firmest advocates of lancing it if it is done in the first instance at the proper time, as she will see her child transformed, in a few minutes, from a crying, feverish, restless baby to a quiet, restful infant. When the gum is bulging it is rather late for the operation, but the lancet should nevertheless be used at once. The cusps of the molar teeth can often be felt low down on the side of the gum shortly after they have protruded from the alveolar process, although the eye is able to detect nothing. The gum over the molars and canines should be lanced with a double cut diagonal to the line of the gums. The gums should receive a single incision directly over the incisors, which cut should in all cases extend directly to the tooth substance.

The practitioner should also know how to cure tooth-ache. To do this, he must know that tooth-aches are divided into two great classes.

First, those caused by irritation of the nerve of the tooth proper, and *second*, those caused by hyperstimulation of the nerves in the structures adjacent to the root. The first class can be cured in the course of half a minute by the use of the proper medicaments in ninety-nine cases out of a hundred. Oil of cloves, carbolic acid, tincture of aconite, creosote, chloral, camphor, cocaine and a number of other remedies have been used—sometimes one has failed, sometimes another; all are more or less inefficient.

About two years ago Dr. Randolph brought the drug called Lewinin, a petroleum ether extract of Klada Kava, to the notice of the dental profession. A ten per cent. solution of this, made with chloroform, acts in a manner similar to cocaine, but much more rapidly. At that time Dr. R. was kind enough to present some of it to me, and since then I have never failed to cure a tooth-ache of the first named class immediately by its use. If Lewinin is unobtainable, and it is quite expensive and difficult to get, cocaine would better be tried. The irritant which causes the tooth-ache of the second class in almost every case is gas generated in the pulp-chamber, which is forced into the structures around the tooth through the apical foramen. If a hole be bored into the pulp chamber with a fine spear-pointed drill, the gas escapes as soon as it is formed and, the irritant being removed, the pain subsides in a few hours. Syringing out the pulp chamber and painting the gum over the roots with strong iodine will hasten recovery. Of course one must be sure that it is a tooth-ache of the second class before applying this remedy. The diagnosis is easy to make. If a jet of ice-cold or very hot water be injected into the cavity and no immediate pain be caused, or, if the tooth is lifted above its neighbor, and hurts when bitten upon, do not hesitate to open the chamber at once; the pulp is dead and gas is being formed. If the water application just mentioned causes throbbing, use the medicaments. If the tooth-ache is still refractory, the desirability of extracting it is to be discussed.

This brings me to the third requirement, namely, that the doctor should know how to extract teeth. To do this in a satisfactory way he must have a knowledge of their anatomy and that of the adjacent structures, and a good set of forceps. The method of extracting teeth is not very difficult to learn, and may be summarized in the following way: If the blades of the forceps are not pushed well up there is danger of fracturing

the tooth. The upper incisors, upper and lower canines are removed by a twisting and vibratory movement. The lower incisors and all the bicusps, with the sixth and twelfth-year molars, are to be detached by a simple outward and inward movement. The forceps should be forced far up on the roots of the tooth, which should be thoroughly loosened before its removal is attempted. The upper sixth and twelfth-year molars should receive the outward movement first, in order that the palatine root may be loosened at once. The upper wisdom teeth are the easiest teeth to extract, and are extracted by one outward and backward movement. The extraction of the lower wisdom tooth is most difficult. It is usually removed by an outward and backward twist.

But after all, these directions, which are like the alphabet to every dentist, are very crude. It is necessary to feel the tooth and take it out in the direction where the least resistance is offered. Yours respectfully,

JOSEPH HEAD, M. D., D. D. S.

Medicine in Iowa.

EDS. MED. AND SURG. REPORTER :

Here in Iowa it is remarkably healthy just now, and these sweltering hot days find me getting lazy. In a recent number of the *REPORTER* is recorded a case of heart disease in the treatment of which I can see nothing remarkable except a display of good sense. I wish to report a case not because there is anything new in treatment, but to keep the case fresh in my mind as one that can be very promptly relieved by a proper medication, not by any new methods, but upon principles old and time honored:

Mr. W., aged 63, an Irishman of temperate habits and no family history of note, always a hard worker, for forty years a railroad employe, of late years a section foreman, about a year ago noticed that he was more weary than usual after his day's work, and later that his breath was getting shorter upon any unusual exertion. About a month ago I was sent for where he was at work, about ten miles from my office. I found him sitting up, breathing short, countenance anxious, face dusky, pulse 120, heart impulse weak. He had been unable to lie down at night for several nights. A doctor had seen him and said he had asthma, and prescribed for him, but with no relief; he had no fever, tongue furred and appetite poor; bowels constipated. A physical examination showed effusion in pericardium and in left pleura; no

oedema of feet and ankles as yet. He wished to be brought to the town in which I lived, where he could have better care and proper treatment, and I only prescribed some palliatives until he could get there. The next day I found beginning oedema of legs, all other symptoms intensified. I began treatment as follows: R. Calomel, grs. x; sodæ bicarb., grs. v; and in four hours to have a pill of elaterium, $\frac{1}{2}$ gr. every six hours until free and thorough purgation, and in the course of twelve hours the action of the bowels was decidedly brisk. Then the following: R. Inf. digitalis, $\mathfrak{z}$ viii; pot. acetat, $\mathfrak{z}$ s. M.—A tablespoonful every six hours. The elaterium was repeated every other day, and the digitalis mixture continued. On the third night after treatment was begun he could lie down and sleep all night, and has done so ever since. His appetite returned, and he gained strength steadily, and now there is no sign of oedema nor effusion in any of the serous cavities; his heart is acting strongly and steadily, and he takes no medicine except some laxatives. In cases of dropsy from heart disease, I have seen the most wonderful results with treatment on this line. In such cases we see the triumph of scientific medication. The tools are sharp and keen; if we know how to wield them the results will be very gratifying to both patient and physician.

St. Ansgar, Ia. A. D. BUNDY, M. D.

EDS. MED. AND SURG. REPORTER :

Dear Sir:—In a report in the *Public Ledger*, from your journal, you say that when a druggist fills a prescription, "just look over and lay down a quarter."

Now when you say "the chances are that the drugs in the prescription don't cost over a dime," you overlook the item of labor. The labor must be skilled under penalty of the law, and is worth remuneration. The rule adopted where I am employed is to charge for labor and use of apparatus at a rate of 50 cents an hour, and to add it to the value of the drugs.

H. F. BACKHUSTON.

Phila., Sept. 2, 1887.

[We are surprised that our amiable correspondent should have found anything but pleasantry in the item referred to.—EDS. REPORTER.]

Dr. Borchheim, a physician with an extensive practice in Atlanta, Georgia, committed suicide September 11, 1887. The cocaine habit is said to have been the cause.

NEWS AND MISCELLANY.

The Gait of a Criminal.

A curious study has been made by Dr. Peracchia of the differences between criminals and law-abiding citizens as exhibited by their walk (*La Riforma Medica*, No. 147, 1887). The author first made a number of observations to determine the conditions of normal progression, and found that in good people the right pace is longer than the left, the lateral separation of the right foot from the median line is less than that of the left, and the angle of deviation of the axis of the foot from a straight line is greater on the right side than on the left.

Comparing these results with those obtained from the study of forty criminals, he found that in the latter the pace was shorter than the normal, a fact which did not seem to coincide with the greater robustness or "toughness" of these individuals. The left pace was longer than the right, the lateral deviation of the right foot was greater than that of the left, and the angle formed by the axis of the foot with the straight line was greater on the left side than on the right. It would thus seem that, in general, the gait of a criminal betrays a marked preponderance of power of the left foot over the right—a true sinistrality. This also agrees with the discovery of Marro that criminals are often left-handed. The moral is, of course, to beware of a left-handed individual, for there is a possibility that he may not be of good moral character.

But this is not all. Dr. Peracchia has not only shown us how we may distinguish criminals in general, but has laid the beginnings of the differential diagnosis between various sorts of evil-doers. The following are the distinguishing characteristics which his observations have enabled him to formulate:

1. *Thieves*.—In those who are predisposed to appropriate the property of others there is a pronounced widening of the base of support, together with a very long step.

2. *Assassins*.—In those who have murder in their hearts the base of support is not as wide as it is in thieves, since the angle formed by the axis of the foot with the median straight line is less obtuse; but the sinistrality betrayed by their foot prints is very marked.

3. *Ravishers*.—Those whose tendencies are in the direction of rape may possibly be detected by a skilled diagnostician by the fact that they take short steps and have no sinistrality to speak of.

These discoveries are of a very interesting character, and if the criminal could be induced to walk before the honest man, instead of following him as he usually does, they might also be put to a practical use, for then good citizens could diagnose the rogue by his tracks, and might thus be enabled to escape robbery, assassination, or rape, as the case might be.—*Med. Record*, Sept. 3d, 1887.

Composition for Removing Ink.

A newly patented composition for the removal and erasure of writing inks or writing fluids from paper, cloth, and all other substances with which writing fluids or inks may come in contact, without injury to the paper or other substance, consists of the following ingredients, viz.: Four quarts of water, four ounces of citric acid, twelve to sixteen ounces of strong solution of borax, three-quarters of a pound of chloride of lime.

In preparing the composition, two quarts of water, which has been previously boiled and cooled, are taken. Four ounces of citric acid are added, and after the acid has been dissolved, six to eight ounces of a strong strained solution of borax are added, after which the whole may be put in a bottle or suitable receptacle. Two quarts of water, which has been previously boiled and cooled, are taken, adding thereto three-quarters of a pound of chloride of lime. The whole is well shaken and left to stand from four to six days, after which it is strained, and from six to eight ounces of a strong solution of borax are added, and the whole is placed in a separate bottle.

When it is desired to remove ink from paper, cloth, or other absorbent substance, the composition in bottle No. 1 is applied so as to thoroughly saturate the place occupied by ink, a blotter being used to absorb all waste moisture. The composition in the second bottle is then applied. By the combined use of the two fluids thus described, writing inks or other fluids will be immediately dissolved and removed from the paper, so that the latter may be again written on.—*Pacif. M. Rec.*, Aug., 1887.

The Crawford County Medical Society.

The trouble in The Crawford County Medical Society, which has existed for the last six years, and which resulted in the expulsion of Dr. John C. Cotton by the Society, has recently been decided in the Court of Equity of Crawford county. The decree of the court reverses the decision of the Medical Courts of the State, and restores Dr.

Cotton to his membership. The court holds that voluntary associations must be governed by their own laws, which in this case had been violated, in that the Society ignored the action of its own judicial body, which had exonerated the doctor, and proceeded to try the case itself, with a different result.

Cocculus Indicus.

According to Dr. Atkinson (*Virginia Med. Month.*, August, 1887), *cocculus indicus* is much used to increase the intoxicating power of beer, and the quantity of this adulterant imported into England is really enormous. Commonly, it is understood to be imported from the coast of Malabar for use among the tanners and dyers; but there is a so-called "extract" sold in casks, under the name of "bittern," which is said to be composed of this same *cocculus indicus*, with extract of quassia to add to the bitterness of the beer, with liquorice to impart color, and sulphate of iron to give an additional froth to the fluid. It is said that the copperas is especially useful in the manufacture of porter, or stout, as giving the peculiar flavor to porter and to half-and-half, when drunk from the pewter pot so common in ale houses throughout England.

Died in a Dentist's Chair.

A case of death in the dentist's chair occurred at Harrisburg, August 29. The victim was George E. Hoffman, book-keeper for the Foundry and Machine Works, aged 38 years. Mr. Hoffman went to Dr. M. M. Ritchie to have a tooth pulled, and previous to the operation there was administered to him a mixture of chloroform and ether. The operation was about over when Dr. Ritchie noticed that Hoffman's face had grown pallid and his limbs rigid. He placed him on the floor and tried all the remedies at hand, but without avail. Assistance was summoned, but after an hour's work Hoffman breathed his last. Dr. Ritchie thinks he died of brain trouble. A post-mortem examination will be held.

Deceased was a son of the late ex-Sheriff Hoffman and was at one time prominent in the politics of Northumberland county. He served for several years as a clerk in the State Treasury under Robert W. Mackey.

Death from an Overdose of Morphine.

Bristol has been in great excitement for four days over the manner of the death of William Morrow, a respectable young carpet weaver, 23 years of age. Half the town is up in arms, blaming the physician who attended the young man for his death, while the other half are as vigorous in their defense of the doctor.

There is not the slightest doubt but that the young man died from taking a one-grain powder of morphia. He had gone to the physician to get something to make him sleep. It was an overdose, but he was given verbal instructions as to its use. Coroner Silbert held an inquest, which was attended by hundreds. The jury's verdict was: "The jury find that William Morrow came to his death by an overdose of morphia, taken in mistake through a misunderstanding of the physician's directions."

Liability of Physicians.

In a recent case, involving a charge of malpractice, tried in the Supreme Court of Massachusetts, the presiding Judge in charging the jury used the following language: "Whenever men are called upon to act with dangerous agencies, the law holds them to some degree of criminal responsibility. If they are grossly careless or reckless and presumptuous, they are guilty. The same general principle applies to medical treatment. The prosecution must show not merely the absence of ordinary care, but gross carelessness, amounting to recklessness. A man is not to be convicted of manslaughter merely because of his ignorance. His ignorance is only important, as bearing upon the question, whether his conduct in the care and treatment of the patient was marked by foolhardy presumption or gross and reckless carelessness. The defendant is to be tried by no other or higher standard of skill or learning, than that which he necessarily assumed in treating her; that is, that he was able to do so without gross recklessness or foolhardy presumption in undertaking it. It is not necessary to show an evil intent; if by gross and reckless negligence he caused the death, he is guilty of culpable homicide." Accordingly it has been held that a dentist or surgeon using an anæsthetic is not bound to look for any but the probable and natural effects of the drug, and is not liable for results arising from the peculiar temperament or condition of the patient, of which he had no knowledge, although if

this were discoverable upon such an examination of the patient as reasonable skill and diligence require, the dentist or surgeon would be responsible for negligently failing to inform himself.

The fundamental idea on the subject is, where honesty, average intelligence, skill and learning are possessed and are applied to the treatment of the case, with ordinary diligence and caution, the physician is not liable for any mischance that may befall his patient. It is only where he has been culpable that he is liable in damages.

A physician treating a patient in good faith, to the best of his ability, is not criminally responsible for the patient's death, although caused by medicine administered by him; but a person ignorant of the uses and properties of a poisonous drug is criminally liable for the negligent use thereof.—

Hall's Journal of Health.

A Surgeon's Life.

[From the Autobiography of the late Dr. Gross.]

I have always held that it is impossible for any man to be a great surgeon if he is destitute, even in an inconsiderable degree, of the finer feelings of our nature. I have often lain awake for hours the night before an important operation, and suffered great mental distress for days after it was over, until I was certain that my patient was out of danger. I do not think it is possible for a criminal to feel much worse the night before his execution than a surgeon when he knows that upon his skill and attention must depend the fate of a valuable citizen, husband, father, mother, or child. Surgery under such circumstances is a terrible taskmaster, feeding like a vulture upon a man's vitals. It is surprising that any surgeon in large practice should ever attain to a respectable old age, so great are the wear and tear of mind and body.

The world has seen many a sad picture. I will draw one of the surgeon. It is mid-day; the sun is bright and beautiful; all nature is redolent of joy; men and women crowd the street, arrayed in their best, and all, apparently, is peace and happiness within and without. In a large house, almost overhanging this street so full of life and gaiety, lies upon a couch an emaciated figure, once one of the sweetest and loveliest of her sex, a confiding and affectionate wife and the adored mother of numerous children, the subject of a frightful disease of one of her limbs, or it may be of her jaw, if not of a still more important part of her body. In an adjoining room is the surgeon, with his

assistants, spreading out his instruments and getting things in readiness for the impending operation. He assigns to each his appropriate place. One administers chloroform; another takes charge of the limb; one screws down the tourniquet upon the principal artery, and another holds himself in readiness to follow the knife with his sponge. The flaps are soon formed, the bone severed, the vessels tied, and the huge wound approximated. The woman is pale and ghastly, the pulse hardly perceptible, the skin wet with clammy perspiration, the voice husky, the sight indistinct. Some one whispers into the ear of the busy surgeon: "The patient, I fear, is dying." Restoratives are administered, the pulse gradually rises, and after a few hours of hard work and terrible anxiety reaction occurs. The poor woman was only faint from the joint influence of the anæsthetic, shock, and loss of blood. An assistant, a kind of sentinel, is placed as a guard over her, with instructions to watch her with the closest care, and to send word the moment the slightest change for the worse is seen.

The surgeon goes about his business, visits other patients on the way, and at length, long after the usual hour, he sits down, worried and exhausted, to his cold and comfortless meal, with a mouth almost as dry and a voice as husky as his patient's. He eats mechanically, exchanges hardly a word with any member of his family, and sullenly retires to his study to prescribe for his patients—never, during all this time, forgetting the poor mutilated object he left a few hours ago. He is about to lie down to get a moment's repose after the severe toil of the day, when suddenly he hears a loud ring of the bell, and a servant, breathless with excitement, begs his immediate presence at the sick chamber with the exclamation, "They think Mrs. — is dying." He hurries to the scene with rapid pace and anxious feeling. The stump is of a crimson color and the patient lies in a profound swoon. An artery has suddenly given way, the exhaustion is extreme, cordials and stimulants are at once brought into requisition, the dressings are removed and the resusant vessel is secured.

The vital current ebbs and flows, reaction is still more tardy than before, and it is not until a late hour of the night that the surgeon, literally worn out in mind and body, retires to his home in search of repose. Does he sleep? He tries, but he cannot close his eyes. His mind is with his patient; he hears every footstep upon the pavement under his window, and is in momentary expectation of the ringing of the night-bell.

He is disturbed by the wildest fancies, he sees the most terrific objects, and, as he rises early in the morning to hasten to his patient's chamber, he feels that he has been cheated of the rest of which he stood so much in need. Is this picture overdrawn? I have sat for it a thousand times, and there is not an educated, conscientious surgeon that will not certify to its accuracy.—*Washington Star.*

A Court Physician Beheaded.

The Ameer of Afghanistan suffered not long ago from a boil on his neck and sought relief at the hands of his court physician. The latter ordered some sort of a salve to bring the boil to a head. Unfortunately the application caused the august patient considerable pain, and after a night of torture he sent for his physician and had him decapitated. Evidently the physician to the Ameer does not hold a sinecure.—*Med. Record*, Sept. 3, 1887.

Sagacity of a Chemist.

A case has recently been reported in Paris in which a chemist acted with consummate judgment, so much so that it may be hoped that the course of action he adopted upon the occasion will be followed as a precedent by his *confrères* in trade, and be borne in mind and imitated when circumstances seem to require it. A flower girl, smarting under the infliction of being deserted by her lover, who had avowed his intention to marry another woman, made a point of attending the marriage ostensibly for the purpose of disposing of her floral wares. In the midst, however, of the rejoicing after the ceremony she suddenly confronted the newly married pair, and quickly withdrawing a bottle from her basket violently threw its contents into the face of each. A terrible scene ensued, and the worst results were anticipated by the assembled guests, the belief being that the young couple would be blinded for life. Instead, however, of this woeful termination to an auspicious gathering, nothing more dreadful happened than what a pocket handkerchief was amply sufficient to relieve. The fluid, owing to the sagacity of the chemist, was only tinted water. The flower girl, in asking for sulphuric acid, betrayed a demeanor which suggested to the shopman the probable use for which the powerful agent was required, and hence a direful tragedy was frustrated; the faces of two persons still remain unseared, and a woman's revenge, for once, has been unsatisfied.—*Med. Press and Circ.*, Aug. 17th, 1887.

A Splenic Discord.

A ductless gland is the spleen
In left hypochondrium seen,
Oblong and small in size,
Dark bluish-red to the eyes,
But what is its function, I ween?

Parenchymatous body they claim;
Pathologists talk in this strain;
'Tis full of trabeculae.
Reposits the blood, "ye see,"
This anthropological drain.

"Hepar sinistrum," old Galen cries,
"Diverticulum sanguinis," Gray replies.
It's a check on phlogosis
And controls hæmotosis
By the law of osmosis,
Which nature denies.

Quæ manu potissimum curat—amen!!
Was suggested by Celsus, adopted by Senn.
Davaine found microbes enjoying the spleen;
By Laveran, malarial bacilli are seen.
If we treat by resection this organ—what then??

But malaria, like some venomous snake,
Vents *her* spleen on this function by shiver and shake.
Malpighian cells, in her humble opinion,
Can't absorb the miasma that's in her dominion,
Unless Rex Quininus takes old Ague Cake.

And so by exclusion, we'll end all confusion,
This gland *surely* aids the digestion.
If a duct could be seen
In some good little spleen,
How soon this would settle the question.

TINNITUS POETICUS ET PRÆTEREA NIHIL.
West. Med. Rep., Aug, 1887.

The Obstetrical Advantages of Otter Tail County, Minnesota.

Otter Tail, one of the frontier counties of Minnesota, bids fair to rival the Rotunda Hospital or the Allgemeine Krankenhaus of Vienna as a resort for aspirants for obstetrical advantages and greatness. Dr. T. G. Hutton, of Fergus Falls, writes us that there are now in that county living quadruplets one week old, living triplets eight months old, living twins born of a sixteen-year old mother, and a child twelve months old whose mother is now only fourteen and one-half years old. It may be added, for the benefit of those who may hesitate between Vienna and Otter Tail County, that the latter place is just as accessible as Vienna, and the cost of living is less. The only reasonable objection to the frontier county is that the vernacular is English; nevertheless, it contains, we believe, a large number of Germans.—*Journ. Am. M. Assoc.*, Sept. 3, 1887.

Diphtheria in a Little Town — Thirteen Deaths in Five Days at Lockport, with 200 Inhabitants.

A large number of people are suffering with black diphtheria at Lockport, a small town of 200 inhabitants on the Pennsylvania Railroad about sixty miles east of Pittsburg. Thirteen deaths have occurred within the past five days.

Recently an old viaduct which formed part of the State canal was destroyed by dynamite at that point, leaving stagnant pools of water, which it is believed, have caused the epidemic. The victims are said to be seized with black vomit, and usually die in two or three days.

OBITUARY.

DR. CHARLES WILLING.

Dr. Charles Willing, a well-known Philadelphian, and the great-grandson of Charles Willing, one of the early Mayors of the city, died on Wednesday evening, August 31, at Tockington, his summer residence, near Jenkintown. His death is said to have been due to nervous prostration. He was born in this city on October 26th, 1805. When a young man he entered the sophomore class of Harvard College, from which he graduated in 1825, graduating later on from the medical department of the University of Pennsylvania. Subsequently he continued his medical studies in Paris, but in after years he relinquished active practice.

Dr. Willing spent a portion of his early life abroad. In 1840 he was married to the daughter of Hon. Joseph L. Tillinghast, of Rhode Island. He took an active interest in many charities, and was connected with

a number of institutions, including Christ Church Hospital, the Philadelphia Saving Fund Society, the Philadelphia Library, and the Pennsylvania Institution for the Deaf and Dumb. He also held several important trusts, and was sole trustee for the estate of William Bingham. Dr. Willing's grandfather was Thomas Willing, the first President of the Bank of North America, and his father was Thomas Mayne Willing, of the firm of Willing and Francis. From his father, it is said, he inherited the old Willing mansion. The wife of the deceased survives him.

There have been no changes in the Medical Corps of the Navy for the week ending Sept. 10, 1887.

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, U. S. Army, from September 4, 1887, to September 10, 1887:

Major C. C. Byrne, Surgeon, detailed as a member of the Army Retiring Board in Washington City, *vice* Captain Washington Matthews, Assistant Surgeon, relieved. Par. 2, S. O., 208, A. G. O., Sept. 7, 1887.

Major R. M. O'Reilly, Surgeon, U. S. Army, ordered to proceed to Fort Niagara, New York, on public business, and upon completion thereof to return to his proper station, Washington, D. C. Par. 10, S. O., 205, A. G. O., Sept. 3, 1887.

Capt. H. O. Perley, Assistant Surgeon, ordered to accompany battalion of the 23d Infantry from Fort Wayne, Mich., to Chicago, to participate in the International Military Encampment to be held in that city in October next. Par. 1, S. O., 191, Hdqrs. Div. of the Atlantic, Sept. 8, 1887.

1st Lieutenant W. B. Banister, Assistant Surgeon, granted leave of absence for one month, with permission to apply for extension of one month, to take effect upon arrival at Fort Lowell, of Assistant Surgeon J. B. Girard. Par. 4, S. O., 91, Hdqrs. Dep't of Arizona, Aug. 29, 1887.

1st Lieutenant Wm. N. Suter, Assistant Surgeon, ordered to accompany battery "E," 3d Artillery, from Washington B'ks., D. C., to Philadelphia, on the 14th inst., to participate in the Military Parade during the celebration of the Centennial of the adoption of the Constitution, Sept. 15, 16 and 17, 1887. Par. 3, S. O., 191, Hdqrs. Div. of the Atlantic, Sept. 8, 1887.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, for the two weeks ending Sept. 10, 1887:

H. W. Sawtelle, Surgeon, granted leave of absence for fifteen days, August 31, 1887.

D. A. Carmichael, Passed Assistant Surgeon, granted leave of absence for thirty days, September 5, 1887.

J. B. Fattic, Assistant Surgeon, ordered to Cairo, Illinois, for temporary duty, September 6, 1887.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

THE PRESENT POSITION OF ANTI-SEPTIC PRACTICE.

BY D. BENJAMIN, M. D.,

Surgeon to Cooper Hospital, Camden, N. J., etc.

The advance and improvement in the practice of Medicine and Surgery for the past decade has not only equalled that of previous periods, but, as might have been expected, equals that of any other departments of Art and Science. Of all the improvements that have taken place during this time Antiseptic Practice is decidedly the most important. It marks, really, an epoch in the progress of our profession.

For this great boon let us never forget that we are indebted principally to M. Pasteur, who finally succeeded in establishing, after thirty years of tireless labor and marvelous scientific experimentation, his Germ Theory. One who reads in the original, or even in the translations of the conflicts which this man sustained, almost single handed, for more than thirty years, against the dogmas of the day, and against the fascinating "Ignus Fatuus" of Liebig, must be deeply impressed with the fact that Pasteur is one of the scientific giants of the 19th century.

By the assistance of the workers in the field of biology and pathology the germ theory has become an established fact, and is no longer to be placed in the domain of theory.

One of the first surgeons who was sufficiently advanced in Science to grasp the full

import of the subject, and apply it in his practice, was the progressive Lister, of Edinburgh, who fortunately persevered in spite of the jeers of his brethren, until success was won. It is much easier to sneer than to study.

Antiseptic practice is based upon the demonstration that putrefaction and decay are due to the presence and action of *living germs, or micro-organisms*, and upon the belief that many, if not all, of the contagious or infectious diseases are also due to the same cause. It consists in the use of such means as are calculated to destroy or exclude these germs as an element in disease and injury. The habit and methods of distribution of germs becomes at once one of the most important considerations, and should receive special study. While it may be admitted that many species of germs are constantly everywhere present in the air, it must be equally true that disease germs are not generally present in the air, but are very prone to confine themselves to limited localities; in other words, disease germs do not fly through the air so readily and extensively as is generally supposed. The more I have studied the subject the more apparent has become the fact that disease germs are for the most part carried by fomites, and as carriers of disease, liquids and solids are incomparably more to be feared than air. Why? Because rain and snow have considerable effect in precipitating them to the earth, and dry air desiccates them so rapidly beyond the point of vitality or propagation, as to be one of our best disinfectants. Germs do not seem to multiply when suspended in the air alone, but only when in contact with moist solids and liquids.

Air is not a good carrier of disease germs; they will not even pass from room to room in a house, if all the correct and proper antiseptic precautions are taken, as I have frequently proved by treating a case of contagious disease in a house where many young people resided without the disease attacking another person in the house. Notes of cases which I have prove that even the germs of small-pox will rarely cross a street, and even if they do it is probably through clinging to pieces of rag, paper, muslin, or insects, saturated with the discharges, and while light enough to be blown about by the wind, will, for a while, protect and foster the germs until they find lodgement in the system of some susceptible person.

While it may be admitted that some germs seem indigenous to certain countries—for instance, cholera and yellow fever, these diseases do not spread out through the air to other countries; they remain, if no sanitary efforts are made, in that locality for ages, and only follow the routes of commerce when they spread; in other words, are carried by solid fomites, or by streams of water; *e. g.*, typhoid fever. The habitat and method of spreading of the various contagions has, for many years, been to me an interesting study. I hope some of our pathologists will soon give us a special work on the subject.

Now, ordinarily, the air is free from the specific germs of disease, except in close proximity to a patient suffering from a contagious disease, or a "centre of infection;" and if the patient becomes affected sanitary science is becoming so accurate that the source can often be traced, and an uncomfortable responsibility, before unknown to the profession, is being thrust upon it. The visitors, the attendants, the physician, and his instruments, fall at once under suspicion; and I have already seen it asserted in prominent journals that a physician will be held responsible now at law in case of a complication of a septic character occurring in his patient where a proper regard had not been shown on his part for correct sanitation. Thus the responsibility is increased by the progress of knowledge and science.

The recent growth of the antiseptic practice is as rapid as the results are gratifying. Eleven years ago, when I was a student in the University of Pennsylvania, the germ theory was not taught in our colleges as a probably correct thing, or as essential to an understanding of the etiology or treatment of disease. It was ignored, if not positively opposed, by those who were then Professors of the Theory and Practice

of Medicine, even by the learned Dr. Alfred Stillé; and I vividly recall the feeling of trepidation that seized me when I came before him for final examination, and saw in his hand my thesis entitled "Contagia," in which I had supported the germ theory, to the best of my ability. To my surprise, when I attempted to apologize, he showed me written on the essay, in his own handwriting, "Clear, logical and convincing; honorable mention," and gave his permission for its publication, but the then editor of *The Medical Times* refused to publish it on the ground that the "germ theory was not tenable."

In 1876, Professor D. Hayes Agnew had shown us at one of his clinics the elaborate method of Lister, and made some trials of it which were hardly considered entirely satisfactory, but were very encouraging.

Dr. Goodell, in speaking of the germ as a cause of disease, said, "We will not worry about the cause so long as we have the treatment." Dr. R. J. Levis soon after this time read a sarcastic poem before the Camden County Medical Society, about "one Lister, who carbolized wounds to a blister." All these professors now either teach the theory or endorse the antiseptic practice that has sprung from it.

At that time (ten or twelve years ago) there were, to my knowledge, only two men in the profession in New Jersey who seemed to understand and advocate the germ theory, namely, Dr. J. M. Ridge and Dr. Franklin Gauntt. Even so learned an authority as Dr. E. M. Hunt deprecated the theory, and declared before the State Sanitary Association, so late as the session of 1884, that the word "germ" was an unfortunate one, and should not be used as expressing the cause of disease, which was an unproved theory. He now declares before the same Society that communicable diseases may arise from hybrids, and he that would sterilize the system against the culture of this destructive plant-life (See Report of State Board of Health, 1886, page 231).

The methods by which a case may become infected are numerous and difficult to trace, and the profession has a great deal to learn on this subject. To illustrate this truth let me relate a few instances that have come under my own observation: Two or three years ago, in making a secondary amputation, one of the physicians picked up a sponge out of a pool of the gangrenous discharge, and mopped out the stump as I was about to close it again. Not long ago I met a physician in consultation in a most malignant

case of phlegmonous erysipelas. After he had squeezed from the numerous sinuses a great deal of thick pus he followed me to the door of the sick room, and with his hand unwashed and well smeared, took hold of my overcoat and rubbed his fingers down my bosom with decided pressure. I had the coat on at the time and I was afraid to wear it any more.

Again, a year or two ago, in consultation at the bedside of a child suffering with grave scarlet fever, one of the physicians, after throwing back the quilt, sat down in the bed and leaned on his elbow in it. He was rapidly making visits that day, and said there was a great deal of scarlet fever in his practice!

Again, not long ago, a physician consulting with me in a case of malignant scarlet fever, in a small room, with little ventilation, after being in the sick room about twenty minutes, put his hat on, filled as it was with the infected air, and started to make another call in the neighborhood, when I called his attention to the fact that he would let that hat full of infected air out into the next house he visited. He seemed surprised, and said he had never heard of such an idea, but he realized the possibilities.

Lately, again, I noticed a physician holding back the flaps in an amputation, although his finger nails were black with dirt.

Again, I was present and heard an old nurse say to a physician, who had her pour a long continuous stream of water over his hands as he washed them with carbolic acid soap, before examining a labor case, that she had always before seen doctors wash their hands in a basin, and after taking them out of the water thus contaminated, wipe them on a towel, and immediately make the examination. If the attention of teachers of our medical schools is properly directed to these things, the student will be taught to think of them. It should not be forgotten that in hospitals, and more especially in private houses, those who handle and work with the sick, with suppurating wounds or loathsome diseases, generally handle the chairs and furniture and door knobs, and especially the hand-railing in the stairways. The physician's finger is no longer positively aseptic after touching these things until it is resterilized.

I have now treated in private practice over three hundred cases of labor without a death, and only in one case was there marked septicæmia. I have also a record of eighty cases of compound fracture, with but one case of blood poisoning, and this case recovered. These favorable results I think are due

largely to a constant regard for the principles of antiseptic practice.

Dirt is not necessarily infectious; it cannot be, unless it happens, which is not often the case, to contain the specific virus of a disease; and this explains why so many thousands of wounds made by dirty machinery, on dirty people, and treated by surgeons or people who know nothing of antiseptic practice, have got well without septicæmia.

Before the introduction of the antiseptic practice, 60 per cent. of the deaths in cases of compound fractures were due to blood poisoning, and the rate of mortality from blood poisoning is now said by Dr. Denis to be reduced from 60 per cent. to a figure which is represented by a cipher.

Here is a result worthy of the admiration of all mankind; a realization that startles even the most hopeful of the profession, and causes one's pulse to bound with pleasure. What attainment in all the annals of medicine has excelled this? Sixty per cent. of the death rate wiped away by the solid advance of science in a single but great department of surgery. Is this not glory enough for one decade? Let us mark the epoch and erect a monument which generations yet unborn shall look upon with grateful pride.

All the leading hospitals of the world have adopted the antiseptic practice, and a most complete and excellent system for its thorough application has been adopted by the Prussian Government for its army and navy, the application of which is obligatory.¹

The adoption of the system is now absolutely necessary in private practice by any physician, who assumes the responsibility of a case, and this is the present position of antiseptic practice.

The following is a list of articles for an outfit for private practice recommended by Dr. G. H. Kirwan:

With reference to the cost of dressings, antiseptic dressings are in reality cheaper than ordinary wound dressings. The list here given contains all articles necessary for carrying out the principles and obtaining the extraordinary results claimed for antiseptics in wound treatment, and can be obtained at a cost of five dollars.

1. Bottle of compressed tablets of bichloride of mercury, each containing 7.3 grains, so that one dissolved in a pint of water will make the standard one to one thousand solu-

¹ See *Surgeon's Pocket Book*, Surgeon-Major J. H. Porter, 1887.

tion.² These tablets are readily soluble, and are much more reliable as well as more convenient than carrying a solution.

2. A soft rubber bag fountain syringe, capacity one gallon, with six or eight feet of hose attached with adjustable tubes.

3. Violin strings, to be obtained from any music dealer, four different sizes being all that are needed. They are saturated in oil of juniper for twenty-four hours, which removes the animal oil; then kept in a bottle of stronger alcohol, and saturated in the standard solution of bichloride when required for use, and are used for ligatures, sutures and capillary drainage. When needed for the ligation of large vessels they are made stronger and less readily absorbed, by treatment with chromic acid.

4. Cheese-cloth, sold cheaply by all dry goods dealers, saturated in the standard solution, and used for compresses and bandages.

5. Absorbent cotton, saturated in the standard solution and dried. There are many good makes.

6. An ounce or more of iodoform in an ordinary pepper box, for dusting, or as I use and prefer, one of the cheap insect-powder guns, sold in all drug stores.

Armed with the six articles I have just named, and which can all be carried in small compass in the ordinary bag, I am prepared to state from experience that for all ordinary uses in private practice the antiseptic principle can be successfully carried out, the entire practice, after all, being surgical cleanliness. Carbolic acid solutions are never absolutely required. Cutting instruments cannot, it is true, be immersed in the bichloride solution, but they can be effectually sterilized by immersion in boiling water, and the same is true of the needles used. I have omitted mention of the "protective" used by many, and though I have never observed irritation from its use, I do not use it, but it can be secured for a trifle, if desired. Capillary drainage is sufficient for nearly all wounds dressed antiseptically, and where tube drainage is desirable the tubes are easily sterilized.

—“To what do you attribute the curative properties of your springs?” asked a visitor at a health resort. “Well,” answered the proprietor thoughtfully, “I guess the advertising I’ve done has had something to do with it.”

² A one to three thousand is better; one to one thousand is too strong.

URETHRAL FISTULA; RELIEVED BY EXTERNAL PERINEAL URE- THROTOMY.

J. W. HUFFMAN, ROANOKE, ILL.

In the REPORTER, August 6, 1887, is an article on an injury of the perineum and urethra, the character and features of which are somewhat like a case which occurred in my practice four years ago.

On September 5, 1883, I was called to see Wm. G., aged 13 years, who had been thrown from a horse the evening before, and had been struck on the perineum by the hoof of the animal. The parts in and around the perineal region were considerably bruised, and presented a blackened appearance, but with the exception of a slight cut on the scrotum, the skin was unbroken. The boy was unable, and he had been so from the time of injury, to pass his water, but a catheter was introduced without much difficulty, and a quart of bloody urine drawn off, after which he was enabled to empty his bladder at will.

On the 8th of September, four days after the reception of the injury, I was called to see him again, and found, about an inch from the margin of the anus, a fistulous opening in the median line of the perineum, through which he then voided his urine. After the bladder had been emptied at the time of my first visit, the boy had experienced no further trouble in that line until the evening of the 7th, when he found that a *portion* of the urine “trickled down his legs,” and did not pass out through his penis. He thought it came from his anus, and his description was, that at first only a few drops passed through this unnatural channel, but at each succeeding urination the quantity passing through the fistula was increased, while the amount coming through the penis was correspondingly diminished until noon of the 8th, when all the urine passed through the perineal opening.

I endeavored to pass a catheter but failed, and notwithstanding the fact that various shapes and sizes of instruments were used they could be passed only up to a certain point which was near to the lower portion of the spongy part of the urethra. On the 15th, with the assistance of Dr. A. H. Kinnear, of Metamora, Ill., now of Henry, Ill., the boy was chloroformed and an attempt made again to pass a catheter into the bladder; but we failed as before, and were convinced that the urethra was permanently closed at the point above designated, and that an operation

would have to be performed to overcome the difficulty. To this the parents objected, hoping that time, that great doctor, would set matters right; but after waiting until Oct. 8th, one month after the date of the injury, they concluded that an operation was the only means of relief. Accordingly, at that date Dr. Kinnear and I performed the operation of external perineal urethrotomy. A staff was first passed into the urethra as far as the stricture and an incision made in the median line of the perineum as deep as the end of the staff, the external cut being an inch and a half long. Examination then showed that for more than an inch the urethra was completely closed, resembling a hard tense cord in feeling. An opening was made into the urethra at the external end of the stricture and the staff was withdrawn and a silver catheter passed in its stead, the catheter passing out of the urethra through the opening just mentioned, and around or external to the stricture. Some little difficulty was experienced in finding the inner opening into the urethra, through which the water escaped from the bladder, and which seemed to be about an inch and a half from the other end of the stricture, and directly under the arch of the pubic-bone, in the membranous portion. However, after some manipulation, the catheter entered the bladder and was allowed to remain four days, when it was withdrawn and a soft rubber catheter introduced instead, which was left there until the parts were nearly healed. No attempt was made to divide or lay open the stricture, the catheter passing entirely outside the urethra for more than an inch.

The external wound healed kindly, and perfect success followed the operation.

A singular feature in the case was the ability to pass urine for 72 hours before there was any discharge through the fistulous opening, while at the same time there was no infiltration of urine in any of the adjacent structures. *An interesting question relates to the growth of the new urethra around the catheter, that instrument being, as already stated, completely external to the urethra for more than an inch of its length.*

—At the meeting of the British Medical Association at Dublin, Dr. Thomas Bridgewater, of Harrow, was elected president of the council for the next three years. An invitation to visit Glasgow next year was accepted; and Professor W. T. Gairdner was appointed president-elect.—*Am. Ed.*

LIGATION OF THE THIRD PART OF THE RIGHT SUBCLAVIAN ARTERY EXTERNAL TO THE SCALENI MUSCLES, FOR ANEURISM: DEATH ON THE SEVENTEENTH DAY FROM ABSCESS OF THE SAC AND SEPTICÆMIA.

BY H. H. CLARK, M. D.,

Surgeon to St. Francis Hospital, etc., etc., Pittsburgh, Penna.

John Charlton, an Englishman, aged 65 years, laborer, was admitted to the surgical ward of St. Francis Hospital on May 29th, 1887, suffering from aneurism of the third part of the right subclavian artery. He was a man of small size, slender and of dark complexion; had never had syphilis, and lived a fairly temperate life.

About three years ago he called at my office to consult me in reference to a constant aching pain which he complained of, and which he located in the region of the right clavicle, extending down the entire arm. The pain was considerably aggravated upon any undue exertion, such as rapid walking, etc. I prescribed quinia and belladonna, thinking probably that he had an attack of neuralgia, and told him to come back in a week if he was not relieved. He returned at the appointed time, saying that "the medicine had done no good." I requested him to strip off his coat and shirt, and proceeded to make a more careful examination. I now discovered a well-defined globular tumor just above and near the centre of the clavicle about the size of a walnut. By firmly pressing upon it, a distinct thrill could easily be detected, removing all doubt as to the true character of the disease, viz., aneurism.

Having informed my patient of the dangerous nature of his malady, I advised him to take to bed for six weeks and undergo Tuffnell's treatment, which is so well known to the profession that a description is unnecessary. He would not consent to the treatment, however, and I lost sight of him for over two years.

In November, 1886, he again made his appearance at my office, earnestly entreating me to do something to relieve his suffering, which had now become unbearable. The tumor had increased considerably since I last saw it, so that it was now about the size of a hen's egg, while the clavicle was also raised higher than its fellow. Being a poor man I advised him to enter the Western Pennsylvania Hospital, where he would receive medical and surgical treat-

ment free. He took my advice and entered said hospital, placing himself under the care of an eminent surgeon of that institution. He remained in the hospital fifty-two days, undergoing Dr. Tufnell's treatment, but without any benefit. Ligation of the artery was next proposed, but he would not consent to an operation, and left the hospital.

Four months having elapsed, he sent for me one day in great haste, and requested that I perform the operation at once, as he could bear the pain no longer. I consented and gave him a permit of admission to St. Francis Hospital.

Accordingly on June 2d, 1887, the patient was etherized and brought into the operating room before many eminent physicians, and placed in the usual position recommended for the operation. I commenced by drawing the skin down over the clavicle and making an incision about four inches long over the upper surface of that bone, dividing the integument, superficial fascia and platysma muscle. Continuing the dissection by means of the fingers and a director through the adipose and connective tissue, the outer edge of the scalenus anticus muscle was brought into view. After a little further dissection (in which Dr. Joseph Dixon assisted), which was rendered tedious and difficult by the displacement of the clavicle and alteration of the surrounding parts, we succeeded in finding the artery deeply situated in the neck. We then, before tying it, tested the effect of pressing the vessel against the first rib, and finding that all movement had ceased in the aneurism and radial pulse, we insinuated a plain aneurism needle previously threaded with ordinary silk under the artery; then withdrawing the needles tied the silk to the end of a chromatized catgut ligature, drawing it through under the artery, which we securely tied. The catgut was obtained at a music store and is called "Cello violin string D." The wound was closed with silk sutures and two pieces of the same catgut introduced into each end of the wound to secure drainage. An antiseptic dressing was applied and the whole secured with a bandage. The shoulder and arm were wrapped in cotton and hot bottles applied to secure warmth and prevent mortification.

2d day.—I visited the patient with Dr. Stewart, the house surgeon, and found him free from pain for the first time in two years; the pulse was 96, temperature 100°. Ordered 2 grs. of quinine three times a day, and morphia if necessary. The arm continued warm and pulseless.

4th day.—Pulse 104; temperature 101 $\frac{3}{4}$ °. Removed drainage tubes and directed the daily washing of the wound with bichloride water, and iodoform applied externally.

8th day.—Removed all sutures, and found a slough of both edges of the wound about the size of a quarter dollar. Pulse 104; temperature 102°; patient weaker; continued quinine in larger doses (4 grs.), and added stimulants with a nutritious diet.

12th day.—Found the patient growing weaker and drowsy; wound suppurating freely; pulse 108; temperature 102°.

13th day.—Pulse 108; temperature 102°. Diarrhoea now set in and two bed sores were discovered over the sacrum.

15th day.—Pulse 112; temperature 102 $\frac{1}{4}$ °; diarrhoea still continued; patient delirious and bed sores spreading.

16th day.—Pulse 140; temperature, 104°; patient sinking.

17th day.—Patient died at 4 o'clock, A. M.

Post mortem examination made five hours after death in the presence of friends, and Dr. Stewart, house surgeon.

Upon removing the clavicle, the sack, together with the surrounding parts, was found full of pus; the sack was probably ruptured whilst making the post mortem examination. The ligature was found encircling the artery effectually, but not changed in the least; this I noted particularly, for I had expected to find the ligature partially absorbed. The artery was brittle and readily torn asunder, which I attributed to its atheromatous condition.

Death was caused by septicæmia, superinduced by abscess of the sac.

VOMITING OF PREGNANCY.

BY J. E. FREE, M. D., BENEZETTE, PA.

Sometimes the most troublesome, obstinate, and least dangerous condition, which the physician is called upon to treat, is the gastric derangement peculiar to pregnancy. It was once my custom to run the gamut of remedies for sick stomach in a particularly difficult case, and if relief was not obtained, to treat the patient upon the expectant plan; the most masterly inactivity usually triumphs in the end; and although the patient may have been at the limit of her good nature, when labor is accomplished suffering is forgotten.

There are a number of specifics for the vomiting of pregnancy, but they have all

failed me in turn. When attention is directed to the intestinal function as well as to that of the stomach, the results of treatment improve. It is rational to suppose that so powerful a factor in a woman's life as conception should influence the whole, instead of only a part, of the alimentary canal.

Frequently constipation is the warning nature gives of a disturbance of the abdominal equilibrium. It was not always habitual, as at present, to regard the condition of the bowels; indeed it is possible to recall cases where prescriptions have been given, and nothing been known as to their action. When questioned upon this subject, a woman suffering from the exasperating sickness of child-bearing does not always supply reliable data upon which to base treatment.

Where there is any uncertainty in this particular, I usually prescribe calomel and ipecac, with perhaps gamboge enough to thoroughly evacuate the intestines, and if it be necessary, an enema is given daily to sustain the effect.

The following prescription has done good service after the bowels have been attended to:

R Sodii bicarb..... ʒ ij
 Acid. hydrocyanic, dil..... ʒ xxxij
 Syrup of lactopeptine..... q. s. f ʒ iv
 M. S.—f ʒ half hour before meals.

Orange juice is also a favorite remedy. In the winter of 1886 a patient who could tolerate nothing in the shape of food or medicine suddenly developed a taste for oranges. The appetite followed the taking of a teaspoonful of oil of rue. Instead of causing an abortion, and thus relieving the woman's suffering, it set up a sharp gastro-enteritis, which eventuated as stated. The effect of the fresh juice taken *ad libitum* was that of a laxative, and a most distressing case, which had taxed the skill and ingenuity of two physicians, was relieved as if by magic.

Recently a case of a different description has been under observation. The patient was thirty years old; she had the finest set of teeth I have ever seen in any person of her age, in spite of the fact that four years previously she was the victim of acute pytalism, which made them loose.

For six months the patient had gastric irritability. At the end of this period there was an amelioration of this symptom, and by what seemed to be a metastasis, a sore mouth developed, which gradually assumed the character of a phagedenic ulcer. Her medical attendant at this time used local treatment entirely.

When she came under my care she was eight months gone in pregnancy. Her mouth was as filthy and stinking a thing as it is possible to imagine. The entire roof was involved, and pus was constantly dribbling from the lips. If she happened to turn on her back at night, the secretion from this surface would get into the stomach and cause violent attacks of retching and vomiting when she waked up. Her complexion was decidedly bilious, and she had not had a movement of the bowels for a week.

She was at once placed upon calomel and ipecac, although the history of former salivation made me hesitate for some time before giving it to her. Over the external surface of the nose there was an erysipelatous swelling which remained stationary, while the mouth healed up very kindly. While waiting to see what the sore on the nose was going to do, confinement occurred, and in spite of the prophecy of several wiseacres in the neighborhood, the child was a healthy male, weighing seven pounds, and did not have cancer of the mouth, or anything else abnormal.

It was my opinion that *tr. ferri chloridi* would cause the patch of erysipelas on the nose to disappear, but having been accused once of nearly killing a woman by the administration of iron and ergot in the second week of the puerperal state, I hesitated about giving it, just as with the mercurial. Finally, however, I banished my fears and gave the following:

R Potass. nitrat.....
 Potass. chlorat... āā ʒ j¹
 Antimonii et potass. tart..... gr j
 Tr. ferri chlor..... f ʒ iv
 M. S.—f ʒ every four hours.

The improvement in the patient's condition was most satisfactory. And instead of a tedious getting up, the woman went about the house after the tenth day, and while before she was a quasi-invalid for several months she is now enjoying most perfect health.

If the improvement in this woman's condition had been postponed for a short time after taking the medicines prescribed, there would have been strong grounds for the supposition that it was nature which had accomplished the cure; but under the circumstances the treatment comes in for its share of the praise.

¹ This dose of chlorate of potash seems large.—
 [EDS. REP.]

SOCIETY REPORTS.

NINTH INTERNATIONAL MEDICAL CONGRESS.—WASHINGTON, 1887.

WEDNESDAY, SEPTEMBER 7.—GENERAL SESSION.

The address before the general meeting was delivered by Dr. Mariano Semmola, of Naples, Italy. Dr. Davis resigned the chair to Dr. Durante, the official representative of Italy at the Congress. The subject of Dr. Semmola's paper was

Bacteriology in its Therapeutic Relations.

After a few introductory remarks, the speaker affirmed that the primary object of medicine was to cure disease. The true test of medical progress is the answer to the question, Are many or few saved from death? Typical health and happiness are expressed in the old adage "*mens sana in corpore sano*." But true medical progress is necessarily slow, and many false paths and many winding mazes have been followed from Hippocrates to the present time. Close and careful observation, combined with the experimental method of research, are the true ways of advancing medical knowledge. The aim of medicine is the aim of all branches of knowledge, precision. The experimental method is made up of three parts—observation, hypothesis, proof. Hasty hypotheses only retard progress. Scientific medicine concerns itself not with the causes of existence, but with its conditions, phenomena, manifestations. The physician should not aim to command nature, but to obediently follow her. The great scientists, Franklin, Stephenson, Daguerre, Edison, in becoming servants of nature, have learned how to use her powers.

Taking up the subject of Bacteriology, the Professor said that the first light was thrown upon it by Cagniard Latour in 1825. The investigations of Colin and Davaine in 1851, and by Pasteur in 1861, were productive of real progress. Rüdinger also demonstrated the limitations of growth of moulds. But withal, the bacteriology of the present day does not show the true experimental method of research. Many of the diseases in which bacteria are found are not caused by bacteria. If a phthisical patient were freed from bacilli, he would still die of phthisis. And while the discoveries of Lister have enabled us to shut out poisonous materials that would otherwise enter the body, we still cannot

use Lister's success as an argument for the employment of parasitocides. Nor can we proceed from the destruction of germs out of the body to argue that the internal administration of antiseptics would meet with success. Moreover, a later school of experimenters, to which belong Nencki, Husemann, Gussenbauer, Kobert, Brieger, Georgi and others, have refuted the reasonings of the purely bacteriological experimenters. The sum of the whole thing is to preserve our health, and save our strength, and as a result, disease will be least apt to affect us.

After referring to the falsity of the modern practice of giving drugs to destroy germs within the body, the Professor closed with an exhortation to adopt correct principles of close observation, and to follow science in a true, catholic spirit.

Section in Therapeutics.

Dr. John E. Brackett, of Washington, D. C., read a paper on "Rhamnus Purshianus," which consisted of a botanical and chemical description of *Cascara Sagrada*. He gave the fluid extract twice daily in doses of five to fifteen drops, and thought it was curative in chronic constipation.

In the discussion which followed, Dr. Murrell differed from Dr. Brackett, while Dr. Phillips coincided with the author as regards the therapeutic value of the drug.

Dr. Ralph Stockman, of Edinburgh, read the next paper, upon "The Pharmacology of Some Bodies Derived from Morphine." The paper was a record of chemical experiments, still uncompleted, conducted by the author and Dr. D. B. Dott.

Dr. A. L. A. Toboldt, of Philadelphia, read a paper on "Carlsbad Mineral Waters."

He was followed by Dr. Geo. S. Hull, of Chambersburg, Pa., who read a paper on "The So-called Antiseptic Action of Calomel when Given in Large Doses." The author detailed successful results obtained from the use of calomel in large doses in epidemic dysentery.

Section in Anatomy.

The first paper was read by Dr. Jos. N. Dixon, upon "Anatomical Considerations in Regard to the Amputation and Disarticulation at the Ankle Joint by a New Method."

This consisted in making an incision in front of the line laid down by Syme, around the sole of the foot from malleolus to malleolus, and also an incision a little above the plane of the articular face of the tibia. The advantages claimed are a long plantar flap, shortening of the superior section, division of the malleoli obliquely, and preservation

of the bursa between the tendo Achillis and the head of the os calcis.

Of fifty-two cases operated on in this way there had been three deaths, one or two of which had had other injuries. The average stay in hospital was twenty-one days. The age of the patients varied between four and sixty-five years.

At the Afternoon Session, Dr. H. C. Boenning, of Philadelphia, read a paper on "Destruction of the Offal of the Dissecting Room," in which he recommended as the most serviceable method the use of the Gregory furnace.

Section in Ophthalmology.

The first paper presented was by Dr. C. F. Hotz, of Chicago, Ill., on "Restoring the Normal Position of the Free Tarsal Border in Trichiasis."

Dr. B. Pitts, of St. Joseph, Mo., followed with a paper on "The Best Method of Operating for Entropion," in which he spoke of the advantages of electrolysis.

The next paper was by E. Landolt, of Paris, France. The subject of the paper was "Operation for Strabismus." Before operating, find out what the refraction and accommodation are. Obtain everything possible by non-surgical measures first. It is better to do too much in the way of cutting than too little. If divergence persist, the cut muscle can be advanced as late as the tenth or twelfth day.

At the Afternoon Session, Dr. Geo. F. Stevens read the first paper, on "Some Important Problems Respecting Insufficiency of the Ocular Muscles." The purpose of the paper was to suggest certain problems, rather than to explain their apparent contradictions.

Dr. J. F. Fulton, of St. Paul, Minn., followed with a paper on "Advantages of Early Operation in Strabismus."

Subsequently, papers were read by Dr. C. H. Abadie, of Paris, France, on "Faulty Eye movements, and the Means of Remedying Them;" by Dr. E. O. Shakespeare, of Philadelphia, on "The Strength of the Superior Recti Muscles as a Cause of Asthenopia;" and by A. G. Heyl, of Philadelphia, on "Abnormalities of the Visual Axis."

Section in Dermatology.

The first paper presented was by Dr. A. Ravogli, of Cincinnati, on "Lupus Erythematosus," in which the author stated that there was a true atrophy of the skin affecting all the layers, and that the cause of this was occlusion of the blood vessels and obliteration

of them by pressure. He had found round bodies in the enormously enlarged epidermic scales, which he regarded as micrococci. These micrococci he considered causative.

Dr. Unna disputed the correctness of regarding these bodies as micrococci, though the presence of such parasites would no doubt be demonstrated some day.

The next paper was read by Dr. Ohmann Dumesnil, of St. Louis, Mo., on "Erythematous Lupus of the Hands," of which the author reported 45 cases. His treatment was lactic acid in the form of a paste.

"Contribution to the Knowledge of Impetigo Herpetiformis" was the title of a paper by Dr. Josef Zeisler, of Chicago, Ill.

Section in General Medicine.

The three papers presented before this section, were: "The Study of the Natural History of Disease," by J. A. Ouchterlony, M. D., of Louisville, Ky.; "Inebriety and its Treatment," by Dr. T. D. Crothers, Hartford, Ct.; and "Typhoid Fever," by Dr. Cisna, of Pennsylvania.

Section in Climatology.

The first paper presented was by Dr. A. Tucker Wise, of Engadine, upon "The Climate of the Swiss Alps, with Pulmonary Cases Treated at an Altitude of Six Thousand Feet." His paper reported twenty-three cases that had been improved by a residence of from one to sixteen months. This the author attributed to the pure dry air.

Dr. J. D. MacDonald, Inspector General of the Royal Navy, read the next paper on "Ground Air in its Hygienic Relations."

He was followed by Dr. P. H. Boyce, of Toronto, Canada, Secretary of the Provincial Board of Health. In his paper, which was entitled "House Atmospheres, or Artificial Climates," the author recommended good hygienic dwellings with plenty of sunlight.

Section in Dental and Oral Surgery.

The opening paper was presented by Dr. Pradère, of Lyons, France, upon "Phthisis Cured by the Continuous Application of Medicine to the Palate."

Dr. James Truman, of Philadelphia, moved that the paper be not accepted by the section, but be referred, without discussion, to Section I. in General Medicine. The motion was carried against the ruling of the chair that the paper should be accepted inasmuch as the Executive Committee had seen fit to admit it.

A number of highly successful clinics were then given; following these, a paper was

read by Dr. Metnitz, of Vienna, Austria, on "Osteomyelitis," in which the author reported two very interesting cases.

Dr. Jenison, of Minneapolis, then read a paper on "Art in Dentistry," in which the author advocated the restoration in gold of all teeth that had been destroyed by caries.

At the afternoon session, the following papers were read: "The Origin of the Dental Fibril, Illustrated by Aid of the Stereopticon," by R. R. Andrews, of Cambridge, Mass.; "Protective Dentine, Illustrated by Stereopticon," by Dr. Fletcher, of Cincinnati, Ohio; and "Photo-micrographs of all the Structures of the Tooth," by Dr. J. Howard Mummery, London, England.

Section in Gynecology.

Dr. Ernest W. Cushing, of Boston, Mass., read the first paper on "Cancerous Degeneration of the Hyperplastic Glands of the Cervix Uteri." The author felt obliged to differ from the statements of Ruge and Veit. He regarded even a series of adjacent glands whose lumina were filled with epithelium as adenomas. It does not become carcinoma until epithelial infiltration occurs in the connective tissue between the glands. Nevertheless the growth should be removed.

Dr. F. H. Martin, of Chicago, Ill., followed with a paper on "A Method of Treatment of Fibroid Tumors of the Uterus by Stronger Currents of Electricity based upon Exact Dosage." The writer praised the practice of Apostoli, of Paris. Dr. Martin has an original method of calculating dosage, experiments being cited which showed that a certain local effect may be expected at an active electrode of given surface from a definite strength of current passing for a certain length of time.

Dr. Thomas More Madden, of Dublin, read a paper on "Some Points in the Pathology and Treatment of Lacerations of the Cervix Uteri." The author desired to direct attention to lacerations of the cervix as the cause of one of the most troublesome forms of post-partum hemorrhage; and to the occasional occurrence of septicæmia as the direct result of lacerations of the cervix uteri.

Dr. Leonard Meyer, of Copenhagen, Denmark, then read a paper entitled "Contributions to the Pathology of Inflammation of the Lining Membrane of the Uterus."

Dr. Alfred C. Garrett followed with a paper on "Tumors of the Breast Treated by Electrolysis." His statistics show that out of 186 tumors treated since 1864, 157 disappeared and have not returned.

Dr. W. H. Weeks, of Portland, Me., read a paper on "Myoma in Pregnancy," in which he had been induced against his better judgment to bring on premature labor. His own wish had been to await labor, and if it were impossible for the child to be born, to at once perform Cæsarean section by Sanger's method.

Dr. Alexander Dunlap, of Springfield, Ohio, followed with a paper on the "Early History of Ovariectomy in America."

The next paper was read by Professor A. Cordes, of Geneva, Switzerland, on "Medical Topical Treatment of Uterine Cancer."

This was succeeded by a paper on "A New Theory and Treatment of Displacements of the Uterus by Electricity," by Dr. A. Laphorn Smith, of Montreal; and one on "Some New Applications of the Induced or Faradic Current to Gynecology," by Apostoli, of Paris.

Section in Diseases of Children.

The first paper was presented by Dr. Cyrus Edson, on "The Milk Supply of Cities." The speaker urged that herds of cattle should be inspected at intervals in order to secure the destruction of animals suffering from tuberculosis.

Following this came a paper by Dr. Paul Redard, of Paris, on "The Treatment of Erectile Tumors by Electrolysis," for which treatment he claimed successful results in his own dispensary practice.

Dr. De Valcourt, of Paris, followed with a paper on "Sea-bathing as a Treatment of Tuberculosis."

At the Afternoon Session, Dr. Isaac N. Love, of St. Louis, Mo., read a paper on "Infantile Marasmus." He regarded a certain class of cases as not due to tuberculosis nor to syphilis or intestinal catarrh, but to inactivity of the glandular system, due in part to bad hygiene and in part to indiscretions in diet. The most important part of treatment is to arouse the secretions, for which purpose calomel in doses of $\frac{1}{10}$ grain is best. The mother's milk is the best food. In extreme cases, nutritive baths coupled with massage are recommended.

Dr. Wm. H. Day, of London, followed with a paper on "Some Observations on Headaches in Children and Their Relation to Mental Training." These headaches are due to mental overwork, and are not infrequently accompanied by refractive troubles of the eye.

The next paper was by Dr. Wm. D. Booker, of Baltimore, on "A Study of Some

of the Bacteria Found in the Dejecta of Infants Affected with Summer Diarrhoea." The author had found twelve different kinds of bacteria, eleven of which were bacilli. Their effects upon animals, as determined by post-mortem examination, were detailed.

Section on Military and Naval Surgery and Medicine.

Prof. Frederic Hyde, of Syracuse, N. Y., read the first paper, on "The Proper Treatment of Penetrating Wounds of the Joints."

The author recommended antiseptic treatment, but, in case suppuration occurs, free opening of the joint. Immobility must be secured by a plaster of Paris dressing.

A paper upon the same subject was read by Dr. Geo. L. Porter, of Bridgeport, Ct., which had especial reference to injuries of the knee joint.

At the Afternoon Session, the first paper presented was by Dr. W. S. Tremaine, U. S. A., upon the question, "Is Laparotomy for Gun-shot Wounds of the Intestines Feasible in Military Practice, and its Technique?" Also one upon "The Treatment of Penetrating Wounds of the Abdomen."

A paper upon "The Proper Treatment of Penetrating Wounds of the Abdomen" was read, in the absence of the author, Dr. S. T. Armstrong, U. S. A., by Dr. Smith, of the army.

The final paper presented was by Dr. Henry James, of Waterbury, Vt., upon "Non-fatal Penetrating Gun-shot Wounds of the Abdomen Treated Without Laparotomy." The author thought, as the result of his own experience in twenty-seven cases, that laparotomy was sometime performed when it was not necessary.

Section in Laryngology.

Dr. H. H. Curtis had the first paper, upon "Surgery of the Nasal Septum and Turbinate Bones."

This was followed by a paper on "Primary Erysipelas of the Larynx," sent by Dr. Massei, of Naples, Italy. It was generally agreed in the discussion that such disease exists, and some held that it is not so very uncommon.

Another paper, on "Twenty Years of Laryngological Work in the City of Mexico," was sent by Dr. F. Semeleder, of Mexico.

The final paper was presented by Dr. F. B. Eaton, of Portland, Me., on "The Present Status of the Galvano-cautery in the Treatment of the Diseases of the Upper

Air-passages, Illustrated by Instruments and the Description of Cases." This author also being absent, the paper was read and the instruments were exhibited. The author recommended his instruments in preference to all others.

Section in Obstetrics.

Prof. Alexander Simpson, of Edinburgh, in opening the discussion in Cæsarean Section, said that he did not yet think we could set aside craniotomy for Cæsarean section. The latter, when performed, should be done by Säger's method. When the uterus is diseased, he would employ Porro's method.

Professor August Martin, of Berlin, Germany, thought the Säger operation a safe one, but also thought that it is now performed when version could be done.

At the Afternoon Session, a paper was read by Dr. J. A. Doléris, of Paris, France, on "Treatment and Surgical Restoration of the Cervix During Pregnancy." The author had operated with successful results in several cases. He advised the operation where there was danger of abortion without it.

Dr. Joseph Kücher, of New York City, followed with a paper on "The Relation of the Atmosphere to Puerperal Fever," which was an urgent plea for pure air in the lying-in chamber.

Dr. Thos. More Madden, of Dublin, presented a paper on "The Prevention and Treatment of Puerperal Septicæmia."

The following papers were also read: "A Study of Certain Questions in Connection with Puerperal Fever, with Particular Reference to the Use of the Intra-uterine Douche and Curette," by Dr. Ch. W. Earle, of Chicago, Ill.; "The Prevention of Puerperal Fever," by Dr. R. Lowrey Sibbet, of Carlisle, Pa.

Section in Surgery.

As the paper of Dr. Maclean, read the preceding day, was fully discussed at this meeting, we will present an abstract of it here, so that the paper and discussion may be read together. The title of his paper was "Three Cases of Laparo-Nephrotomy."

Case I.—Mrs. A., aged 25 years, presented herself with what had been diagnosed as an ovarian tumor. There was a cystic abdominal tumor about the size of the uterus at the seventh or eighth month of pregnancy. There was no history of renal trouble and no evidence that the tumor was connected with the kidney. The patient insisted that it had begun to grow from below. The operation was done with the expectation of removing

an ovarian tumor. The left ovary was found enlarged to the size of a goose-egg, and was removed. The large tumor was found to arise from the kidney, and it also was removed. The patient did well for a time, though suppuration, with the formation of an intestinal fistula, occurred; nevertheless she finally made a perfect recovery.

Case II.—Mrs. T., aged 40 years, presented herself with a tumor of the left side of the abdomen, which had been discovered six years previously. The enlargement had gradually increased. The tumor when first seen was too high for the ovary and too low for the spleen. The urine was normal. A diagnosis of tumor of the left kidney was made. It was decided to adopt the trans-peritoneal method of operating. A large cyst of the kidney was found. During removal it ruptured with the escape of a material like soft soap. The posterior layer of the peritoneum was brought together with sutures. The case did well until the eleventh day, when the temperature went up until it reached 104°. Examination showed fluctuation in the lumbar region. An opening was made, with the escape of a large quantity of pus. Symptoms of collapse followed this operation, but these were overcome, and the patient made a gradual recovery.

Case III.—A female infant, 22 months old. The family history was good. There was a tumor in the right hypochondriac region. This was moveable and free from tenderness and pain. Tumor of the kidney was diagnosed and removal recommended. The incision was made just external to the rectus muscle. No difficulty was experienced, and the operation was completed in seven minutes. The posterior layer of the peritoneum was closed with cat-gut sutures. For several days the case progressed favorably, but the temperature remained high. On the fifth day a careful examination was made to determine the cause of the elevated temperature. During the examination the child coughed and the abdominal incision gave way, allowing the intestines to escape. These were replaced, and a search failed to show the source of the trouble. The wound was reunited, but the temperature continued high, and the child died on the ninth day. At the autopsy the posterior layer of peritoneum was found united and in the space occupied by the tumor a small collection of pus was found surrounding the ligature on the pedicle of the tumor.

The speaker said that while the lumbar operation might be the safer there were cases in which the trans-peritoneal operation was

preferable. These cases point to the necessity of securing efficient drainage, even though antiseptic precautions are adopted.

The discussion upon Dr. Maclean's paper was opened by Dr. Herff, of San Antonio, Texas, who said:

"I quite agree with Dr. Maclean that in suitable cases laparo-nephrotomy is the proper operation. Some years ago I had a patient, a young woman who was newly married, and when about two months pregnant she discovered a tumor on the right side, nearly as large as a child's head. She had no pain, and except that she had this tumor, she was in good health. The tumor, however, annoyed her very much, and she insisted on an operation being done. I therefore opened the abdomen in the median line and removed the tumor. The remarkable thing about the case was that the tumor which I had thought an ovarian one, proved to be the kidney and supra-renal capsule. From the lower end of the tumor, the lower part of the kidney was hanging, while the upper part consisted of the supra-renal capsule enormously enlarged, sections of which presented under the microscope the appearance of the long cells of myoma. The patient made a good recovery, and two years after the performance of the operation she was in perfect health. This, while a case of removal of the kidney, was also a removal of the supra-renal capsule, which made the case more remarkable to me, because I have never read of its removal for disease.

Dr. Dawson said: With reference to these cases I wish only to thank Dr. Maclean for his kindness in bringing them before the section. It is very interesting to look back a few years and see the advance in suagery that has taken place.

Dr. Hughes said: I have had precisely the same number of cases of kidney disease as Dr. Maclean, and I perfectly agree with him in everything save one, and that is the seat of operation. He seems to prefer the abdominal incision, while in all cases where it is practicable, I would give the preference to the side, between the ribs and crest of the ilium. My first case I operated on by means of the abdominal incision, the only way that I could do, as the tumor was so large a one that it could not have been brought through the opening between the ribs and the crest of the ilium. The second case was only a tumor about the size of the fist, and I operated in the space between the ribs and anterior crest of the ilium. I also operated on the third case by incising the lumbar region,

and from these last cases I got the best results, and also avoided opening the peritoneum.

Dr. Edmund Owen, of London, remarked: There are at least three factors which must influence the choice of the operation in each case: first, if there were doubts as to the exact nature of the tumor the anterior operation would be chosen, and second, if the tumor were very large, the anterior incision must be chosen. Lastly, there was the line of practice of the individual surgeon; the gynecological operator would naturally prefer the trans-peritoneal incision, even for a small tumor, because that is to a certain extent his own province, while the general surgeon would choose the space between the last rib and the crest of the ilium, because for some reason, rather undefined, he does not care to touch the peritoneum if he can avoid it. In a case of diseased kidney, which I removed successfully, I made the incision through the linea semilunaris.

Dr. Harden remarked: I had a case somewhat similar to one which has been related here. In my case I made the anterior section; but did not remove the tumor, on account of an enormous flow of blood, which would have become so alarming if we had attempted to separate the tumor from its connection, that I feared the patient would die; so all further operation was stopped. The tumor was shown after the death of the patient to be a kind of fibro-cystic tumor of the kidney.

Dr. Lange, of New York, said: In a large number of cases of tumor of the kidney where there exists fluctuation, we have to do with pyonephrosis of usually very large size. I have operated several times for the removal of the kidney, and performed both the anterior and posterior operations. In the small tumors and in some of the larger ones, I prefer to make a small lumbar incision, empty the contents of the tumor out as far as possible, and then wait until the remainder of the tumor lessens in size, which it will be very apt to do, so that it can be extracted through even a very small hole or incision. Sometimes in renal calculi I have performed laparotomy, or rather the operation in the lumbar region, and then, after making this incision, on placing these patients in bed lying on their stomachs on a pillow the kidney would float up when the wound was made, and could then be easily removed and the calculus extracted.

Dr. Maclean, in closing the discussion, said: There were very good reasons in each of the cases why I should choose the anterior

operation; they were all too large for the lumbar incision.

Tumor of the Head, Probably Intra-cranial.

A patient with a tumor of the head was presented to the section, and was referred to a committee for examination. The committee consisted of Drs. Moore, Dawson and Brosseau. This committee reported that there was a large tumor of the head, five inches in diameter, occupying the temporo-parietal region, occurring in a man 35 years of age, and of twenty months duration. There was some headache; some blindness, greater on the right side; and deafness on the left side. The tumor was raised one inch above the surface. The committee believed that the growth was intra-cranial, causing expansion and partial absorption of the bones, while operation would hardly be successful. Still, as the case must progress to a fatal termination, it would be proper to remove a portion of the skull, and if the growth was outside of the dura matter, there would be a reasonable prospect of success.

Dr. M. H. Richardson, of Boston, next read a paper entitled "Gastrotomy for Foreign Bodies in the Œsophagus," in which he said that this operation was intended only for the removal of foreign bodies in the Œsophagus, which had passed so far down as to be lodged near the cardiac orifice of the stomach. In regard to the length of the incision, it was not fixed; it might be only a very short one, or it might be made large enough to put the hand inside the stomach so as to reach up into the Œsophagus, if that should be necessary, in order to extract the foreign body. The incision through the skin should be made over the cardiac end of the stomach, or might be made in the median line, but the incision through the walls of the stomach must be made at the cardiac end of the stomach. All the caution necessary in making this was to get the incision made without wounding the convexity of the lesser curvature of the stomach. In order to avoid this the better way was to put the lesser curvature on the stretch. After the opening into the stomach was made, instruments might be introduced for the dislodgement of the foreign body, or if they were insufficient the fingers and hand might be passed in, which would enable one to relieve the Œsophagus of its burden. As to the scope of the operation, while it was chiefly applicable to the removal of foreign bodies, it might be useful in other ways, as its capabilities were considerable, as had been demonstrated by his experiments

on the cadaver. He concluded that if the foreign body was lodged within six inches of the lower edge of the cricoid cartilage, it was best removed by an operation from the side or above, but if situated more than six inches from the cricoid cartilage, gastrotomy was the best thing to be done. He then exhibited a patient from whom he had removed a plate of false teeth by means of gastrotomy.

Dr. F. S. Denis, of New York City, then read a paper, the title of which was "Report of an Amputation at the Hip Joint for the Removal of a Sarcoma," in which he said that it was only by collecting the cases which occur from time to time and comparing them that we are able to advance our knowledge. This case was that of a young man, aged 17 years, who had no bad family history, and who had always been in good health until about five months prior to his admission to the hospital. At the time of his admission his weight was eighty-five pounds. Five months prior to his admission he had first noticed a dull pain in the thigh, and shortly afterwards he discovered a swelling in the thigh. He had had no fall or blow. About two months after the first appearance of the pain, the tumor was aspirated, and about two ounces of bloody fluid drawn off. The swelling was fusiform in shape, the skin purple, with large veins running over its surface, while the glands of the thigh and groin were much enlarged. The diagnosis was sarcoma of the femur, and amputation at the hip joint was suggested as the only means of saving life. This amputation was done, and the wound dressed antiseptically. The wound was entirely healed by the sixth or eighth day after the operation. After the patient left the hospital the wound re-opened a little, and discharged pus mixed with blood; this was found to be due to sloughing of the ligamentum teres, upon the removal of which the wound healed kindly, and the young man is now well.

Dr. Jasper J. Garmany then read a paper on "The Surgical Treatment of Epilepsy by Trephining," in which he related the case of a girl, about eighteen years of age, who had been struck on the head with a brick which fell from a house-top, causing fracture of the skull. The skull was trephined, and the splinters of bone removed, but some time after the wound had healed she began to have attacks of epilepsy, for which ordinary treatment was unavailing, so the doctor finally operated on her, with an entirely successful result. As a result of his re-

searches on the subject, the author had found that lesions in the frontal and parietal regions are followed usually by the same symptoms, and that over fifty per cent. of the lesions in these regions are followed by epilepsy, which, later on, is complicated by insanity. Trephining at the site of the lesion and removal of the cicatrix is usually followed by complete relief.

At the Afternoon Session, the first paper presented was on "Fistula in Ano of the Horse-Shoe Variety," by Samuel Benson, M. D., of London, England. The object of the paper, as stated by the author, were: first, to point out that an important cause of the failure of the operative treatment of anal fissure is the presence of a co-existent horse-shoe fistula, left unrecognized and untreated; second, to define what is meant by a horse-shoe fistula and to comment upon the different kinds of horse-shoe or semi-circular fistula met with in practice.

Fissure is such a common complaint that doubtless cases have come under the notice of all present. This malady if taken early is very amenable to medicinal treatment, but in many cases, especially in females, the disease is allowed to progress for some length of time before it is brought to the notice of the surgeon, when some operative treatment then becomes necessary. There is a form of fistula, horse-shoe or semi-circular in shape, viz.: the blind internal horse-shoe fistula, which, though far more common than the complete horse-shoe fistula, is not referred to in any books that I have consulted. Some writers mention the blind internal fistula, which commences in an abscess, but the fistula referred to by the speaker does not commence in an abscess; it is merely a subcutaneous ulceration extending between and separating the mucous from the muscular coat of the bowel, just inside the anus, and usually arising in a fissure that has been of some months duration. A fissure that has been neglected or treated alternately by caustics and emollient ointments soon drifts on to the formation of a painful rectal ulcer, its base of an ashy gray appearance and the edges of the sore well marked.

While forcibly dilating the sphincter, it is quite possible that the mucous membrane may sometimes be torn from the sphincter muscle, especially around the parts near the anal ulcer and a sinus made traumatically; therefore when the patient is under an anæsthetic, an examination with a blunt-pointed probe should be made at the base and sides of the fissure before the sphincter ani is

interfered with. A blind internal fistula can then sometimes be demonstrated.

Horse-shoe fistulæ, as at present understood, are complete fistulæ, the external opening being situated on the opposite side of the bowel from the internal opening. This form of fistula is rare, having been found five times in 750 cases of rectal disease.

From these cases we gather that fistula in ano of the horse-shoe shape may be complete or incomplete. They may be complicated with prolapsus of the bowel. The most usual complication is anal ulcer. Sometimes polypus is also found. The average age of the patient is 35 years, males and females being attacked indiscriminately. The average number of days in bed is 14. If a correct diagnosis is made, the treatment consists of laying open the sinus and paring the edges with scissors, dividing or paralyzing the sphincter muscle and packing the sinus systematically with cotton-wool to prevent the edges sticking together, and thus getting the wound to heal from the bottom.

A paper by Arthur Norton, F. R. C. S. London, England, was then read by the Secretary in the absence of the author. It was entitled "Remarks on Rodent Ulcer of the Rectum." In it the author declares that there is an ulcer of the rectum, persistent, unyielding to treatment, advancing to complete stricture of the rectum, and usually appearing in a person after the age of 30 years. The ulcer begins immediately within the anus, but after a time extends and completely surrounds the rectum; it is accompanied by pain, which is not usually severe, and as the ulcer extends up the rectum, contraction takes place, with all the signs of stricture. Treatment by dilatation sometimes relieves for a time. From the clinical features of the disease, and the microscopical characters, the author was of the opinion that the disease was identical with rodent ulcer, and suggested that further investigation into its pathology be made.

The discussion which followed related to the treatment of fistulas in general, and was participated in by Dr. Foster, of Beirut, Syria; Dr. Quimby, of Jersey City, and Dr. Grant (Bey), of Egypt, who all related cases and agreed as to the proper method of treatment.

Dr. Grant (Bey) then read a paper entitled "Report of Some Cases of Liver Abscesses and Their Treatment," in which he expressed as the result of his experience, the opinion that in all cases of liver abscess we should first aspirate the abscess, and, if that was not followed by cure, then lay

the abscess open by a free incision, and in extreme cases excise a portion of the ribs (one or more) over the site of the abscess, so that free access might be had for clearing out the abscess cavity thoroughly with antiseptics.

In the discussion which followed, Dr. Winslow, of Baltimore, Dr. Pascal, of Mexico, and Dr. Moore took part, and while all agreed as to the principle of treatment, each had his own particular way of arriving at the result.

Dr. Lewis H. Sayre then followed with a paper on "The Treatment of Psoas Abscess by Posterior Lumbar Incision," in which he strongly insisted on early and free posterior and anterior incision in these abscesses, to be followed by thorough drainage.

Dr. Edmund Owen, of London, opened the discussion which followed, and spoke long and earnestly, strongly deprecating "ostrich surgery" in these cases, and advising early opening of the abscess, with free drainage.
